IN September last the practitioners residing in the district of Clutton, which comprises the villages of Midsomer Norton, Radstock, Peasdown, Paulton, and Tinsbury, in the area of the Bath and Bristol Branch of the British Medical Association, made a request to the friendly societies of that district for increased remuneration. The rate asked for was 5s., instead of 4s. per annum, for adults, and 2s. 6d., instead of 2s., for juveniles. The district is a heavy one to work, and the collieries furnish a number of serious cases. The reasonableness of the demand may best perhaps be gauged by the modesty of the remuneration asked for juveniles, for it is not the experience of the profession that children require less attention than adults. The request was refused by the majority of the societies, and the local medical men, who are unanimous, terminated their engagements. The friendly societies have since started the Radstock and District Medical Institute, and succeeded in obtaining a medical man to undertake the duties from March 25th last. We hear that the usual difficulties incident to an institution of this kind are already being experienced, and that a new doctor is wanted by the institute. Carried on as it is under conditions disapproved not only by the medical men of the immediate neighbourhood, but by the Bath and Bristol Branch of the Association, representing the medical profession of those cities and of the surrounding districts, it is probable that the misguided members of the friendly societies will soon see reason to regret the establishment of the institute. Apart from the probability of a succession of new doctors, no institution of this kind can offer such good value in medical attendance as the profession of the Clutton district did, as for many years the medical work of the friendly societies has been "pooled," the members having choice of practically all the local doctors at a very modest rate of payment.

THE EUGENIC VALUE OF CRIMINALS.

AMONG the many points of view from which the criminal class may be regarded is that of the value to be assigned to it when drawing up a balance sheet of the physical assets of the nation, and this in effect was the text of a discourse delivered by Dr. W. C. Sullivan, of H.M. Prison, Holloway, at the April meeting of the Eugenics Education Society. As he stated, any attempt to assess the value of criminals from the point of view of eugenics involves the measurement of what is a purely sociological group by a biological standard, and hence fallacies and confusion must arise unless sociological data are rearranged on biological lines, sufficiently at any rate to permit of criminals being classified psychologically. While pointing out that as this step has not at present been taken it is not yet possible to determine the eugenic value of members of the criminal class on really scientific lines, Dr. Sullivan maintained that it might be argued in tentative fashion that all the phenomena of crime indicated a strong probability that criminals in their innate characteristics do not differ essentially from the average man. He suggested, too, that if

crime were roughly compared with some bio-social entity such as insanity, in which the influence of innate tendency was potent, the conclusion might be drawn that criminals were made rather than born; or, in other words, that crime was the direction given by environment to relatively normal aptitudes. Though criminal conduct is often associated with defective organization, Dr. Sullivan held that even then the criminal conduct was the outcome not of a specific tendency to crime, but merely of a general debility of mind most marked, perhaps, in the sphere of impulse and feeling. So far, therefore, as its negative indications are concerned, eugenicists need apparently concern themselves only with the minority of the criminal class, and with that merely as part of the general problem of feeble-mindedness. Nevertheless, the remainder—possibly a majority of the criminal class—still have some interest for eugenicists, for Dr. Sullivan was probably right when he suggested that in the conditions prevailing in the lower strata of society there is, perhaps, a tendency for some of the best physically endowed youths to be directed into criminal courses. From this it would follow that measures commonly taken by society to suppress crime may be operating in such fashion as to impoverish the race by discouraging stocks in which energy and initiative are most abundant. If this be the case, it is clear that any method of treating crime likely to prevent the development of criminal habits in adolescents who are physically well endowed but show a tendency to drift into an antisocial career, ought to have a distinct eugenic value. Such a system, Dr. Sullivan contended, is the Borstal system of treating young criminals, and on this account he holds it to have a special claim on all interested in the physical welfare of the race.

IN THE NAME OF THE PROPHET—SOAP!

IN the classic legend of the Great Panjandrum it is related that a great she-bear, coming down the street, popped its head into a window and exclaimed, reproachfully, "What, no soap!" If this devotee of cleanliness had only known the right place to go to, she would not have been disappointed. But perhaps *Nash's Magazine* did not exist at the time. At any rate, there would be no excuse for any one making the same complaint now. We know nothing ourselves of the periodical in question, but two or three correspondents have called our attention to the following advertisement which has appeared therein:

63, Harley Street, W.,
December 18th, 1908.

Messrs. ———.

Dear Sir,—Thank you for the samples of soap you so kindly sent me. I feel in honour bound to tell you that of all the ENGLISH SOAPS I examined by my Hydrolysis test as published in the *Chemical Trade Journal*, December 12th, 1908, your soap called "Buttermilk Complexion" was far and away the best of THE ENGLISH SOAPS, judged from the standpoint of slow and equal hydrolysis and copiousness and fullness and maintenance of "lather." This is not a testimonial, but a statement of sober fact which I feel bound to furnish you with in return for your courtesy. Please make a point, if you find this plain statement of any use to you, to beware of anyone being under the impression that I am in any way fiducially interested in giving you this statement. Please accept this as it is meant and believe me yours very faithfully.

F. W. FORBES ROSS, M.D., F.R.C.S. Eng.,
D.P.H., etc.

This "statement of sober fact" is evidently considered so valuable by the highly respectable firm which sells the article praised that it is reproduced in facsimile. The soap may, for all we know to the contrary, have all the virtues which the author "feels bound in honour" to set forth. His appreciation of the soap is evidently as genuine as it is

disinterested; he might, in fact, say of it what Montrose said to his mistress:

I could not love thee, dear, so much
Loved I not honour more.

Of course we accept the author's assurance that he is not in any way fiducially interested in testifying to the fine qualities of the soap which has had the good fortune to gain his esteem; this we do all the more readily as the expression seems to us to have no particular meaning. Still, "fiducially" is, like "accommodated" according to Bardolph, "a word of exceeding good command," and such as a writer of a testimonial—we beg pardon, of a statement of sober fact—may use. If Dr. Forbes Ross were asked to define exactly what he means by it he might answer, after the manner of Falstaff's comrade in regard to the word which won the approval of Justice Shallow: "Fiducially interested; that is when a man is, as they say, fiducially interested; or when a man is—being—whereby—he "may be thought to be fiducially interested; which "is an excellent thing." There are, to be sure, old-fashioned persons who, having regard to the dignity of the profession, may not look upon the publication of a letter by a medical man in praise of a soap in which he is not "fiducially interested" as an excellent thing. The hucksters of Constantinople used to cry, "In the name of the Prophet, figs!" But even a prophet of the Yellow press, if he happens to be a "Harley Street specialist," should not cry in the market place the soap of a firm which sends him samples out of mere kindness.

POISONING BY CARBONIC OXIDE.

DISUSED colliery workings are sometimes allowed to be on fire for months or years; when this happens the products of slow combustion accumulate, and as the surface of the soil subsides, find their way through fissures to the surface of the earth: in this way they may gain entrance to houses through cellar drains or imperfectly cemented foundations. An accident of this kind is reported to have occurred at Cradley Heath, near Birmingham, involving the poisoning of eleven persons living in a row of six cottages built in 1897 on newly-made ground. As is usual in these singular cases it was only the ground floor rooms that contained enough gas to produce serious symptoms, so that as the occupants were sleeping upstairs they were not affected until they came down in the morning. A man named William Lloyd got up to go to his work, and was found by his wife and daughter, when they came downstairs, lying on the floor in what they thought was a fit. Summoning a neighbour, he was carried up to bed and a doctor was sent for. Some hours later Lloyd recovered and shouted to his wife for something he wanted, but getting no answer he went down and was horrified to find his wife, son, and daughter lying unconscious on the kitchen floor. Medical assistance was obtained and an examination made of the adjoining houses, when it was discovered that seven other persons were either unconscious or more or less stupefied. The majority soon recovered, but Lloyd's wife and daughter had to be removed to the Guest Hospital. One of the medical men, Dr. Kelly, had a narrow escape from a serious accident, for while he was carrying a child from a bedroom he was overcome by the gas and fell downstairs, fortunately without sustaining injury. Dr. Tibbetts placed a bird on the steps of one of the cellars, and within five minutes it expired; a canary in another house died, and a dog was discovered to be unconscious. There are said to be signs of a subterranean fire close

to the property, and, acting on medical advice, the occupants have temporarily abandoned their houses, which have been taken charge of by the sanitary authority.

LONGEVITY AND SANITATION.

BULLETIN No. VIII of the Census and Statistics Office of Canada consists of two papers read by Dr. Archibald Blue at the McMaster University Convocation and the last annual meeting of the American Public Health Association at Winnipeg respectively. The first paper deals with the effect of modern sanitation, not merely in lowering the death-rate, but in raising the average age at death of the adult population of a country. The two effects, though of course closely connected, are distinct. By a careful collation of the figures derived from registration statistics and census returns, Dr. Blue arrives at some very interesting results. In 1871 the mean age of the living was 23.50 years; in 1901 this had increased to 26.79 years, representing for the population of Canada 17,618,000 more years of life than would have been lived had the average duration remained what it was in 1871. This great increase of life Dr. Blue claims to be "a gift " that Nature has bestowed on a people who have discovered "covered and who submit to her laws." Taking as one group males from 15 to under 65—that is, the wage-earning period of life, Dr. Blue finds that the members of this group increased from 5,422 per 10,000 of all ages in 1871 to 6,074 in 1901. Assuming a dollar a day for 300 days as an average annual wage, this increase in the adult male population represents an increase of \$53,146,200 in the year, which Dr. Blue rightly considers to be a strong argument for the economy of sanitation. Dr. Blue's second paper deals with the sanitary problems to be encountered in the development of the immense new provinces of Saskatchewan and Alberta, in which the population has increased in five years from 419,512 to 808,863, or 92.81 per cent. The need for sanitary education in such a population is exemplified by the fact that only a few years ago a "progressive town" in one of these provinces took its water supply from a river at a point below that at which its sewage was discharged into the same stream! Altogether this pamphlet contains a great deal of interest to sanitarians and statisticians.

DECLINING BIRTH-RATE IN AUSTRALASIA.

THE continued decline in the birth-rate in the Australasian Commonwealth is attracting the attention not only of moralists but of statesmen. We learn from the *Australasian Medical Gazette* that at a recent session of the Victorian Anglican Synod the matter was discussed, and it was decided to invite the co-operation of the Victorian Branch of the British Medical Association in endeavouring to induce the Government to take some steps in the following directions: (1) That the manufacture and sale of preventive or abortifacient drugs and appliances be prohibited by law. (2) That advertisements of such drugs and appliances be prohibited. (3) That accommodation houses, nursing homes, and the like be placed under the supervision of the Department of Public Health. (4) That the police be instructed to report all infringements and suspected evasions of the law. (5) That the Church of England invite all other churches to co-operate with her in a vigorous crusade against an evil which the law cannot cope with unless the moral force of religious belief and action is behind it. (6) That medical men and chemists (wholesale and retail) be urged to lend their assistance in crushing out of existence practices which must, if allowed to con-

tinue and grow, weaken the fibre and minimize the strength and vigour of our national life. (7) That careful and systematic inquiry be made as to the effect of modern athletic exercise on young women.

A MENTAL HOSPITAL.

THE need of a hospital for the observation and treatment of patients in the early stage of mental disorder is making itself acutely felt in New England. We learn from the *Boston Medical and Surgical Journal* that the Massachusetts Legislature having failed to act before the expiration of options on certain property in Boston and Lexington, upon which it was proposed to build hospitals for mental disease, the State Board of Insanity, through a special report, has asked total appropriations of £30,000 for a similar purpose. Plans for a five-story building have been drawn up, and the urgent need of the hospital is set forth in the report. We commend this example to the imitation of the London County Council, which surely has plenty of sites to choose from. The evil of delay is shown by the failure of the Massachusetts Legislature to take prompt action in a matter which should have been treated as urgent.

THE next session of the General Medical Council will be opened on Tuesday, May 25th, when the President, Sir Donald MacAlister, K.C.B., will take the chair at 2 p.m. The Glasgow Faculty of Physicians and Surgeons has appointed Dr. David N. Knox, late Surgeon to the Royal Infirmary, and Professor of Clinical Surgery, St. Mungo's College, Glasgow, to be its representative on the General Medical Council, in succession to the late Dr. Lindsay Steven.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Budget.—All last week was overshadowed by the introduction of the Budget, which occupied in its exposition some four and a half hours on Thursday. There are only a few points in it of medical interest. In conjunction with the proposed tax of 3d. a gallon on petrol used for motor vehicles there is the remission of half the new tax on motor cars in favour of the medical profession. The proposal to allow a reduction of £10 of taxable income as regards income tax for each child under 16 years of age for taxpayers whose income does not exceed £500 per annum is an interesting novelty. With a falling birth-rate in this country, the loss to the Exchequer may possibly be balanced by a great and national gain. The increase of the income tax from 1s. to 1s. 2d. will affect earned incomes over £3,000 a year and all unearned or partly unearned incomes. In all cases of earned incomes not exceeding £3,000 the tax will remain as at present—9d. in the £ up to £2,000, and 1s. between £2,000 and £3,000 per annum. The increased duty on proof spirit will add to the price of many medicines and so fall rather heavily on hospitals and some practitioners.

Antivivisection.—The opponents of vivisection show signs of activity in the House of Commons, and the Dogs Exemption Bill recently introduced gave evidence of the fact last week. The close of the discussion on mining accidents before 11, and the withdrawal of the second motion on the paper left some ten minutes on Wednesday night for private members' bills, and the Dogs Exemption Bill was moved without a word of explanation by its promoter, Mr. Ellis Griffith. For a moment or two it looked as if the bill might pass *sub silentio*; and then Mr. Samuel rose on behalf of the Home Office to oppose the second reading, mainly on the ground that the Royal Commission had not yet reported. While he was speaking, Mr. Whitley, who had been out to get a copy of the bill, rose and said that the bill which the House was

asked to read a second time was not yet printed! The Speaker, thus appealed to, ruled that the fact of the bill not being printed was not an objection which he could take against the bill, but was one which might very probably weigh with the House. Mr. Samuel then moved that the debate be adjourned, so that it might be resumed when members could make themselves acquainted with the proposals of the bill. Sir F. Banbury spoke against the adjournment, and asked for a division that night. Mr. John Ward said his opinions on this matter had been considerably modified by his experience on the Commission, and he supported the motion for the adjournment, which, however, was not put, as 11 o'clock struck and the debate stood adjourned. Thus the attempt to pass a bill without any explanation of its contents and before it was printed was happily foiled.

Medical Officers (Scotland).—Mr. Cathcart Wason asked the Lord Advocate, last week, if he could state what parish councils had opposed granting to Poor Law medical officers protection against arbitrary dismissal and the same privileges as were enjoyed by medical officers in England and Ireland. Mr. Ure answered that the proposal had not, so far as he was aware, reached a stage which had provoked an active expression of opinion on the part of parish councils; and on this point he could add nothing to the reply given recently. Mr. Wason then asked the Lord Advocate if he was aware that in several districts in the Highlands and islands the poor had suffered from the action of certain parish councils in their treatment of medical officers; and if, in view of this fact, and that the question had been brought up at every election during the last ten years and that candidates invariably had expressed themselves favourable to a proposal which would indirectly benefit the poor, he would reconsider the position. Mr. Ure replied that he was not aware of any case in which the poor had suffered through the action of a parish council in the treatment of their medical officer. If the hon. member would specify any such case, full inquiry would be made by the Local Government Board. He was not aware that the question had been brought up at every election during the last ten years, and that candidates invariably had expressed themselves favourable to a proposal which would indirectly benefit the poor. Mr. Wason pushed the matter further home by asking if the proposal in the Education Act of last year giving teachers the right of appeal against arbitrary dismissal had been opposed by any school board in Scotland, and on what grounds were medical officers to be refused the same position as teachers. The Lord Advocate admitted that he knew of no protests from school boards as regards rights given to teachers under the Education Act, but he would not admit that the two cases were parallel.

The Sewage Disposal Commission.—In answer to Mr. Carlile, Mr. John Burns stated last week that the Royal Commission on Sewage Disposal was appointed in 1898. The total cost up to March 31st last was £56,061, including the net cost of stationery and printing, but excluding the cost of accommodation. He understood that an estimate had not been framed of the future expenditure which might be required. The Local Government Board were acting on the recommendations made by the Royal Commission in its fifth report. It was the Board's practice to advise local authorities to carry out these recommendations, but it had not issued any regulations on the subject.

The Belfast Health Commission.—In reply to Mr. Devlin, Mr. Birrell said that the recommendations of the Belfast Health Commission were so varied and complex that it was impracticable to give a general answer which would accurately cover all details. The corporation had dealt with certain matters pending the issue of the report of the Commission, and had put other matters in train since its issue. The Local Government Board, moreover, after considering the reply of the corporation to the report of the Commission, had addressed the corporation on March 13th last with regard to such of the recommendations as did not appear to have received suitable attention.

Workhouse Maternity Wards.—Mr. Cooper asked a question about a patient in Hammersmith workhouse who was put to do manual work fourteen days after her confinement. Mr. Burns answered that he understood the question referred to the case of an unmarried woman who was admitted to the infirmary of the parish of Hammersmith on March 3rd last and confined on the following day. He was informed that it was not the fact that the woman was mounted on steps and set to wash the paint on the walls. The woman left the infirmary on April 3rd, and was believed to have been married two days afterwards. He did not understand that she was ill and under treatment other than for a normal confinement before leaving the infirmary. There were no rules of the kind referred to, and at the Hammersmith infirmary all work performed by the patients was stated to be purely voluntary and of a very light character.

Small-pox at Bristol.—On Tuesday Mr. Burns said, in answer to Mr. Lupton, that two nurses at the hospital, while attending cases of small-pox, had slight attacks of an illness which was thought to show the initial symptoms of small-pox. Neither had an eruption of any kind, and both were well within three or four days. They had been revaccinated within two years, but he was unable to say from what source the lymph used was obtained. In answer to another question, Mr. Burns said that any comparison between vaccinated and unvaccinated children in relation to this matter should be made in respect of those children only who had been exposed to infection. At Bristol the persons who suffered from small-pox or were in contact with them were so carefully supervised that few unvaccinated children were so exposed. Of the children under 14 who were exposed to infection 9 were attacked by the disease. Of these 9, 2 had been vaccinated. Both attacks were abortive. The remaining 7 children were unvaccinated, except that 2 of them were vaccinated during the incubation of the disease. Of these 7, 3 died, all of whom suffered from confluent or black small pox.

The Rats (Destruction) Bill.—A bill to provide for the destruction of rats has been introduced by Sir Charles McLaren, and is founded on similar lines to legislation now in force in Denmark, Hong Kong, Bermuda, and other States which has for its object to save the vast destruction of foodstuffs and other property caused by rats, which amounts to many millions of pounds sterling in every year. Private efforts have failed to reduce their numbers owing to the lack of proper organization and adequate resources. This bill is intended to arm public authorities with powers to cope with the evil, while protecting private interests from any resultant damage. The sanitary inspector or the inspector of nuisances will be the public ratcatcher under the bill unless the local authority appoints a special officer.

Sleeping Sickness in Nyassaland.—In answer to Mr. Rees, who asked what steps had been taken to preserve Nyassaland from sleeping sickness, Colonel Seely said that the agreement between England and Germany related only to Uganda and German East Africa. So far as Nyassaland was concerned, he was glad to say that the extensive investigations which were being made in that Protectorate had failed, up to the present time, to reveal the presence of the tsetse fly which transmits the disease. These investigations would be continued, but there was good reason to hope that Nyassaland was not exposed to the risk of an epidemic similar to that which had wrought such havoc in Uganda. In answer to a further question, Colonel Seely said that the fly did not, he thought, travel very far from its particular place. On the whole question, he would refer to the many reports which had been issued from the Colonial Office on the subject. The Government would do all they could in the matter, but there was not much fear at present of the disease spreading to Nyassaland.

Beri-Beri.—Mr. Cooper called attention last week to the views of Dr. Braddon on uncooked stale rice being the cause of beri-beri, and Mr. Churchill replied that he was

aware of the theory held by Dr. Braddon and other medical men that beri-beri was attributable to the consumption of uncooked stale white rice; and of the investigations into the question which were being conducted in the Federated Malay States. The Board of Trade were in communication with the Royal College of Physicians in regard to the steps to be taken for the prevention of the disease on board ship, and when their views had been received the suggestion requiring that only cured rice should be used for the food of Lascars on British ships would be considered.

Fever among Civil Population in Malta.—Last week Colonel Seely stated, in reply to Mr. Lupton, that the number of cases of Mediterranean fever and of simple continued fever among the civil population of Malta in the years mentioned was as follows:

Year.	Mediterranean Fever.	Simple Continued Fever.
1897	568	107
1898	510	125
1899	822	114
1900	642	89
1901	624	60
1902-3 (financial year)	595	63
1903-4	573	35
1904-5	663	25
1905-6	822	22
1906-7	714	42
1907-8	501	5
1908-9	495	11

The Opium Traffic in Ceylon.—Mr. Walter Roch asked the Under Secretary for the Colonies whether the Ceylon Government had postponed the closing of its licensed opium shops during the present year pending a reference to the Secretary of State; and whether a statement had been received by the Secretary of State from three non-official ex-members of the Ceylon Legislative Council protesting against further delay in carrying out the policy unanimously recommended by the local opium commissioners in their report at the end of 1907? Colonel Seely replied that the facts were as stated in the first part of the question, but he should explain that the reason for the delay was that a difficulty had arisen as to the regulation of the supply of opium for medicinal purposes to the Vederals, or native doctors, of whom there was a large number in the Colony. This difficulty had led to a further reference to the Secretary of State, who was now in communication with the Governor as to the best means of surmounting it. As regards the second part of the question, the Secretary of State had received the statement referred to, but for the reason already given had been unable as yet to take action in the direction suggested by the signatories.

The Death-rate in the Transvaal Mines.—In reply to Mr. Fell, Colonel Seely said on Tuesday that the death-rates were: Black, 31.601; Chinese, 6.788. The Chinese rates were habitually lower than the natives, but the native death-rate showed a considerable increase. Inquiry would be made as to the cause of this increase. He regretted to say that the increase in black deaths was considerable; the decrease in the Chinese deaths was obviously to be expected owing to the rapidly diminishing numbers of the Chinese. He should have thought it was sufficiently obvious that the number of Chinese persons liable to diseases connected with the mines must be much less. They must by this time be nearly all dead or returned to China. In answer to a further question, he said that it did not appear that the increase in the black death-rate could be attributed to the labourers having been drawn from a different area.

Sydney.

[FROM OUR SPECIAL CORRESPONDENT.]

NEW SOUTH WALES BRANCH.

THE annual meeting of the New South Wales Branch of the British Medical Association was held on March 26th, when the retiring President, Dr. G. H. Abbott, delivered his address. He rehearsed some of the important matters which had engaged the attention of the Branch during the past year, and sketched out a programme of work for the future. Naturally one of the most important matters referred to was the dispute at present in progress between the friendly societies and the British Medical Association (New South Wales Branch) with regard to the enforcement of the wage limit. At the meeting of the Australasian Medical Congress in Melbourne last year some resolutions were passed agreeing to the necessity of enforcing a wage limit in all contracts with the friendly societies, and fixing a limit of £204 per annum. At a general meeting of the members of the New South Wales Branch of the British Medical Association held on December 29th, 1908, the following resolutions were passed:

That the wage limit, as adopted by the Australasian Medical Congress and accepted by the delegates of the lodges of the Friendly Societies' Association in conference with the Council of the New South Wales Branch of the British Medical Association on December 31st, 1906, and February 28th, 1907, be enforced in the metropolitan area from January 1st, 1909.

That the members of the Branch pledge themselves to support all members who determine to enforce the model lodge agreement adopted by the Branch on May 10th, 1907.

This attitude on the part of the lodge doctors has aroused a good deal of opposition on the part of the lodges, and at a meeting of the delegates of the Friendly Societies' Association some strong language was used as to what should be done to bring the British Medical Association to its proper senses! Dr. Abbott, in his address, reviewed the position of affairs at present, and urged upon all the members the necessity of standing firm in their demands, as there was no doubt that in the end they would secure the recognition of the wage limit.

Another matter to which Dr. Abbott referred was the proposal to acquire a site in the centre of the city, and to erect on it a building for the Branch. It has long been felt that this step is necessary in the interest of the members of the Branch, as at present it has no building of its own suitable for a meeting hall, library, reading room, etc. The proposal has been taken up rather enthusiastically, though it is recognized that a large sum of money will be required to do all that is suggested. A site is now under offer to the Branch for £11,000, and it is estimated that another £11,500 will be required for the erection of the building. There is every reason, however, to hope that by the time the next congress meets in Sydney in 1911, the New South Wales Branch will have a building worthy of the Branch and of the Mother City of Australia.

At the same meeting Dr. Richard Arthur, M.L.A., of Sydney, was elected as the Representative of the Branch at the Annual Representative Meeting in Belfast next July, and Drs. Odillo Maher and Watson Munro were elected as delegates to the Annual Meeting of the parent Association. Dr. H. C. Hinder was elected President, and Dr. J. A. Dick, Vice-President of the Branch for the ensuing year. The Treasurer, Dr. W. H. Crago, presented his statements of the accounts of the Branch and of the *Australasian Medical Gazette*, which showed a very favourable financial position.

THE FRIENDLY SOCIETIES.

Some idea of the extent of the operations of these societies in this State may be gathered from the annual report of the Friendly Societies' Association, which was presented at a meeting of the association held recently. At the end of the year 1907 the membership of the friendly societies was 116,985, an increase of 10,307 on that at the end of the previous year. The number of societies was reduced to sixteen, owing to the absorption of the old Protestant Alliance by the United Ancient Order of Druids. There were 1350 lodges and 116,985 members. The

receipts were £434,000, making the amount of funds £1,171,343. The amount of sick pay was £96,239; the funeral benefits £24,336; and the medical benefits, £110,894. The average value of the funds per member was £9 10s. 2d. From these figures it is apparent that these societies made a profit on the year's transactions of £202,530, which proves conclusively that they could afford to pay their medical officers a considerable increase on the present rates and still make a handsome profit. But the lodge member who cries out loudly about the sweating of the labourer by the master dearly loves to sweat his medical officer.

PRECAUTIONS AGAINST PULMONARY TUBERCULOSIS.

It has long been recognized that the Blue Mountains in this State afford an excellent climate for persons suffering from pulmonary tuberculosis, and large numbers of patients resort thither every year. The Shire Council at its last meeting had under consideration a report from the clerk, in which it was pointed out that each year there seemed to be a greater influx of patients suffering from pulmonary consumption to the mountains, and as legislation to make this disease notifiable seemed as far off as ever, it was suggested that it should be dealt with under Section 6 of the Local Government Act. It was further stated that the present careless practices are causing great harm to this great Blue Mountain health resort. It was suggested that all property owners, agents, and others who were in the habit of letting cottages should be compelled to supply a list of such premises to the Shire Council for the purpose of inspection. Premises vacated, it was stated, should be properly fumigated. Eventually the council passed a resolution to the effect that consumption should be declared a notifiable disease, and that the Government be requested to take prompt steps to deal with the matter. A letter embodying this resolution has been sent to the Premier and to the member of Parliament for the district.

The Federal Minister of Home Affairs has approved of an official suggestion that all candidates for appointment in the Federal Public Service should in future be compelled to undergo examination by a Government medical officer. This action has been taken because of the number of medical certificates being sent in by Civil servants alleged to be ill. An inquiry has been made, and in one branch alone—the Melbourne Telephone Exchange—some extraordinary cases of prolonged sick leave were found.

The inquiry was limited to permanent officers of less than five years' standing. Several of these cases were found to be suffering from tuberculous disease, and it was pointed out that such persons rendered comparatively inefficient service, while the danger of contamination of the other officials was great. As it is not considered desirable that these persons should be in the service, the Minister has approved of the suggestion referred to.

THE CHRONIC PLAGUE.

Once again Sydney has been visited by an outbreak of the bubonic plague. Early this year some plague-infected rats were discovered on one of the wharves which has been the site of infection in previous outbreaks, and the Board of Health and the city health officials were alert, in view of the probable occurrence of cases of the disease in human beings. Some two or three weeks ago a case was reported from a flour mill in the city, and four other cases followed rather rapidly. The mill was inspected. It was badly infested with rats, and over two hundred dead rats were found under the flooring. Following on this discovery the Lord Mayor promptly suspended two of the city sanitary inspectors for neglect of duty, and proceedings were taken against the owners of the mill. Unfortunately two of the proprietors were infected with the disease, and both died from it. Two other cases were discovered on a steamer which arrived from the New Hebrides, and one of these patients has died. Towards the end of March two other cases were reported from amongst the employees of the City Mills in Sussex Street, in close proximity to one of the rat-infected wharves. These premises are reported to be structurally sound, but plague-infected rats have been discovered on the premises next door; and, as the business involves the handling of produce, it is supposed that infection has been conveyed in this.

FEDERAL QUARANTINE SERVICE.

A conference of the States Health Officials was held recently in Melbourne to discuss and report upon the details of administration of the new Federal Quarantine Act. A report was furnished to the Cabinet, and acting upon that the Cabinet has decided to call for offers from gentlemen who may be prepared to act as Director of Quarantine. The salary has been fixed at £1,000 a year, but it has not yet been decided whether the post shall be filled by a medical man or a layman, and it is said that this point will not be settled till the applications are before the Cabinet.

[FROM OUR SPECIAL CORRESPONDENT.]

DEATH OF PRINCIPAL MARSHALL LANG OF ABERDEEN.

THE announcement of the death, at the age of 75, of the Rev. John Marshall Lang, D.D., C.V.O., Vice-Chancellor and Principal of Aberdeen University, will be received with much regret. He had been ill for about three months, and after a temporary rally grew rapidly worse and died on the evening of May 2nd. The cause of death was anaemia of toxic origin. Previous to his appointment to the Principalship of Aberdeen University Dr. Lang held a leading position in the Church of Scotland, not only as the minister of one of the chief churches—the Barony Church, Glasgow, where he succeeded Norman Macleod—but also as an ex-Moderator of General Assembly and a great leader and debater in the Church courts. His appointment in 1900 to Aberdeen University by Lord Balfour of Burleigh, who was then Scottish Secretary, was the subject of much criticism at the time, and was received with considerable misgivings, not only in academic circles but by the general public. Affairs in Aberdeen University were not going in the smoothest way in 1900. The great extension scheme, when only half completed for want of funds, had practically come to a standstill, and there was a grave division of opinion as to the future of Greyfriars Church. These and other matters may have led Lord Balfour to introduce as head of the university one from outside its walls. However, it was not the appointment of an outside man that gave rise to the misgiving, but rather the doubt as to whether one who had up to the time of his appointment as Principal spent the whole of an already long life in the ministry of the Church, and who had never held a university office, would justify his selection at a time when the university affairs were in a notoriously troubled condition. Time proved, however, that the appointment was a wise one. In spite of a very hostile reception by the students on the occasion of his inaugural address, and at several graduation ceremonies thereafter, he ultimately gained for himself their sympathy and affection, for as time went on they realized the character of the man and his anxiety to promote their interests, so that in recent years even the rowdy enthusiasm of graduation day did not prevent respectful attention to his address as Vice-Chancellor at the close of the capping ceremony.

In regard to his position as head of the Senate, it has been stated that he was probably never quite at ease in the technical and complex work of university teaching under modern conditions, but that the Senate never enjoyed the services of a more helpful and conciliatory chairman, one who never failed to exhibit those qualities of impartiality, courtesy, tact, and knowledge of methods of debate which conduce so largely to fair and orderly discussion and to proper decision. In the work of the University Court Principal Lang had an opportunity of displaying his administrative capacity. He found the extension scheme languishing for want of funds, with a debt of over £20,000 on the extension already completed, and the Court stood committed to complete the extension by enclosing the front of the Marischal College buildings. How successfully the Principal devoted himself to the completion of the scheme is matter of recent history, fully demonstrated at the celebrations in 1906, in which he occupied a central position with striking dignity. Few who heard his address of welcome to the delegates from other universities and learned societies will ever forget

his great oratorical effort worthy of that unique occasion. Probably no Principal has enjoyed more popularity with the general community. Much of the ultimate success of the extension scheme was due to the way in which he enlisted the sympathy and services of the Lord Provost and town council and other corporate bodies in the interest of the university. He had not been long in Aberdeen before he gave ample evidence of his determination to be a working Principal of the university. His services were available for every scheme of social and religious organization and educational advancement. He responded to every call, and gave his services gladly. He enjoyed the social intercourses of life, and his after-dinner speeches—as, for instance, in Trinity Hall, of the Incorporated Trades, or in the Medico-Chirurgical Society Hall—were not less happily phrased than his more ceremonial deliverances. In many ways he was a remarkable personality, combining in a singularly attractive character a richness of genial humanity and grave dignity that well befitted the high offices to which he had been called, and all of which he adorned. In his public deliverances he was always appropriate, and few men could more correctly interpret the general feeling in saying the right thing at the right time in diction copious and polished, with fine rhythm and swing. There have been Principals of Aberdeen University more distinguished for scholarship and authorship, but there have been few of more varied culture and more eloquent, or who with more acceptance brought the university into vital connexion with the life of the city. His kindness, intense sympathy, affability and geniality were unfailing, and the whole bearing and quiet dignity of the tall, slightly stooping figure inspired respect. He possessed remarkable tact and capacity for dealing with men, and it was probably this feature of his character that made his principalship the success it has proved to be.

POST-GRADUATE CLASSES, TRINITY COLLEGE, DUBLIN.

THE arrangements for the annual classes for medical post-graduates at Trinity College, Dublin, have been completed. As in 1908, two courses have been organized for this year. The summer course will be held in June, and the autumn course will be given in the later part of September and the first week of October. A new feature in the syllabus for 1909 is the announcement of the delivery of a special lecture on cancer of the rectum by Sir Chas. Ball, Regius Professor of Surgery. Instruction is given in medicine, surgery, gynaecology, diseases of the eye, ear, throat and nose, in x-ray work, and in cystoscopy. Classes of a practical nature are also to be held in physiology, pathology, and anatomy.

One of the attractive features of the courses in past years is still retained. Members of the class may obtain rooms in college and dine on commons at an inclusive cost of £1 ls. a week. As the number of rooms available is limited early application is desirable. Additional details can be found in our advertising columns, or the complete syllabus can be had on application to the Honorary Secretary of the Post-Graduate Classes.

CHURCH TUBERCULOSIS CLASS IN BELFAST.

A tuberculosis class has been formed in connexion with Elmwood Presbyterian Church, Belfast. A room has been rented in the mission district, where the class meets weekly. The membership is limited to six, as the work is experimental. A doctor and the nurse of the Women's National Health Association attend the class, and the nurse visits the patients in their homes. Discipline is maintained, and a member has been dismissed for disobedience to orders. The patients have to keep a record of their case, and help is afforded to the very necessitous. This class is said to be the first of its kind on this side of the Atlantic, but the plan has been tried with success in the United States. Details are given in the April number of *Slainte*, the journal of the Women's National Health Association.

A SAD STORY.

The board of guardians for Ballina received recently from Dr. Laing, the dispensary medical officer, a letter from which we quote the following paragraphs:

Gentlemen,—I beg to acknowledge receipt of a copy of the Local Government Board report on the late inquiry held to investigate charges against me.

The fact of my trying to cope with the impossible for years did not weigh one atom in my favour. I have worked day and night for the past seventeen or eighteen years till, in the discharge of my duties, I contracted blood poisoning (last July two years). Since that time my health has been indifferent, and again in June last I got sepsis from another patient suffering from diphtheria, which put all hope of my regaining my former sound constitution out of the question. This attack also left me with a useless finger, and left my heart in a condition which absolutely prevents me ever undertaking any duty which would entail much physical or mental fatigue. As a matter of fact, it was against my medical advisers I was working when those reports were made. I had consulted Dr. Swann in August, and he forbade me to do any work for six months; but owing to the attitude of the Board, or on account of the extra expense, I said on October 1st I would take up duty and work till I fell. I knew I was killing myself by doing so, but for the last few months I felt it was no use courting disaster, and in justice to the poor and to myself, I had made up my mind to resign. I now, with the greatest regret, beg to offer you my resignation.

Then follows perhaps the most pathetic part of Dr. Laing's letter, in which he appeals to the guardians for superannuation, which if granted on the most liberal allowance permitted by the Civil Service scale would only amount to twenty-seven sixtieths of his salary of £120 a year. Fancy a salary of £120 a year for attending to a population of 18,480 persons scattered over an area of 73,811 acres, the dispensary tickets amounting in a recent year to 1,066 and the visiting tickets to 466!

At the inquiry referred to Dr. Laing was charged with neglecting two dispensary patients. The inspector who tried him found him not guilty in one case and guilty in the other, but having carefully read all the evidence as published we do not think any jury of his countrymen would have convicted upon it. Even then he might have escaped with a reprimand, but that he had been guilty admittedly of the more heinous offence of neglecting to write up his dispensary records for some months—records which no one ever looks at except an inspector, who takes a glance at them perhaps once a year.

It was admitted by the guardians examined at the trial that for sixteen or seventeen years no man could have discharged the overwhelming duties of this dispensary better than Dr. Laing, and that only for one year he had neglected them, owing, as he states, to his broken-down health, and he was for that neglect promptly called on to resign.

Dr. Laing complains that the inspector had his mind made up before he opened the inquiry. We should be sorry to think such was the case, but such suspicions are inevitable when the Local Government Board imposes upon the inspector in charge of a district the duties of prosecutor, judge, and jury combined. It would make no difference to the Local Government Board, and would certainly conduce to public belief in its impartiality if such inquiries, which in many cases would be more appropriately styled criminal trials, having regard to the punishments inflicted, were held by an official on its staff with some legal training and unconnected with the district, leaving to the inspector of the district the sole duty of collecting and presenting the evidence for the prosecution. Owing to the great increase in the number of these inquiry trials since the passing of the Act of 1898, public attention has been more directed to them, and the dissatisfaction with the slipshod methods in which many of them are conducted more frequently expressed. At the end of its report to the guardians the Local Government Board says:

If the guardians are satisfied by medical testimony that Dr. Laing is physically incapable permanently of the effective discharge of his duty, the Board would not regard the decision now arrived at by them as a bar to the granting of a superannuation allowance to him.

From the promptitude with which the guardians accepted Dr. Laing's resignation, and the fact that Ballina Union is next door to Castlereagh, we feel rather doubtful of Dr. Laing's chances, but hope for the best.

There is one thing this inquiry has brought to light, and that is the shocking injustice of expecting any man to discharge such duties on such a salary. If an Act of Parliament is needed to prevent English employers from sweating their employees, it ought in justice to be extended to the Irish Local Government Board and to Irish boards of guardians, who are—our Irish readers can supply the hiatus.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LIVERPOOL.

PRESENTATION TO THE MEDICAL OFFICER OF HEALTH.

On April 30th a meeting of the sanitary staff of the city was held in the Municipal Offices to do honour to the medical officer of health (Dr. E. W. Hope) on the occasion of his completing twenty-five years' service in Liverpool. Dr. A. A. Mussen, the assistant medical officer of health, who presided, presented Dr. Hope with an illuminated address and an antique silver tankard, and spoke of his distinguished services and the zeal which he showed for the highest interests of the staff. Not only were Dr. Hope's annual reports among the best of their kind, so that his position as an authority on public health was almost unique, but his evidence on sanitary matters was sought in the law courts and before Royal Commissions and Departmental Committees, while he was often consulted by Government officials. The prestige of his staff was now at the highest, and Dr. Hope was a chief who always gave credit to those who worked well for him.

Dr. Hope said that, while accepting the beautiful gift, it was difficult to realize that he was in his twenty-sixth year of service, while seeing present faces which had been around him all those years, and which were still so little changed. The most important duty of his early years as medical officer of health was to certify patients suffering from typhus fever. Within the first six months he certified more than a thousand such patients, but to-day typhus fever was looked upon as a rare disease, and as pointing to something which ought not to exist. Twenty-five years ago the city had no municipal hospital, and he had to depend on the good offices of the boards of guardians. Even when a city infectious hospital was opened in Grafton Street it was sometimes so difficult to induce a patient to go there that a magistrate's order had to be obtained and the patient compelled to enter the hospital. Nowadays, if the patient was not promptly taken to hospital, the relatives and friends wanted quickly to know the reason why. Twenty-five years ago there was no system of notification of infectious diseases, and his staff was only about a dozen. Since then, however, a series of Acts of Parliament, some originated by the Liverpool Corporation, had been put into operation, with a consequent increase of the health office staff, while the central growth and extension of the city from 450,000 to over 750,000 had been accompanied by an automatic multiplication of inspectors. The sanitary work of the port, through which as many as 400,000 emigrants passed in a single year, and the enormous importation of foodstuffs had led to increased work for inspectors, while the task of caring for the health of the children in the schools was only just beginning, and the notification of births would lead to still more duties being cast upon the health officer. What was there to show for all this sanitary zeal? The answer was that unhealthy conditions had been swept away which, if present to-day, would shock the public eye; so that on the negative side there was much to be credited to sanitation which was invisible. There was, however, one great fact to be proud of and to be seen—the remarkably improved health of Liverpool. It was by one continuous, united, concerted effort that improvement in the health of the city had been effected. The improvement had taken place not only in the old parish and parliamentary borough of Liverpool, but also in all the districts which had been absorbed in the municipal area. The Town Planning Act, which by the provision of wide streets and open spaces was to prevent a repetition of the errors of

the past, would result in a further great development of sanitation. Moreover, people were increasingly willing to listen to advice concerning their health and that of their homes, and he was glad to say the poor people were as amenable and as willing and as anxious to do what they could for themselves, in a sanitary sense, as any other class. In short, sanitary science had reached a stage after which the city and the nation would advance at an accelerated rate.

MANCHESTER AND DISTRICT.

THE REORGANIZATION OF POOR LAW MEDICAL RELIEF.

WHATEVER may be the ultimate outcome of the Poor Law Commission Report, there can be no doubt that boards of guardians throughout Lancashire and Cheshire have been roused by it to a remarkable degree. The more advanced and enlightened boards have been at some trouble to prove that they have already adopted many of the suggestions of the Commission, especially in discriminating and separating various classes of paupers, while even the less up-to-date boards are protesting as to what they will do as soon as possible. The Chorlton Board, however, has attempted to outbid the Commission itself by a resolution passed at its fortnightly meeting on April 30th. Armed with a resolution in his favour from the Medical Guild, Dr. Garrett, one of the board, proposed that the clerk be instructed to make representations to the Local Government Board that any person needing medical relief or free vaccination should be at liberty to select his own doctor, and that the fees should be paid according to a fixed scale by the guardians. Dr. Garrett said that it was a distinct hardship that poor people should be compelled, when they need medical relief, to go to the district medical officer, and it was specially objectionable in maternity cases. In addition, he thought it was unfair to general practitioners that they should be precluded from a share in the work. Such work ought not to be in the hands of a few members of the profession. The proposal was supported by Mrs. Lawson, a trained nurse and a member of the board, who said that the poor women viewed with horror the idea of having a strange doctor at their confinement. The resolution was passed unanimously, and it was further resolved to send it to all the local members of Parliament, the Poor Law Unions Association, and to all boards of guardians in the kingdom. The effect of this resolution would, of course, be to abolish the district medical officers, which, as the Majority Report suggests, would ultimately happen if the Majority scheme of medical relief on a provident basis were adopted. But the commission hardly goes so far as the Chorlton proposal, for in the Majority Report choice of doctor is not suggested for all paupers but only for those persons who have joined a provident dispensary. For the present, at any rate, non-members of a provident dispensary would presumably be limited to the district medical officers. Dr. Garrett's idea is that the difficulty under his proposal of having to compensate the district medical officers would be got over gradually by simply not appointing others when vacancies occur.

TREATMENT OF PHTHISIS UNDER THE POOR LAW.

At a Poor Law Conference of the North-Western District, held in Manchester on April 20th, at which about a hundred guardians were present, the report of a sub-committee on the treatment of phthisis was unanimously adopted. The report suggested that every effort should be made to form combinations of unions for providing sanatoriums, as was possible with the consent of the Local Government Board under the existing law. With regard to the outdoor poor it was suggested:

(a) That attempts should be made to secure active co-operation between the health authorities and the guardians in dealing with phthisical cases among the outdoor poor.

(b) That the guardians could do something to lessen existing evils by making additional grants of outdoor relief to phthisical patients conditional on such patients having separate sleeping accommodation.

(c) That leaflets containing instructions as to precautions to be taken, such as exercise, rest and ventilation, and advice as to the use of the most nutritious cheap foods, might be distributed by the relieving officers.

(d) That as the chief danger arises from the sputum, it might be lessened by the provision of pocket spittoons, paper handkerchiefs, and disinfectants.

(e) That hopeful cases should, where practicable, be sent to sanatoriums.

(f) That the guardians should provide their medical officers with facilities for obtaining, free of cost, bacteriological examination of sputum in suspected cases.

(g) That nurses with special knowledge of the treatment of phthisis should be provided periodically to visit and advise the consumptive poor.

As regards the indoor poor, it is suggested that special care should be taken to isolate all cases of phthisis, no consumptive patients being allowed in the general wards of the workhouse hospital, but that special wards with plenty of fresh air should be provided. In the smaller unions shelter-tents and temporary buildings might be erected in the workhouse grounds, while in the larger unions there should be special buildings of a more permanent character.

WALES.

THE EBBW VALE DISPUTE.

THE latest phase of the Ebbw Vale dispute may be gathered from the following paragraph, which we take from the *South Wales Daily News* of April 29th:

The first ballot on the Ebbw Vale doctor's fund question having failed to settle the vexatious controversy, a second ballot was taken, and the result was announced on Wednesday (April 28th). On the former occasion the ballot paper, it was contended, did not clearly state the issue. The result of this second ballot was: Against the reinstatement of Dr. O'Sullivan, 3,207; for reinstatement, 2,690; majority against, 517. The Cwm members of the fund, however, declined to fall in with the suggestion to take a second vote, and, it is said, will not abide by the result. Therefore, the protracted dispute promises to continue unless a mass meeting to be held in a few days comes to a decision.

WEST YORKSHIRE.

THE HYGIENE OF TRAMCARS.

IN fulfilment of a promise made by the Chairman of the Bradford Health Committee, Dr. Evans, M.O.H., has recently issued a report on the cleanliness and ventilation of the tramcars. Each car is washed at night with cold water and with soap and water once a month, and disinfected at regular intervals. The cars, however, are frequently overcrowded, but Dr. Evans does not consider this a fertile source of infection. The ventilating arrangements of some of the most recently constructed cars cannot be tampered with by the passengers, and this method will probably be adopted in future. Complaints are made that workmen in dirty clothing use the cars, and it is suggested that the Bradford Health Committee might urge the employers of labour to provide their workpeople with facilities for washing before leaving work. Complaint is also made that no effort appears to have been made to lessen the noise created by tramcars. In Bradford the tramcars, which run until after midnight and start again at 4.30 a.m., are a constant source of insomnia and nervous troubles. Why should not a concerted effort be made to try and run silent cars? Why not call together a conference of leading experts—engineers, electricians, tramway managers, and medical men—to consider means for lessening noise? In inviting tenders for the manufacture of tramcars, the silence of the running of the car might be made an important point. There is little doubt that this question of noisy streets is one of the problems of the future, but with foresight and energy it might before many years are over become almost a thing of the past.

COUNTY OF DURHAM.

WOLSINGHAM SANATORIUM FOR WOMEN.

ON May 1st the new Sanatorium for Women belonging to the Society for the Prevention and Cure of Consumption in the County of Durham was opened by Lord Barnard, the President of the Society, before a numerous company of the friends of the movement, amongst whom were representatives of local authorities and representative workmen of many miners' lodges, works, etc. Lord Barnard referred with gratification to the good work done at the sanatorium at Stanhope, and thought that the cult of the open window was beginning to spread to the masses. He stated also that at a meeting of a similar society at

Shrewsbury a little while ago the work and methods of the Durham Society had been most favourably referred to. The Rev. Dr. Randell, Rector of Sunderland, then offered a dedicatory prayer, and invoked a Divine blessing on the sanatorium. Dr. Robinson of Sunderland, the Chairman of the General Committee, gave a short account of the work of the society and of the Stanhope Sanatorium: already 1,100 people had been treated in it, and of these many hundreds had been restored to the ranks of workers. The society now had accommodation for 73 patients. He referred to the work of the sanatoriums as being a part of a wide and general programme to eradicate the disease from the county. He asked for assistance from the local authorities to establish, equip, and maintain a third sanatorium in which the advanced cases might be received, as from the point of view of the public health these cases were the most dangerous to the community. He concluded by stating that no risk was caused to the neighbourhood by a consumption sanatorium. During the nine years that the sanatorium had been at Stanhope, not a single instance had occurred of any of the staff having been attacked by the disease, but, on the contrary, they had all looked rosy and well. Neither had the death-rate from consumption increased in the district, and, as a matter of fact, last year there had only been one death from consumption in the Stanhope Urban District (population 2,006), and that occurred in a patient over 70 years of age. After a short speech from Dr. Mostyn, M.O.H. South Shields, a vote of thanks was moved to the Rev. Dr. Randell by Councillor Arthur Ritson, Chairman of the Sunderland Health Committee. Councillor Elliot of Gateshead moved a vote of thanks to Lord Barnard.

Correspondence.

COAGULATION TIME OF THE BLOOD.

SIR,—In your issue of April 24th, I am pleased to see that Dr. T. Addis, in his article on the "Clinical Methods of Determining the Coagulation Time of the Blood," quotes my method as being one of the most accurate. I regret, however, that he omits to say that the principle of McGowan's method, which he uses, is not only directly derived from, but the method itself is only a variation of the one which I described several years before McGowan published his. I first published the principle in a paper read at the congress at Lille in 1899. I further gave a demonstration of it at the International Congress of Medicine at Paris in 1900, in the presence of Sir A. E. Wright, who also showed his coagulometer. This method shortly is as follows:

The ear or finger is pricked, and the second drop of blood obtained is introduced into a tube 5 cm. long, and having an internal diameter of 1 mm., so that the column of blood occupies about 1 cm. of the middle of the tube. Two other similar tubes are filled with the third and fourth drops. These tubes are then placed in a glass box divided into two parts by a glass partition, in close proximity to the fine bulb of a special thermometer. This is graduated in tenths of a degree, and the temperature, 18.5° C, is marked by a red line. Contrary to what Dr. Addis says, it is not very difficult to supervise the box, and, by slightly warming or cooling, to keep it at a constant temperature, or with a variation of a few tenths of a degree.

The second and third tubes (containing the third and fourth drops), in which coagulation takes place in a slightly shorter time, serve to give warning of the approach of coagulation in the first tube (containing the second drop of blood), which it is then only necessary to examine every half minute in order to observe with ease the commencement of coagulation.

The coagulation time is indicated (1) by a tendency to adhesion of the column of blood to the walls of the tube. This indicates that coagulation is about to begin. (2) By the fine filament of fibrin, which is seen in the middle of the column of blood, when the tube is broken at the level of file mark made *previous* to the commencement of the experiment. It is also easy, if desired, by using the drops from a new puncture, to obtain an average coagulation time.

My method, therefore, is simple, does not require any expensive apparatus, and is exact, because the column of

blood is kept in close proximity to a sensitive thermometer beneath the eyes of the observer, who can easily maintain a temperature of 18.5° C.

Since 1900 I have perfected this method⁽¹⁾ by calibrating more exactly the tubes. The contents of tubes with an internal diameter of 1 mm. are brought to the same temperature as that of the receptacle with greater ease than when longer and larger tubes, such as Dr. Addis's, are used. Moreover, it would be exceedingly bold of any one to pretend that any of the methods used are absolute, since the blood is withdrawn at the temperature of the patient, who may be febrile, and comes into equilibrium with the external temperature with more or less ease, according to its physical properties. (2) By suggesting the use of short columns of blood in order to avoid the error caused by the unequal repartition of the fibrin in long tubes. (3) By making the method more sensitive by the use of the tubes which serve as indicators.

I have written this letter because the method which I have just described in brief has been borrowed by Drs. McGowan² and Addis, who have been satisfied with making a variation which is not only more complicated but more expensive, without even referring to my last work on this subject.

With apologies for transgressing at such length on the space of your columns,—I am, etc.,

SABRAZÈS,

Professeur Agrégé, Médecin des Hôpitaux de Bordeaux.
Bordeaux, April 28th.

SIR.—I think Dr. Mercier must be mistaken in his interpretation of the figures I gave in the paper on the relation between the administration of calcium and the coagulation time of the blood. I am unable to understand how he calculated that there was a "difference of 33 per cent, in coagulation time among 150 trials on different days."

What I said was that in 50 consecutive daily observations on the same person there was an average variation of 34 sec. from the mean, which was 9 min. 50 sec., and that the longest time was 11 min. 41 sec. and the shortest 8 min. 45 sec.

Again, he says "the normal margin of error is so wide, even on his own showing by his own method, that one would expect a wider variation in his results, which are quite remarkably uniform." But my results are not, unfortunately, so very uniform, and there is not much difference between the average variation from the mean in each case and the average variation of 34 sec. in the series of observations undertaken to determine the amount of experimental error. I have taken the trouble to work them out, and I find that they are 30, 25, 36, 26, 16, 26, 33, and 23 sec. That gives a total average variation of 27 sec.

I have constantly found that the blood which first leaves the wound is the last to coagulate. The reason, no doubt, is that fibrin ferment quickly forms and collects round the lips of the wound, and tends to shorten the coagulation time of the blood which follows. The results which are given were taken at all times of the day, and without any reference to meals, because when using another method more accurate than this modification of McGowan's, but inapplicable to clinical work, I found no difference between the coagulation time before or after breakfast, and the fact that the coagulation time is the same at all times of the day shows that food has no effect.³

Dr. Golla, working a modification of Buckmaster's method, has also come to the conclusion that the administration of calcium and citric acid has no effect on the coagulation time; so it seems to me that some other explanation must be given to account for the influence of calcium on certain cases of albuminuria, urticaria, chilblains, etc. There is a great deal of clinical evidence which goes to show that in many cases of such conditions the giving of calcium is followed by improvement. Netter⁴ has suggested that they may be due to a disturbance of the normal equilibrium between the amounts of the different inorganic salts in the tissues,

¹ *Folia Haematologica*, 1904, i, pp. 394-5; *ibid.*, 1906, iii, Nos. 7 and 8.

² *British Medical Journal*, November 30th, 1907, p. 1580.

³ *Quart. Journ. of Exper. Physiol.*, November, 1908.

⁴ *Compt. Rend. Soc. de Biol.*, 1907, p. 462.

the treatment of school children, with instructions to prepare an estimate of the cost of treating each of several diseases. The matter is thus left as follows: The Council has decided to treat the children by utilizing existing institutions and by making grants in return from the public funds. The latter, by the way, is in direct opposition to the almost unanimous opinion of the British Medical Association.

Following on the passage of this amendment, the authorities, permanent and other, of the Education Committee have approached the chairmen and secretaries of the London hospitals with proposals, and an informal meeting has been held at which a definite proposition was made, offering the hospitals 4s. 6d. a head for treatment. The response to this offer has, I understand, been of a varied nature, some agreeing to a definite remuneration per head, and others saying that if the Council subscribes special facilities shall be given.

In no case does it appear that anything has been said to the staff, or that they have been considered in the slightest degree.

As far as I can ascertain, they are in more or less complete ignorance of the matter. It seems to be taken for granted that the medical staffs will carry out any scheme that may be proposed by the committees and adopted by the boards of management. In fact, it was bluntly stated the other day: "The staffs are the servants of the boards of management, and if the boards say they must treat the children they must do so." Personally, I think it unlikely that the staffs will submit so easily.

In other words, many thousands, probably hundreds of thousands, of children are to be treated, as far as the medical profession is concerned, for nothing. There is no doubt that these children need treatment, but if they cannot afford to pay their own private practitioners, they should either be treated by the Poor Law or by means of special clinics officered by the medical staff of the Education Committee, who no doubt are able and willing to carry out the work in return for adequate remuneration.

Can there be a more flagrant example of exploitation than this proposal to utilize the services of the profession, without payment, to keep down the rates?

—I am, etc.,

London, W., May 1st.

H. BECKETT-OVERY.

PROFESSIONAL UNION AND THE BRITISH MEDICAL ASSOCIATION.

SIR,—I would like to offer my meed of praise for the valuable assistance rendered by our local British Medical Association. Twice within two years has it enabled me to uphold the dignity of the profession by resisting offers of remuneration inadequate for professional work.

In the first case the cordial support of my professional brethren enabled me to obtain 6d. a head more from a local club, and in the second case an insurance company offered me the position of local examiner—without, strange to say, ever suggesting I should take out a policy, but at the fee of half a guinea only up to a £500 limit. Again the services of the local British Medical Association were requisitioned, and, thanks to its support, the company have now agreed, less a trivial reservation, to pay a guinea fee for examination for any policy issued above £100.

These cases simply show what can be done by a little mutual co-operation.—I am, etc.,

Whitley Bay, May 3rd.

F. HORSEMAN.

THE EMMANUEL MOVEMENT IN AMERICA.

SIR,—During a somewhat brief stay in London it has been borne in upon the writer that a certain confusion exists between the principles and aims of the Emmanuel Society, of which Mr. Hickson is the head and chief exponent, and the Emmanuel movement which took its rise about three years ago in Boston, America, under the leadership of the Rev. Dr. Edward Worcester, Rector of the Emmanuel Church, in co-operation with some of the leading neurologists of that city, and which has spread rapidly through all the leading cities of the United States.

It should be clearly understood that the Emmanuel movement in America is not a faith-healing movement, as that phrase is commonly understood. It does not undertake the cure of any and all diseases, but only those of a

nervous or functional character. In this specializing of its efforts to alleviate suffering and cure disease it is not limiting the power of God, but attempts the humble task of learning His will as embodied in the ascertained facts known to medical science as the laws of health and disease.

Hence it does not act independently of, but in constant reliance upon and co-operation with, medical men. No case is taken for treatment unless first diagnosed by a competent physician, preferably a neurologist, who recommends it as likely to yield to the psychical and religious methods employed by the clergymen engaged in the work.

With very few exceptions the leading physicians everywhere in America have welcomed this movement, and given it their warmest support. No fees are charged by the clergy, who feel amply rewarded in the larger opportunity for service to their kind, and especially in the reconstruction of moral and spiritual character which the treatment almost invariably effects.—I am, etc.,

ALBERT B. SHIELDS, M.A., Harvard.
Superintendent and Chaplain of St. Luke's Hospital,
San Francisco, Cal., U.S.A.

THE BUDGET.

SIR,—Owing to the additional duty of 3s. 9d. per gallon on proof spirit, the price of many medicines is so materially enhanced that, in my opinion, it will, in many instances, be almost impossible for medical practitioners to undertake contract practice for sick clubs unless a proportionate increase—say of 1s. a year—is made in the capitation payments of members.

Rectified spirit has already been advanced 7s. a gallon, ether 1s. 9d. a lb., chloroform 1s. a lb., sal volatile 9d., sweet spirit of nitre 1s., and so on. Your readers are, unfortunately, only too well aware that the margin of profit from attendance on members of many sick clubs is so exceedingly small that it will be impracticable to meet this large increase in the drug bill save by an increased charge for attendance. I venture, therefore, to hope that the matter will be immediately considered by Branches of the British Medical Association and by medical societies generally throughout the country.

I am not, myself, in private practice, nor am I interested in any club.—I am, etc.,

Leicester, May 4th.

J. E. O'CONNOR, M.B., D.P.H.

RURAL DISTRICT NURSING ASSOCIATIONS.

SIR,—There is a nurse in this district who is supported under a provident system managed by a committee of ladies (wives of small tradespeople) and presided over by a lady in county society.

No medical man was ever invited to join the committee, or indeed to have any say in the management of the nursing club. We were, however, pestered to subscribe a guinea annually.

One nurse is kept; she is a certified midwife, and also does general nursing, but to all intent and purposes she is a general practitioner. She diagnoses cases and prescribes for them. Her fee for midwifery is 10s. She also poses as a kind of electrical specialist, patients being treated to a series of shocks from a small galvanic battery; for this quackery she charges from 2s. 6d. to 7s. 6d. a week. A vibrator also forms a valuable asset, chronic rheumatic joints being constantly "cured." She also specializes as a masseuse, treating dropsy by her "wonderful manipulations," to quote a patient's words.

As a gynaecologist she is second to none, and has prescribed and introduced a pessary for a patient of mine, a fee of 7s. 6d. being charged for her attendance. At midwifery she is "an expert," and I must be excused for quoting the following case. On a certain occasion she was engaged to attend the wife of a miller, a man in a position well able to afford to pay a fee of 2 guineas for a confinement. She proceeded to give the patient, a primipara, as far as I can ascertain, about half a wineglassful of ext. ergot liq., with the result that the labour was very considerably hurried. The child was born half dead, and the condition of the patient's perineum can only be described as "split" in all directions. She found she could not complete the third stage, so after pulling on the cord, which was torn right out, and getting away as much of the membranes as she could, she left

the case, and four hours afterwards had the audacity to call on me and tell me what had happened; and flatly refused to go back to the case when told to do so by me, saying that she was going out to spend the day with a friend, the lady president of the nursing club. I reported this case to the Supervisor of Midwives in this county. Unfortunately, this gentleman is a great friend of the lady president, and a reprimand only was obtained from the sanitary committee of the county council, the body which deals with such cases. I requested that I might appear before the committee, and place the facts before them; but the whole case was hushed up by the supervisor in a manner which speaks well for his ingenuity.

This practice of giving ergot in the early stages of labour is regularly followed by this nurse, and on several occasions I have been called in to complete the third stage of labour owing to a retained placenta from a semitonically contracted uterus.

I trust that this correspondence may lead to some inquiry into the conduct of the workings of these rural nursing associations, for some drastic legislation is sorely needed—I am, etc.

April 27th.

G. P.

Sir,—The kind, excellent women who would rush to their neighbours to nurse them with tenderness when in labour have indeed been crushed out by these young unmarried nurses who think themselves very clever and important about the use of antiseptics; but how many require the lysol for cleansing themselves rather than the patients? As one who has been at many beds of the sick poor and dying, and witnessed the dirty habits, hardness, unkindness, and flightiness of the nurses, I plead and ask for something to be done by the medical profession to condemn these associations. If only more ladies in the districts would do more acts of charity and interest themselves amongst the sick poor (not by trying to treat the cases for the doctor), but to see that they were cared for in the way of comforts and nourishment which the doctor orders, I feel far more good would be done in this way than all this so-called "nursing," which is not worthy of the name.—I am, etc.

A DEFENDER OF THE MEDICAL PROFESSION.

THE INTERMITTENT TREATMENT OF SYPHILIS.

Sir,—I have read with much interest your reply to "Enquirer" as to the treatment of syphilis, at page 1099. It is needless to say that the preference expressed for the 1-grain grey powder pill has given me lively satisfaction, coming as it does at the present juncture when several rivals are in the field. For most of your statements I have of course nothing but warm approval to express, but on one point I may beg to be allowed to put a question, and it is, I believe, a very important one. Why are interrupted courses recommended in preference to continuous ones?

It is suggested to give the constitution "periods of rest." Now I must contend that, with rare exceptions, if the course be well managed, there is not the slightest need for periods of rest. A two years course, begun at the earliest possible date and pursued without any intermission whatever, is, I feel convinced, the safest plan. The farmer is accustomed to give his grazing land intervals of rest by driving his flocks elsewhere for a time. His object is, however, to let the grass have a chance of growing. Do we not, in the treatment of early syphilis, effect much the same end in favour of the spirochaete by periods of "rest from mercury." I can think of no motive for intermitted courses other than the sportsmanlike instinct not to hit a man when he is down, whereas our object clearly should be to kill utterly.—I am, etc.

London, W.C., May 4th.

JONATHAN HUTCHINSON.

RESISTANCE TO PUERPERAL INFECTION.

Sir,—With reference to your leading article in the BRITISH MEDICAL JOURNAL of April 24th, commenting on the different views held by some of our leading obstetric physicians on the prevention of puerperal infection, a question I think worth asking is, Why is it that under the most adverse and dirty conditions of both bedclothes

and person, some women go through the puerperium with normal temperatures, whereas others not nearly so disadvantageously placed contract virulent sepsis, though all precautions have been taken? Is it not likely to be due to subnormal resisting powers of the individuals attacked? Would we not be likely to succeed in the stamping out of this scourge if we would combine with our efforts of asepsis efforts towards raising the opsonic indices of all our patients during the latter months of gestation, and trying to counteract the debilitating effects of prolonged labours?—I am, etc.,

Manchester, May 2nd.

MARTIN J. CHEVERS.

THE PATHOLOGY OF INSANITY.

Sir,—In your appreciative article on the Pathology of Insanity (p. 1014 of the BRITISH MEDICAL JOURNAL), and also in your leading article entitled "A Mental Hospital for London," you very properly, if I may venture to observe, recognize the credit due to the London County Council for its enlightened interest in the special investigation of insanity—a disablement which more than any other affects the welfare of the community, and which also, in regard to its proximate causation and prevention, still leaves accurate knowledge a desideratum.

It is hardly in accordance with such an appreciative criticism that the founder and originator of the pathological laboratory of the asylums of London should remain unnamed.

It is generally known in this country and acknowledged abroad that no individual occupying high public offices has done so much to encourage the modern study and investigation of mental diseases as Sir William Collins—not only as a medical man and a sanitarian in the best sense, but also as an administrator.

Alarmed by the increasing prevalence of insanity as demonstrated by statistics, sympathetic with the sad fact that the complaint itself precluded the sufferer from accurately complaining, and moved by an appreciation of the complexity and intricacy of the affected tissue, as also of the subtle chemical constitution of the underlying physical structure in cases of insanity, Sir William Collins, from the time he entered the London County Council in 1892, whole-heartedly associated himself with the project of establishing a scientific laboratory fully furnished for original investigation into the causes of insanity.

This laboratory—with its physical research room containing ophthalmoscopic, laryngoscopic, x-ray, and other electrical appliances; with its photographic studio containing photomicrographic apparatus; with its histological and pathological department containing a chemical and bacteriological equipment, with its spacious Museum and Library—was the outcome of great labour and careful inquiry. It was based upon information obtained through scientific experts in this country and abroad, special information from the Foreign Office through the various embassies, and from the Home Office through the Lunacy Commissioners being fully considered by Sir William Collins. How well the Director of the Laboratory has used his material is known to the world, and it would be an impertinence for me to refer further to it.

In the earlier days of neuropathology—less than twenty years ago—it was no small triumph to forecast the usefulness and value of this research work. It was no smaller triumph to convince lay colleagues in order to execute the scheme. The results which you have criticized reflect in an especial degree upon the statesmanlike qualities and upon the sympathetic zeal of a mind devoted alike to "alleviate the lot of the poor" and to stimulate "additions to natural knowledge."

If you will read the preface written by Sir William Collins to the first volume of the *Archives of Neurology*, you will, I know, readily admit the claims to public acknowledgement of so highly reputed and distinguished a member of our profession as are those of the founder of the London Asylums Pathological Laboratory.—I am, etc.,

Claybury, April 28th.

ROBERT JONES, M.D., F.R.C.P.

* * If Dr. Jones will read the illustrated article, published in the JOURNAL of February 18th, 1899, p. 420, in which we first brought the Pathological Laboratory of the London County Council under the notice of the profession, he will see that special mention was made of the share

taken by Sir William Collins in the foundation of the Laboratory. In our review of the first volume of the *Archives of Neurology*, which appeared in the *JOURNAL* of November 25th, 1899, p. 1483, reference was made to the fact that Sir William Collins had contributed a preface. Again, in our review of the second volume of the *Archives*, published in the *JOURNAL* of March 7th, 1903, p. 1555, we quoted from that preface. We have, therefore, already on several occasions done what Dr. Jones rather late in the day calls upon us to do. If the name of Sir William Collins was not mentioned in our review of the latest volume of the *Archives*, or in the leader entitled "A Mental Hospital for London," that was due, not to any wish to ignore the part which he played in establishing the Laboratory at Claybury, but to the fact that we were dealing with the work done at the Laboratory and with Dr. Maudsley's offer to the London County Council, with neither of which, as far as we are aware, was Sir William Collins concerned. The Athenians got tired of hearing Aristides called the Just. We hope that when Dr. Jones writes, "The results which you have criticized reflect in an especial degree upon the statesmanlike qualities and upon the sympathetic zeal of a mind devoted alike," etc., he said one of those things one would like to have expressed differently. We did not criticize the results, but simply tried to set them clearly before our readers. If Dr. Jones thinks that these results "reflect" in any way upon the statesman of whom he has come forward as the champion, that must be regarded as his opinion. It certainly is not ours.

URTICARIA.

SIR.—Heidenhain and others have shown that urticaria is due to poisons affecting the endothelial cells of the capillaries—lymphagocytes, he calls them—present in crayfish, mussels, etc. I should like to know what is the correct treatment in such cases. As several people may partake of the same dish and only perhaps one of them develop nettle rash, are we to suppose that an antilymphagogue is present in the blood or tissues of some people? and if so, what is this antilymphagogue? and would it be possible to separate it and use it as an antitoxin?

I had one patient who suffered most severely from nettle rash for some months, and no treatment seemed to mitigate it; there was no history of any poison. Are we to suppose that in her case the endothelial cells underwent some change and did not become normal for some months, or are we to suppose that some poison was retained in the system which continually acted upon the cells? Are we all liable to poisoning by lymphagogues? But, protected by the presence of an antilymphagogue, the product of, say, one of the ductless glands, there are, of course, several "internal secretions" the use of which is not exactly known. May this be one of the uses? The importance of these internal secretions probably cannot be overestimated; it may be that a deficiency in one or other of them may predispose an individual to tuberculosis or even cancer. It is impossible to keep up to date with all that is written on cancer or the like; but it might be worth while for those who are working on the subject and who have the material to study to hand, to ascertain whether the function of any particular organ is found impaired in association with cancer.—I am, etc.,

Leytonstone, April 23rd.

ARTHUR TODD WHITE.

ELECTRICITY IN INFANTILE PARALYSIS.

SIR,—Much has been written of late, both in this *JOURNAL* and elsewhere, as to the benefits to be derived from surgical measures in old-standing cases of infantile palsy. All who are interested in the subject cannot but welcome any fresh means whereby the ravages of this disease may be, to some extent, repaired. Unfortunately, however, contemporaneously with this advance, there has been a tendency to decry the well-established treatment by electricity in favour of graduated exercises; and this in cases in which the question of surgical treatment does not arise.

No one would be so foolish as to deny the value of medical gymnastics, but their field of application is strictly limited. They are, in common with massage, useful as an

adjunct to electrical treatment, but they can never take its place. The reasons are as follows:

(a) In many cases voluntary power is non-existent in the affected muscles.

(b) Where some control remains, even the mildest exercises cannot infrequently produce fatigue and aching.

(c) Infantile paralysis is primarily a disease of the cells of the anterior cornu and of their efferent nerves. Electric currents, especially those produced by the induction coil, have a specific effect in stimulating partially atrophied nerve centres into fresh activity, an effect which—at least so far as our present knowledge goes—it is impossible to produce by any other agency.

The good effects of faradic treatment on weakly muscles are almost too well known to need emphasizing; but it is true that other means, such as massage, may sometimes produce equal benefit. It must be remembered, however, that the function of the damaged cells is not only motor, but trophic; and it is in the stimulation of this latter power that electricity stands unrivalled. An arm or leg which for years has been blue and cold and shrunken takes on new life; its temperature rises and its colour improves. Nor is this all. In children who have not yet reached their full growth, the development is accelerated, so that the increase of relative shortening is checked, and the diseased limb ceases to lag behind its fellow.

Finally, we do well not to forget that the health of these subjects is usually bad and their vitality low. To treat the paralysis successfully without attending to the patient is scarcely possible; and there is no better means of raising the bodily tone than by general electrization in the form of baths.—I am, etc.,

F. HERNIMAN-JOHNSON, M.B., Ch.B. (Aberd.),

Bishop Auckland, April 19th.

(R.N. (ret.))

Universities and Colleges.

UNIVERSITY OF OXFORD.

Diploma in Ophthalmology.

CONGREGATION on May 4th approved a statute for a diploma in ophthalmology.

Examination for the M.Ch. Degree.

The examination for the degree of Master in Surgery will commence in the Medical Department of the Museum at 10 a.m. on Thursday, June 24th. Names must be sent in to the Assistant Registrar at the University Registry not later than 10.30 a.m. on Friday, June 4th. The statuatable fee (£5) and the required certificates must be given in at the same time.

Examination for the D.P.H.

The examination for the Diploma in Public Health will commence on Tuesday, November 16th, at the Museum. Both parts may be taken together at the same examination, or they may be taken at separate examinations; but no one will be deemed to have satisfied the examiners in Part II unless he has satisfied the examiners in the subjects of Part I. The fee for each part is £5. Names of candidates and fees must be sent in not later than 10.30 a.m. on Tuesday, October 26th, to the Assistant Registrar, from whom all particulars can be obtained.

UNIVERSITY OF CAMBRIDGE.

Degrees.

THE following degrees were conferred on April 29th:

M.D.—A. W. Wakefield, Trin.; S. Gooding, Joh.; E. E. Glynn, Cla.
W. F. Buckle, Govy. and Cai.; R. A. Clapham, Emu.
M.B., B.C.—M. W. B. Oliver, Trin.

B.C.—A. C. D. Firth, Trin.

Professor Woodhead has been reappointed Representative of the University on the Council of the Lister Institute of Preventive Medicine.

VICTORIA UNIVERSITY OF MANCHESTER.

The Students' Union.

THE Chancellor (Lord Morley) formally opened the new buildings of the Students' Union on April 30th. When first the Union began in 1861 it was little more than a debating society, using the college court room, but in 1893 it obtained the old house near the university, which has remained its head quarters until to-day, though for some time it has been much too small to meet the growing needs. The new buildings have cost about £23,000, which has all been raised except about £1,500. The university authorities provided the site and the whole cost of the refectory, and the late Mrs. J. Worthington gave funds for building the women's union. The men's premises have cost over £10,000, most of which has been raised by the students and old members of the university. The men's and women's portions are under the same roof but quite

separate. The buildings are of brick with stone facings, and shields carved with the coats of arms of families connected with the university are seen over doors and windows. Opening out from the entrance hall is a large reading room and some small rooms for various purposes, while a passage leads to the refectory, which will be used in common by men and women students and the teaching staff. A library, and a fine room for the debating society, occupy the first floor, while on the second floor is a billiard room. The women's portion has a drawing room with library and reading room, and small rooms for social purposes.

There was a crowded audience in the large debating-room to hear Lord Morley. Mr. Alfred Haworth, President of the Union, in welcoming Lord Morley, said that the Union formed not the least important part of the University. It was founded in 1861 by Mr. E. J. Broadfield, whom they were glad to have with them on the present occasion. The President raised considerable laughter by saying that he had been present on three occasions at least when the debating society had passed a resolution to mend or end the House of Lords. He took the opportunity to thank those who had contributed to the building funds, and especially the past students who had shown their loyalty to their *Alma Mater*.

Lord Morley said he would not spoil the occasion by what could be called an academic speech, nor would he open the great controversy touched on by Mr. Balfour and himself last year when they received degrees from the university as to whether literature or science were preferable; there might be preferences, but not exclusions. He then mentioned in a casual way one subject after another, lightly dismissing them all as too serious for the occasion, but incidentally he promised that later in the year he might have an opportunity of following up the subject of the rival claims of the old and the new universities.

Sir Frank Forbes Adams moved a vote of thanks to Lord Morley, which was supported by Miss McNicoll, Chairman of the Women's Union, and by Vice-Chancellor Hopkinson. When Lord Morley rose to respond he was received with a great burst of enthusiasm.

UNIVERSITY OF BIRMINGHAM.

The Ingleby Lecture.

The Ingleby Lecture will be delivered this year on May 27th by Sir Thomas Barlow, Bart., K.C.V.O., M.D., F.R.C.P., who has chosen for his subject "Raynaud's Disease and Erythromelalgia: A Summary and a Review."

Lectures on the History of Medicine.

A course of three lectures, commencing on May 6th will be given by Dr. David Fraser Harris, F.R.S.E., on "The History of Discovery of the Circulation," "The History of Knowledge of the Respiration," and "The History of Knowledge of the Nervous System."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary quarterly Comitia was held at the College on Thursday, April 29th. The President, Sir R. Douglas Powell, in the chair.

University of Geneva.

Dr. Pasteur, who was appointed to represent the College at the forthcoming 350th anniversary of the University of Geneva in July next, finding himself unable to attend, Dr. Habershon was appointed in his stead.

Membership.

The following gentlemen were admitted Members of the College: Clifford Beards, B.A., M.B.Oxon., L.R.C.P.; Edward Alfred Cockayne, M.B.Oxon.; Donald Elms Core, M.B.Vict.; William Griffith, M.B.Vict.; Frederick Gowland Hopkins, M.B.Lond., L.R.C.P.; Leonard George Joseph Mackey, M.D.Birm., L.R.C.P.; Percy Whittington Saunders, B.A., M.B.Toronto, L.R.C.P.; Henry Charles Gustavus Semon, M.A., M.B.Oxon., L.R.C.P.; Arthur Stanley Woodwork, M.B.Lond., L.R.C.P.

Licences.

The Licence of the College was granted to 91 gentlemen. The quarterly report of the Examiners for the Licence on the results of the January examinations was received.

Fellowship.

On the nomination of the Council, the following gentlemen were elected Fellows of the College: John Edward Squire, C.B., M.D.Lond.; Theodore Stacy Wilson, M.D.Édin.; Charles John Macalister, M.D.Édin.; George Harold Arl. Leveton Harris, M.P., M.B.Cantab.; Robert Oswald Noon, M.D.Oxon.; Clive Riviere, M.D.Lond.; Oliver Key Williamson, M.D.Cantab.; Francis Arthur Bainbridge, M.D.Cantab.; John Shields Fairbairn, M.B.Oxon.; Otto Fritz Frankau Grünbaum, M.D.Cantab.; Joseph Shaw Bolton, M.D.Lond.; Charles Bolton, M.D.Lond.; Llewellyn Carotacus Powell Phillips, M.D.Cantab.

Communications.

The following communications were received: 1. From the Board of Trade, March 26th, on Beri-Beri, in continuation of previous correspondence in 1908. This was referred to the Standing Committee on Beri-Beri.

2. From Dr. Raymond Crawford asking permission to photograph the portraits of Sir Charles Scarborough and Sir Edmund King, and a similar request from Mr. Leveton Harris, M.P., with regard to those of Dr. Cadogan and Sir George Baker, in possession of the College. Both requests were granted subject to the usual conditions.

University of London.

On the nomination of the Council, Sir William Allchin, M.D., was elected a Representative of the College on the Senate of the University of London for a term of four years from May 11th next, in place of Dr. Pye-Smith, who had resigned.

Admission of Women to the Examinations of the College.

The following by-law was enacted for the second time: "Women shall be eligible for admission as Licentiates and Members of the College and for the grant of a diploma in Public Health on the same terms and conditions as men, and, so far as is necessary to give effect to this by-law, words in the by-laws and regulations importing the masculine gender shall include females, and all proper alterations shall be made in the forms of the letters, testimonial, and the licence granted by the College. *Provided always* that women shall not be eligible for election as Fellows of the College, or be entitled to take any part in the government, management, or proceedings of the College."

University of Sheffield.

Dr. Herringham was elected a Representative of the College on the Court of Governors of the University of Sheffield, in place of Dr. F. T. Roberts, who did not desire re-election.

Reports.

The following reports were received: 1. From the Committee of Management, dated March 22nd, recommending:

(a) That a revised syllabus of the examination for the diploma in Public Health be adopted.

(b) That the Grammar School, Cheltenham, be added to the list of institutions recognized by the Examining Board in England for instruction in Chemistry and Physics.

(c) That Merchant Taylors' School, which is already recognized for instruction in Chemistry and Physics, be also recognized for instruction in Biology.

These recommendations were adopted.

Library.

Books and other publications presented to the library during the past quarter were received, and thanks returned to the donors.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

ELECTION OF EXAMINERS.

At a meeting of the Council held on Tuesday, May 4th, the following examiners were elected for the ensuing year:

Court "A."

For Conjoint Licence, Diploma in Public Health, and Preliminary.

Anatomy.—A. Fraser, F.R.C.S.; B. C. A. Windle, B.S. Univ.Dub.

Surgery.—C. A. K. Ball, F.R.C.S.; A. Blaney, F.R.C.S.; F. Conway-Dwyer, F.R.C.S.; R. J. Harvey, F.R.C.S.

Physiology and Histology.—D. J. Coffey, B.S., R.U.I.; E. L'Estrange Ledwich, L.R.C.S.

Pathology and Bacteriology.—A. H. White, L.R.C.S. Midwifery and Gynaecology.—F. W. Kidd, L.R.C.S.

Biology.—J. J. Burgess, F.R.C.S.

Ophthalmology.—A. H. Benson, F.R.C.S.; H. C. Mooney; H. B. Cunningham, F.R.C.S.

Sanitary Law and Vital Statistics.—M. J. Russell, F.R.C.S., D.P.H.

Engineering and Architecture.—J. H. Fergusson, F.R.C.G.S., D.P.H.

Languages.—W. Kennedy, M.A., F.T.C.D.

Mathematics, Physics, Dictation, and English Essay.—J. W. Tristram, M.A.Dub.Univ.

Court "B."

Fellowship, Licence in Surgery (for registered practitioners), Licence in Midwifery (for registered practitioners), and Licence in Dental Surgery.

Anatomy.—A. Fraser, F.R.C.S.; E. P. McLoughlin, B.Ch.

Surgery.—C. A. K. Ball, F.R.C.S.; A. Blaney, F.R.C.S.; F. Conway-Dwyer, F.R.C.S.; L. G. Gunn, F.R.C.S.

Physiology and Histology.—D. J. Coffey, B.S., R.U.I.; E. L'Estrange Ledwich, L.R.C.S.

Pathology and Bacteriology.—R. J. Rowlett, M.D.Dub.Univ.; A. H. White, L.R.C.S.

Midwifery and Gynaecology.—F. W. Kidd, L.R.C.S.

Chemistry and Physics.—E. Lapper, F.R.C.P.; R. J. Montgomery, F.R.C.S.

Dental Surgery and Pathology.—G. M. P. Murray, F.R.C.S.; W. G. Story, L.D.S.

Mechanical Dentistry.—D. L. Rogers, L.D.S.; E. L. Sheridan, L.D.S.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examinations indicated:

FIRST PROFESSIONAL.—H. Shaw, A. M. Robertson, W. Laird, M. McCloskey, J. T. Kelly.

SECOND PROFESSIONAL.—W. Millerick, C. S. Owen, A. L. Edwards, J. Macrae, J. A. Hutchinson, F. F. Keravalla, H. R. Macnab, C. Hunter, A. Carnana.

THIRD PROFESSIONAL.—F. Williams, J. Blackburn, P. Valesh, G. A. O'Discol, J. W. Robertson, D. R. Gazdar, W. Browne, E. D. Shroff, F. P. Quirk, N. B. Mehta, W. M. Thomson, R. C. Fuller, S. N. S. Aizangar.

FINAL.—D. G. Lindsay, N. B. Mehta, J. McCall, V. G. Gokhale, H. E. Swan, Isabel Pulteney.

Public Health

AND

POOR LAW MEDICAL SERVICES.

LATEST PHASE OF THE CASTLEFORD DISPUTE. WHAT is described in the *Yorkshire Evening Post* of May 1st as "an acrimonious discussion" took place at the last meeting of the Pontefract Board of Guardians. It had reference to the question of the remuneration of the district medical officer for the Castleford District of the Pontefract Union. It is now evident that the Pontefract guardians are prepared to do the right thing, but in the wrong way. More than twelve months ago the two medical officers of the Castleford District represented to the guardians that the work was most inadequately remunerated, and asked for an increase of payment. The guardians not only declined to grant this, but practically forced upon Drs. G. B. Hillman and W. Kemp the resignation of their appointments.

On March 7th, last year, we published in these columns an article, *Seven Farthings for State Medical Service*, giving surprising details of the parsimony and niggardliness of the Pontefract Guardians. No self-respecting medical man could have been expected to continue to discharge the duties under the circumstances clearly placed before the guardians. By a misuse of its power the board dismissed Drs. Hillman and Kemp from the posts of public vaccinator simply because they declined to continue to serve the State in another department at such a miserable apology for remuneration. The warning published in this JOURNAL and the unanimous attitude of the profession in the immediate district resulted in the guardians finding it impossible to secure more than one person willing to undertake the duties. To accommodate this applicant the two districts were combined, although quite recently the guardians had held that it was in the public interest that two districts with separate officers should exist. Within a few months the guardians capitulated and admitted the validity of the only point at issue by raising the salary 33 per cent. This concession, as we predicted on October 3rd, 1908, did not end the troubles experienced by the guardians. The *Castleford Express*, April 23rd, in reporting the proceedings of the Pontefract Board of Guardians, publishes the following letter addressed to the board by Dr. Hall, whose disregard of the warnings and facts of the case deprives him of all title to any sympathy on the part of his professional brethren:

Will you kindly bring before the board my application for some substantial remuneration for my loss during the past year? The amount received is £419. In the advertisement the amount was stated to be £220; the increase of salary made it total £240. Medicines as supplied by Mr. Wainwright cost £57 1s., as per his bill. Surgical dressings, appliances, etc., cost £20. Dressings and instruments for vaccinations cost £10. Moving expenses £20. Amounts paid to other doctors for work done in my unavoidable absence, costs for assistance and loss in private practice. Consequently when these amounts are deducted there is very little left for my services. I will feel very grateful to the board if they will generously consider my request, as the only stimulus I have had since coming to Castleford is that the board have looked with kindness, sympathy and pity on me, through my troubled course here in Castleford. I would again assure the board of my earnest desire to carry out my duties allotted to me by them conscientiously and with as little trouble to them as possible. I feel I cannot close this letter without commenting on the numerous complaints made against me, and against me in the board's report, in each case. I will now and by again thanking the board for their past consideration.

This letter appears to have roused the board to a sense of what the chairman is stated to have considered to be "a matter of honour." Drs. Hillman and Kemp, in their manly and straightforward application over a year ago, found no such response. The letter from Dr. Hall provides a complete vindication of the action of the previous officers, and demonstrates to the point of absolute proof the statements upon which the application for an increase of remuneration was based. The combined remuneration was £60 per annum. It was contended that this involved an actual loss. Dr. Hall's letter shows that the cost of drugs, surgical appliances, dressings, etc., amounted in the year to £67 1s., or £7 more than the combined salaries concerning which the dispute arose. Powerless to controvert these facts, we should have thought that a board, with any regard for its honour, would desire to seek to make some reparation for the injury and persecution inflicted on the two former officers. That stage, however, has not yet been reached. They prefer to reward Dr. Hall for his demonstration of the folly and unreasonableness of their action by voting him a bonus or allowance of £25. If Dr. Hall has performed the duties with credit to himself and satisfaction to the board and the public, he may be entitled to more remuneration than he

has received; but as he entered upon the contract with the guardians knowing the circumstances, he seems to have little real ground for complaint for having made a bad bargain. The question of the legality of the "allowance" of £25 will surely engage the attention of the Local Government Board or the auditor, and it would not be surprising to find that members of the board who voted this consolation fee may have to pay for their sense of honour out of their own pockets. A surcharge might have the effect of causing the guardians to see the wisdom of doing what they ought to have done in the first instance, in which case many acrimonious discussions and wasted hours would have been avoided. Peace with honour is by no means secured by the latest phase of the Castleford Dispute. The guardians are beaten on the only point in dispute, and the simplest way to avoid further loss of dignity would be a frank and free admission that a mistake has been made.

LONDON MILK.

IN the course of a general discussion on the annual estimates at the London County Council on May 4th several questions relating to public health were raised. Dr. Beaton moved a reduction of the Parliamentary Committee's estimate in order to urge that when the Council's General Powers Bill comes back from the Lords the House of Commons should be asked to reinsert the clauses relating to pure milk. Dr. Beaton thought that with the introduction of so complex a Budget there would be little likelihood of Mr. Burns being able to fulfil his promise to introduce general legislation on the subject of milk supply. The Chairman of the Committee, however, preferred to rely on the Government pledge.

The Public Health Committee was subjected to criticism from both sides when it brought forward its estimates. The Progressives wanted to know why there had been a delay of eleven months in putting into force Part IV of the London County Council General Powers Act, 1907, relating to milk inspection, and to receive the reply that preliminary arrangements took some time. Then Mr. Easton, from the other side, condemned milk inspection, and said the whole of the money spent on it was wasted. Dr. Beaton in reply said that with the limited powers it had the committee were doing excellent work in preventing tuberculous milk from coming into London. Next came Mr. Thompson, the late Vice-Chairman of the Council, who moved the omission from the estimates of an item of £350 for the expenditure on the investigation of the Lister Institute into the causes of death from acute infection other than tuberculosis of guinea-pigs. Uniformed members laughed at this item, but Mr. Gilbert Johnstone (Chairman of the Committee) soon explained its significance. He said that of 1,025 samples examined by the Lister Institute, material from 167 samples caused the death from some acute infection, the nature of which was not ascertained, of guinea-pigs into which the material had been subcutaneously injected. Obviously this was a matter for careful investigation, for it might be that there was some worse danger than tuberculosis in the milk. The Lister Institute was prepared to continue the investigation for another twelve months, and the Public Health Committee felt that so large a percentage of deaths from an unknown cause was a matter which should be explained as soon as possible. The amendment was lost.

WATERY MILK.

IN a case decided recently in France a milk seller was fined 300 francs (£12)—a very considerable penalty as compared with those usually imposed at petty sessions in England—for selling milk which he proved to be deficient in solids and fat, but which was said by the defendant to be the genuine product of his cows without added water. The deficiency was held by the court to be due to feeding the cows upon watery food or giving them an excessive quantity of water to drink. The writer in *La Semaine Médicale* (April 28th, 1909), where the case is reported, quotes the passage from the *Georgics* of Virgil: *Ipse manu salassae fent praesepit agens*, "Hinc et amant *Ilvius magis, et mater ubera tendunt*," to show that it is no new discovery, and that the Latin peasants knew as well as the modern milkman how to increase the quantity of liquid given by their cows. The court rejected the defence, holding that if cows are fed on food which has this effect it is a dishonest proceeding, and the result is as much an adulteration of the milk as if the water had been taken direct from the pump. We do not know whether such a statement has ever been given in this country, but it seems to be sound in principle.

THE CONTROL OF DIPHTHERIA.

E. F.—IN the BRITISH MEDICAL JOURNAL for January 23rd, 1909, p. 219, a short account will be found of a discussion at the Society of Medical Officers of Health upon the scientific control of diphtheria. A fuller report is published in the *Public Health* for March, 1909, p. 139. It is often extremely difficult to get rid of the Klebs-Loeffler bacillus from the throat or nasal passages of contact cases, more especially when there are no clinical signs of the disease. We believe it is usual for medical officers of health to expect to receive notification certificates of persons who are found to be harbouring Klebs-Loeffler bacilli.

Obituary.

GERALD FRANCIS YEO, M.D., F.R.S.,

EMERITUS PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON.

We much regret to announce the death of Dr. G. F. Yeo at the age of 64 years. Gerald Yeo, as he was usually known, was the second son of the late Henry Yeo, J.P., of Howth, Dublin, and was born in the year 1845. He received his early education at Dunganon School, Tyrone, and subsequently he went to Trinity College, Dublin, where he graduated as M.B. in 1867 and M.D. in 1871. In the latter year he was awarded the Gold Medal of the Pathological Society of Dublin for his essay on the diseases of the kidney. He started practice in Dublin, and became a teacher of anatomy in the university of that city; a year or two later he travelled and pursued further studies in the Universities of Paris, Berlin, and Vienna, and in 1874 was appointed to the Chair of Physiology at King's College, London, where he succeeded the late Professor Rutherford who had received a similar appointment in Edinburgh University. At first he combined his work at King's College with that of Assistant Surgeon at King's College Hospital, but he soon relinquished the latter post, and devoted himself entirely to the duties of his Chair, which he held for sixteen years, resigning it in 1890. After his resignation the Council of King's College bestowed upon him the title of Emeritus Professor.

Gerald Yeo was an enthusiastic worker, and fully maintained the high traditions of his Chair. During his Professorship he held a good many examinerships, and produced his well-known *Manual of Physiology*, which became a popular students' textbook, passing through six editions in less than ten years. He was not a voluminous writer of original papers, but all that he published was carefully thought out, and rested on the firm foundation of sound work. He is best known for his work performed in conjunction with Dr. Ferrier on the subject of cerebral localization in monkeys, a research which may truly be described as epoch-making. His other published papers related to the bile, the blood pigment, tissue respiration in the heart, muscle sounds, the graphic record of muscular contractions, and other subjects, the enumeration of which shows his versatility. Those interested in the antivivisection controversy will remember the struggle in which he and Dr. Ferrier were involved by an abortive attempt to prosecute them for their experiments on monkeys.

Among other positions that Professor Yeo held we may mention that he was Vice-President of the Section of Anatomy and Physiology at the meeting of the British Medical Association held at Worcester in 1892; he was one of the Secretaries (the late Professor Roy being the other) of the Physiological Section of the International Medical Congress held in London in 1891, a post for which he was particularly suited not only on account of his capacity for hard work, but also because of his fluency in foreign tongues. The great success which attended this Section is to be very largely traced to his efforts.

He is, perhaps, best known outside his Professorship as the first Secretary of the Physiological Society. In its early days this society was mainly a mutual protection society against the intrigues of the antivivisectionists, but it gradually developed into what it is now, a learned society in the more usual acceptance of that term. Yeo was one of the founders of this society, and threw himself into its work with characteristic energy. He held the office of Secretary for a period of fifteen years. When he resigned the post in 1890 the society marked their esteem for himself and for his work which had always been carried through with unflinching tact, by the presentation to him of a beautiful silver tea service. It is to Yeo in conjunction with one of his greatest friends, Professor Kronecker of Berne, that we owe the inception of the international physiological congresses which have met every three years since the first, which was held at Bale in 1891.

But Gerald Yeo had hobbies outside of his science, and dearly loved the country and country pursuits; he was a keen gardener, fisherman, and yachtsman, and many of his physiological colleagues will remember their visits to him at his country home in Fowey, where he was able to let them share with him his love of the sea. After he

retired from King's College, he withdrew to Totnes, where he devoted himself almost entirely to country life, coming up to town only on rare occasions for meetings of scientific societies. He was elected a Fellow of the Royal Society in 1889.

He was twice married; first to Charlotte, the only daughter of Mr. J. Kitchen, in 1873, and secondly to Augusta Frances, second daughter of Mr. Edward Hunt of Thomastown, co. Kilkenny. He leaves a widow and several sons to mourn his loss.

A bare record of the career of Gerald Yeo such as the foregoing lines supply conveys little or nothing of the character and charm of his personality. Like most Irishmen, he was a fluent speaker and an attractive lecturer; he was a delightful companion, and the stories with which he garnished his conversation, and which were related in inimitable brogue, will long be remembered by his friends. He brimmed over with good nature and generosity, and with all this was a keen observer and judge of human nature, and all his actions were actuated with sound common sense. The world is the poorer by his loss, and keen regret will be felt by all who knew him, and sincere sympathy extended to those nearest and dearest to him.

JAMES LIMONT, M.A., M.B., M.R.C.P.

FORMERLY PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

On May 1st James Limont, M.A., B.Sc., M.B. Edin., M.R.C.P., late of Newcastle upon-Tyne, died in Edinburgh. For the last three years Dr. Limont had been in failing health, and two years ago he resigned his appointment at the Royal Victoria Infirmary and left Newcastle to regain his health if possible. A son of the late Rev. William Limont, Presbyterian minister at Alnwick, Dr. Limont was born in this quiet Northumberland town on April 9th, 1856. After a distinguished career in Edinburgh University, and after holding residential appointments in the Royal Maternity and Simpson Memorial Hospitals, and the post of Senior Demonstrator of Anatomy at the Minto House School of Medicine, Dr. Limont proceeded to Glasgow, where for a period he was House-Surgeon and House-Physician to the Royal Infirmary. Twenty-five years ago he became Senior House-Surgeon and House-Physician to the Newcastle Infirmary. In 1885 he was appointed Physician to that institution, an office the duties of which he discharged with great ability and much acceptance to the committee and patients. On the establishment of a department for skin diseases, Dr. Limont, who had been specially preparing himself for the post, was unanimously appointed Physician-in-Charge, in addition to his other duties. As a consultant, his opinion was frequently sought, while as a clinical teacher he stood out prominently among his colleagues, his method of instruction being much appreciated by the students. In the early years of his professional life he showed considerable interest in the meetings of the North of England Branch of the British Medical Association, and at the local banquets was in much request, for he sang with great taste and effectiveness. A well-known golfer, the name of Milton under which he played was held in high esteem. By the death of Dr. James Limont Newcastle and the North of England have been deprived of the services of a highly-trained and most capable physician. Much sympathy is felt for Mrs. Limont and her family of one son and four daughters.

ROBERT HARRISON WILSON, M.D. DUN.,

GATESHEAD.

A LITTLE over a fortnight ago the grave closed over the cremated remains of the late Dr. R. H. Wilson of Gateshead. Dr. Wilson had reached the age of 82, and, although for several years he had suffered from recurrent attacks of bronchitis and asthma, which obliged him five years ago to relinquish practice, he was at the time of his death in fairly good health. He had gone for his customary walk that morning, but during the course of the day was seized with an attack of heart failure to which he succumbed. Until within the last few years Dr. Wilson was one of the busiest of medical practitioners. He simply lived in his brougham, working from early morning till late

evening. It has fallen to few medical men to enjoy and to retain the confidence of their patients of all classes as Dr. Wilson did.

Dr. Wilson first came into public notice during the third and last epidemic of cholera in 1853, when his efforts to check the ravages of the disease were unremitting; in the following year, when there occurred the "great fire" in Gateshead and Newcastle, no man, it is said, worked harder or gave of his time so ungrudgingly to the wounded as Dr. Wilson. Besides Dr. Gibb, of Newcastle, who was house-surgeon in the Newcastle Infirmary at this date, there are few of his medical compeers left in the North of England, but there are still many of a younger generation who remember the many acts of kindness they received at the hands of Dr. Wilson, and by them his death is much regretted. Although in all senses of the word a most successful and esteemed practitioner, Dr. Wilson had experienced considerable grief and sorrow through family bereavement in the death of two of his sons—one in a mine accident—and the death of a married daughter. A widow, three sons, and three daughters survive him. The body was cremated at Darlington.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

CIRCULARS TO PATIENTS.

J. M. McL.—In sending out circulars care must be taken that they reach only those who are bona-fide patients of the practice. If they are sent out with the quarterly or half-yearly accounts there can be no question of the bona-fides.

ADVERTISING BY CLUBS.

GEN. PRAC.—We do not think there is any objection to our correspondent accepting the appointment, provided that no further advertising of the club takes place.

Medico-Legal.

DENTAL MECHANICS.

W. F. G.—There cannot, we think, be any objection to a registered medical man employing a dental mechanic.

PROFITS DURING INTRODUCTION.

QUERENS asks: In the case of a short introduction (six weeks) of a successor to a practice (not preliminary partnership), is the purchaser usually paid as assistant, or does he receive a share of the receipts; if so, what ratio of them?

. This is a matter usually settled in the agreement of sale.

During a short introduction all the profits might be shared equally between the vendor and purchaser, or one of them might pay all the expenses, take the profits, and make an allowance to the other.

The Services.

ROYAL ARMY MEDICAL CORPS (TERRITORIAL).

LECTURES ON ARMY SANITATION.

A COURSE of six lectures on army sanitation will be given in the Department of Military Hygiene of the Royal Institute of Public Health, 37, Russell Square, W.C., on Wednesdays at 6 p.m. On May 12th Surgeon-General Evatt, C.B., will deal with the officer and his duties in respect of the well-being of the soldier under his command; on May 19th Lieutenant-Colonel R. H. Pirrh will lecture on practical sanitation in camps; and on May 26th Lieutenant-Colonel C. H. Melville will speak on the essential principles of sanitation in the field. On June 2nd Lieutenant-Colonel R. J. S. Simpson, C.M.G., will deal with hospital work in war; on June 9th Professor R. T. Hewlett will lecture on the bacteriology of diseases common to armies in the field, and on June 16th the course will be brought to a close by a lecture by Lieutenant-Colonel C. S. Monkton Copeman, M.D., F.R.S., on inoculation methods for the prevention of diseases to which the soldier is liable. All officers of the Territorial Force are invited to attend, and further particulars can be obtained on application to the Honorary Secretary, Mr. James Cantlie, M.B.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.

The offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Aitiology, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National):—

2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2630, Gerrard, BRITISH MEDICAL ASSOCIATION.

2634, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

✉ Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

✉ We would request correspondents who desire to ask questions in this column not to make use of such signatures as "A Member," "A Member B.M.A.," "Enquirer," and so on. By attention to this request much confusion would be avoided. Correspondents are asked to write upon one side of the paper only.

C. W. W. desires to hear of a quiet seaside place suitable for a young family, and where accommodation could be obtained for it at a moderate price, where facilities for bathing, golf, tennis, and excursions are available, and which is within two days' motoring of London.

HARD WATER AND ARTERIO-SCLEROSIS.

CALCIUM asks: Are there grounds for believing that the persistent drinking of hard water will lead eventually to arterial degeneration from presence of excess of calcium salts in the economy?

DISPENSING AND NON-DISPENSING PRACTITIONERS.

COLONIAL, now resident in England, is considering the conversion of a non-dispensing practice into a dispensing one. He would be glad of some idea of: (1) The salary required by a lady dispenser and bookkeeper; (2) what increase in the income may be expected in a practice of £1,000 per annum, mainly upper-class patients.

TAPEWORM IN NURSING MOTHERS.

HELMINTH asks for counsel as to the treatment of a case of tapeworm in a patient nursing a healthy infant aged 4 months. Segments of the worm have been passed at intervals ever since the third month of pregnancy, their diameter being $\frac{1}{8}$ in. But for the fact that the segments are seen, there is little or no evidence, subjective or objective, of helminthiasis. The treatment prescribed, if any, should be such as will not interfere either with lactation or with the health of the infant.

INCOME TAX.

URTICARIA subscribes to a friendly society, in consideration of which he has recently received a weekly money allowance during illness. He asks whether the amount so received must be included in his statement of income for assessment to income tax.

. So far as we are aware, the point has never been brought before the courts, and the Income Tax Acts do not specifically refer to it. In our judgement, however, sickness pay received from a friendly society is not assessable to income tax, and therefore we consider that our correspondent is not bound to include the amount received in his statement of income.

ANSWERS.

H. W. D.—Of the instruments mentioned, Oliver's latest compressed air haemomanometer is probably that best adapted for accurate observations.

M. S.—*Public Health*, the official journal of the Society of Medical Officers of Health, is published monthly, and deals with current public health matters. *The Sanitary Record* and *The Medical Officer* are each published weekly. The latter is styled "A Journal for Medical Men in the Government and Municipal Services," and a great deal of its space is devoted to sanitary affairs.

JOHN P. HAIG'S "CURE" FOR GOITRE.

Some information with regard to Haig's goitre cure is given in a paper by J. Kochs in the *Apotheker-Zeitung*, abstracted in the *Pharmaceutical Journal* for April 14th, 1906, p. 447. According to this the "cure" comprises: Powders, consisting of sodium bicarbonate, coloured pale red; ointment, consisting of a sodium soap with yellow soft paraffin; pastilles, consisting of sodium bicarbonate, aloes, and a little oil of caraway; pastilles, consisting of extract of hydrastis.

BOOKS ON CHRISTIAN SCIENCE.

The following might suit our correspondents' purpose: *The Faith and Works of Christian Science*, by the author of *Conscious Medici*, just published by Macmillan and Co.; *The Truth and Error of Christian Science*, by M. Carta Sturge (Moral Science Tripos, Cambridge), with an introduction by the Rev. H. S. Holland, M.A., Canon of St. Paul's, published by John Murray, Albemarle Street, London, 1903; *Christian Science: The Faith and its Founder*, by Lyman P. Powell, published by G. P. Putnam's Sons, New York and London. The Knickerbocker Press, 1907; *Christian Science, Medicine, and Occultism*, by Albert Moll, M.D., Berlin, only authorized translation from the German, by F. J. Rebman, published by Rebman, Limited, 129, Shaftesbury Avenue, W.C., 1902; *Faith-Healing and Christian Science*, by Alice Fielding, published by Duckworth and Co., 3, Henrietta Street, W.C., 1899; *Christian Science*, an Exposition of Mrs. Eddy's Wonderful Discoveries, including its Legal Aspects, by William A. Farrington, published by E. B. Treat and Co., 241-243, West Twenty-third Street, New York, 1900. But perhaps, after all, Mrs. Eddy's own book, *Science and Healing*, to the intelligent reader supplies the most convincing refutation of her doctrines.

LETTERS, NOTES, ETC.

DR. SIDNEY GRAHAM (Watchet, Somerset) desires on behalf of Dr. Sharpe and himself to thank those friends who supported the candidature of the son of Dr. John Sharpe, late of Watchet, but now of Berrow, Burnham, Somerset, for admission to the Royal Masonic Institution for Boys. The boy was placed thirty-fifth out of forty-nine vacancies.

THE TREATMENT OF ANKYLOSTOMIASIS.

DR. W. ROBERTSON (Durban, Natal) writes to say that some years ago he drew attention in the *South African Medical Record* to the utility of sulphur in bilharziosis. He has since tried it in ankylostomiasis with equally good effect. He suggests that possibly the ingestion of sulphur kills the parasites by increasing the percentage of H_2S in the intestines.

APPENDICITIS AND RHEUMATISM.

DR. ROBERT T. MORRIS (New York) writes: In the letter recently sent to the *BRITISH MEDICAL JOURNAL*, in which I commented upon the large proportion of cases of appendicitis of rheumatic origin in the practice of Dr. Alexander Haig, I had no intention of calling into question the accuracy of observation of such a renowned teacher of the profession, whose position is too responsible to allow of his making loose statements. It was simply a question of the relative proportion of cases of each one of the four kinds of appendicitis that would find their way to the offices of men engaged in different fields of practice. Dr. Haig would naturally see more cases of rheumatic origin. In my own practice at least half of the cases of appendicitis are apparently of mechanical origin. In the practice of the gastro-enterologist, on the other hand, it is probable that much more than half of the number of cases of appendicitis are of the fibroid degeneration type, and not infective or rheumatic. Fibroid degeneration appendicitis, occurring in the course of normal involution of the appendix, perhaps forms the largest class, and seem to present the most common single cause for "intestinal dyspepsia." One of my colleagues recently said that the reason why these appendices are often called "Morris's appendices" is because no one else can find them. As a matter of fact, almost any one can find them if he will make deep pressure over the site of the right group of lumbar sympathetic ganglia, about 1½ in. to the right of the navel. If there is hypersensitiveness at this point, and not at corresponding point at the left of the navel, the rest of the testimony bearing upon the point will have a good basis in evidence. Such appendices on removal will be found to be undergoing fibroid degeneration in the course of their involution. On microscopic examination they will be found to contain much hyperplastic connective tissue, and persisting nerve filaments will be surrounded by such groups of new cells that one can easily enough read the histiolytics as meaning that contraction of the connective tissue is producing an irritative lesion, sufficient in degree to excite the intimate ganglia of the bowel wall (Auerbach's plexus and Meissner's plexus), and to lead to perversion of intestinal function, with the symptoms of "intestinal

dyspepsia." Such appendices will be found more often in the practice of the gastro-enterologist. Rheumatic appendices will be found more commonly in the office of Dr. Haig. Appendices which are the site of acute infective invasion, with the mechanical feature dominant in the cause and effect relationship, will be found more often in the hands of the surgeon. We thus have a shield with more than one side, and one may perhaps be careful about generalizations when he speaks of appendicitis as a diagnostic entity, and without qualification as to kind.

FOUL BREATH.

THIS disagreeable infirmity is associated with a large number of pathological conditions, and in any given case the particular lesion must be sought out and effectively treated. In a paper read to the West London Medical Society last year (*West London Medical Journal*, April, 1908) Dr. Andrew Leslie summarized them very completely, and drew attention to one or two points not generally known. He pointed out that free discharges of the nasal contents may not occur, although there may be no real obstruction, owing to desiccation of the mucous membrane in roomy or wide nostrils, and this may be the result of too energetic treatment of the turbinate bones by the galvano-cautery, or be due to constitutional causes, such as anaemia. Chronic epistaxis in plethoric persons may be attended with fetor, as the blood adheres to the mucous membrane, soon becomes septic, and creates an unpleasant odour. But while it is undoubtedly the case that foul breath is commonly associated with definite pathological conditions, it is also true that any one of them may be present without giving rise to fetid breath, and, further, that the foul odour may be present apart from any pronounced disease. The fetor is not the direct consequence of the inflammatory condition or growth or deformity, but of local infection by one or more of the many feter-producing organisms, usually belonging to the groups of coliform, mesentericus, or putrefactive bacteria, which are only imperfectly known and are well deserving of special study. One of the difficulties in writing about them is that there are not only many names for the same organism, but it is not always certain that two writers mean an identical organism when they call it by the same name.

THE PREFRONTAL VEIN AS A MEANS OF IDENTIFICATION.

In the *Gazzetta degli Ospedali* of April 16th, Professor Tamassia, of Padua, who has recently been made Senator of Italy, suggests, as a subsidiary aid to identification, recording the disposition of the prefrontal vein or veins. If a vertical line is drawn from the glabella upwards the relation of the vein or veins to his line can be graphically recorded and form a means of identification. The vein may run strictly parallel to the vertical line, may form an angle with it, may cross it, may run in duplicate on either side or as two parallel veins on one side. In addition to the direction of the vein, note is made of its fullness, tortuosity, etc. The author has made many observations and believes that the variations in the disposition of the frontal vein are sufficiently marked to make this a useful addition to our means of personal identification.

INSURANCE APPLICATIONS

THE way in which application forms for insurance are filled up are often most amusing in their enlightening. As illustrations we take from the *Medical Examiner* of New York the following statements said to have been made in applications in the United States:

Mother died in infancy.

An uncle died of cancer on his mother's side.

Father went to bed feeling well, and the next morning woke up dead.

Grandfather died suddenly at the age of 103. Up to this time he bid fair to reach a ripe old age.

Applicant does not know anything about maternal posterity, except that they died at an advanced age.

Applicant does not know cause of mother's death, but states that she fully recovered from her last illness.

Applicant has never been fatally sick.

Father died suddenly; nothing serious.

Applicant's brother, who was an infant, died when he was a mere child.

Grandfather died from gun-shot wound, caused by an arrow, shot by an Indian.

Applicant's paternal parents died when he was a child.

Mother's last illness was caused from chronic rheumatism, but she was cured before death.

All remittances by Post Office Order must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

An Address

ON

ACUTE RHEUMATISM, ITS ALLIES
AND ITS COUNTERFEITS.*BY F. DE HAVILLAND HALL, M.D., F.R.C.P.,
SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL.

It is to be hoped that the time is coming when we shall be as successful in stamping out acute rheumatism as we have been in the case of malaria and typhus fever in this country, and as it would seem we are about to be in tuberculosis. It is difficult to estimate the amount of misery that would be prevented could we but limit the spread of acute rheumatism. Under 30 years of age I should estimate that four-fifths of all the cases of valvular disease of the heart are due to acute rheumatism, and I suppose that there is no more pitiable sight in a hospital ward than a patient gradually dying from heart failure resulting from the endocarditis of acute rheumatism.

I would lay especial stress on the importance of recognizing that in children slight pains, commonly described as growing pains, an attack of tonsillitis or erythema may be the only manifestation of the rheumatic diathesis, and yet quite sufficient to set up endocarditis with all its lamentable sequelae.

The whole subject of rheumatic fever has been much clarified since its probable microbic origin has been acknowledged, and there is much evidence in favour of the *Diplococcus rheumaticus* described by Drs. Payne and Poynton as being the specific organism. Just as the discovery of the tubercle bacillus cleared up many doubts and difficulties which formerly existed in tuberculous cases, so the recognition of the rheumatic organism will enable us to form a truer conception of its nature, and we shall be able to exclude many conditions which were in the past embraced under the head of rheumatism, but which we now have every reason to believe are of a widely different pathology. Time was when the joint lesions of acute rheumatism were thought to be characteristic, but we now know that they may be simulated by pyaemic conditions—as in a case to which I shall direct your attention later on—and by gonorrhoeal rheumatism, to say nothing of gouty arthritis. In children, moreover, as I have just mentioned, the disease may run its course with hardly any, if any, joint mischief, the heart bearing almost the whole brunt of the disease. We must, therefore, regard rheumatic fever as a general disease with localization in the heart and joints, and not a local disease of the joints with symptomatic fever.

It is quite unnecessary for me to enter into a description of the symptoms of an attack of acute rheumatism. To all present I am sure that these symptoms are only too familiar, as rheumatic fever is unfortunately very common in our damp climate. I would, however, like to make a few remarks on some of the chief complications of this disease. Among these, affections of the heart take the first place. It is difficult to overestimate the frequency with which the heart is affected in cases of rheumatic fever and the evil effect this has upon the life-history of the individual. Even as far back as the time of Sir Thomas Watson it was recognized that the chance of the heart being involved during an attack of acute rheumatism, which is very great before puberty, diminishes as life advances. He writes:†

I have known only two persons pass through acute rheumatism with an untouched heart prior to the age of puberty, and in these two I am by no means certain that the articular disease was genuine rheumatism.

Life Assurance.

The damage done to the individual is becoming more and more appreciated by assurance companies. For my part, I believe that the companies would save money if they declined to accept any applicants who had suffered from an attack of rheumatic fever. In my small book on

The Medical Examination for Life Assurance? I have laid down the following rules:—*Insurance life is dangerous to the patient in bed two or three weeks and to incapacitate him from his occupation for six or seven weeks, would require the addition of an equivalent to seven years at the age of 30, and three years must have elapsed since the attack.* If there has been more than one attack, the life would not be assurable until at least ten years after the last attack. An applicant with a rheumatic history had better not be accepted under the age of 25 years.

Increasing experience in life assurance has in no way tended to diminish my fear of acute rheumatism. Indeed, I am inclined to add a rider to the above rules and to suggest that cases with a rheumatic history should only be taken for an early endowment policy.

According to Sir William Churchill's statistics, 80.55 per cent. of the cases under 10 years of age had signs of old or recent endocarditis. The percentage gradually dropped to 34.64 in those over 40, with an average percentage of 57.50—that is, his figures show conclusively that more than half the cases of acute rheumatism have endocarditis—a truly formidable indictment against the disease, and a warning not to neglect the earliest indications of acute rheumatism.

Endocarditis of rheumatic origin may come on during fetal life, and be the cause of some of the varieties of congenital heart disease. Indeed, a fetal endocardial murmur has been recognized before labour. At the Lumsiean Lecture on March 25th, 1909, Dr. Norman Moore exhibited the hearts of a woman and her fetus, both showing signs of endocarditis. The mother had acute rheumatism.

It is more difficult to detect pericarditis than endocarditis, so that one need not be astonished to find that Sir William Churchill's statistics show that only 14.87 per cent. of men and 9.95 per cent. of women with rheumatic fever suffered from pericarditis. My late colleague, Dr. Sturges, insisted that in many cases we have to deal with a pancarditis—that is, that a myocarditis exists in connexion with the pericarditis and endocarditis, or even independently of either. It is probably to this myocarditis that we owe the sudden deaths from acute dilatation of the heart which occasionally take place during the course of acute rheumatism. The possibility of the myocardium being affected should be borne in mind during convalescence from acute rheumatism, and the patient should be kept in the recumbent position for at least two or three weeks after the temperature has become normal and the pulse quiet. Indeed, I think that to be on the safe side four to six weeks would not be too long. Unfortunately, with the demand on hospital beds, this counsel of perfection can rarely be carried out in hospitals, but more might be done to impress upon private patients the necessity of prolonged rest in the recumbent position after an attack of acute rheumatism. If this could be done much less would be seen of valvular disease of the heart.

While on the subject of pericarditis I would like to draw attention to a physical sign present at a very early stage of the disease, which I do not think has received sufficient attention—I mean cantering action of the heart; and by cantering action I understand the presence of three sounds in the cardiac rhythm. Two of the sounds being, of course, the first and second sound of the heart, and the third being due to the commencing pericardial friction, before it has sufficiently developed to give rise to the so-and-so friction rub.

Pleurisy.

Pleurisy is another complication which I have seen from time to time during the course of acute rheumatism. The fact that it chiefly affects the left pleural cavity would seem to indicate that it arises in connexion with some cardiac infection, and, indeed, that has been my experience. I have usually seen a pleural effusion in patients who have suffered also from pericarditis. It has been stated that 10 per cent. of all cases of acute rheumatism get pleurisy, but this seems to me too high a percentage. Possibly more cases would be detected if all patients were carefully examined, but the pain attending these examinations in rheumatic subjects is often a bar to the necessary investigation.

Tonsillitis.

I think that it is now generally agreed that pharyngitis is a very common complication of acute rheumatism;

[2524]

* A paper read before the Croydon Division of the British Medical Association.

indeed, it has been stated that sore throat is present in 80 per cent. of all cases of rheumatic fever. Owing, however, to the attention of the patient being concentrated on his arthritic symptoms, he will often omit to mention spontaneously the fact that his throat is sore, and this possibly accounts for the discrepancy in the percentage of cases reported by different authorities. The throat is usually affected a day or two before the onset of the articular pain, but occasionally there is no complaint of throat trouble until after the rheumatic affection has fully declared itself.

It has been suggested that the tonsils are the chief portals for the entrance of the poison of rheumatic fever, and there is much to be said in favour of this view. When sore throat is the chief feature of a rheumatic attack cardiac lesions are seldom seen, though cases do occur in which endocarditis and pericarditis are met with even when articular pains are entirely absent. Such a case I reported at the meeting of the British Medical Association in 1889, in the discussion on "Tonsillitis and its Relations to Rheumatism." The patient was a girl of 8, with a sharp attack of lacunar tonsillitis. As her medical attendant informed me before I saw the child, she seemed much worse than the throat condition would account for. On examining the heart I found pericardial friction and an apical murmur. It may be argued that the cardiac symptoms were not due to the poison of rheumatism, but arose from the absorption of a septic material from the tonsil, and that the symptoms were really of septic origin and not rheumatic.

Until we have some certain method of recognizing the *Diplococcus rheumaticus*, or whatever germ be the cause of rheumatism—and I most emphatically believe that it is a disease of microbic origin—we shall always be confronted with the difficulty of distinguishing between anomalous cases of acute rheumatism and septicaemia. In rheumatic sore throat the margin of the soft palate, the tonsils, and the posterior wall of the pharynx will be found of a deeper red colour than normal and somewhat swollen. In the more severe cases there may be some oedema of the mucous membrane and especially of the uvula.

The symptoms due to this pharyngitis are sometimes so slight that, as I have already stated, the patient will omit to mention them unless questioned on the subject, but in the more severe forms dysphagia, pain extending up to the ears, and difficulty in speaking occur.

As regards the different varieties of tonsillitis, the lacunar is the form which is most commonly associated with rheumatism.

Chorea.

Chorea has long been regarded as a manifestation of the rheumatic state. Indeed, Dr. Bright, of Guy's Hospital, as early as the beginning of the last century, clearly recognized the relationship, but it has required constant iteration to keep this fact before the profession. It has always been a matter of wonder to me how some able physicians could disregard the very strong evidence in favour of the connexion. My late colleague, Dr. Sturges, a man of a singularly well-balanced mind, did not believe in any intimate connexion between the two diseases, though he was candid enough to write as follows: "Cases in which chorea arises in the course of rheumatism are so striking and so similar that notwithstanding the comparative rarity of the conjunction it is difficult to resist the conclusion that the one affection actually gives rise to the other."⁴ When this conjunction takes place, in the great majority of instances in my experience the joint trouble has preceded the chorea, which came on either while the rheumatism was abating or during convalescence. If the chorea should make its appearance in the acute stage of the rheumatic affection, the patient is in a lamentable plight, the constant choreic movement aggravating the pain of the original disease.

As regards the way in which chorea is produced by the rheumatic poison, an analogy may be drawn between this disease and diphtheritic paralysis. We have very good ground for believing that the toxins produced by the Klebs-Loeffler bacillus give rise to the paralysis by acting on the peripheral nerves; we may therefore assume that chorea is probably caused by the toxins of the rheumatic bacillus affecting the motor areas in the brain. This is a much more reasonable suggestion than that chorea is brought about by a shower of minute emboli being carried

to the motor centres, which was the opinion at one time held.

The Skin Affections of Rheumatism.

Many cases illustrating the connexion between erythema multiforme and rheumatism have been placed on record. The varieties most frequently met with in rheumatic subjects are those known as erythema papulatum and erythema marginatum or circinatum.

The eruption of erythema papulatum consists of spots varying in size from a pin's head to that of a sixpenny piece, of irregularly rounded outline and slightly elevated. The colour is of bluish-pink; a slight hæmorrhage may take place into the spots, so that when they fade they leave behind them a faint mark resembling a bruise. The eruption appears in crops.

Erythema marginatum occurs in circles of various size up to the diameter of several inches. The circle is formed by a slightly raised pink ring with a central area of a livid hue.

Erythema nodosum is far less commonly met with in the course of acute rheumatism than the varieties just mentioned. With regard to the relation of erythema nodosum to rheumatism, Stephen Mackenzie came to the following conclusions: "(1) That erythema nodosum is frequently associated with definitely rheumatic symptoms—for example, arthritis, sour sweats, sore throats, etc. (2) That heart disease (endocarditis) may arise during an attack of erythema nodosum, both in cases in which arthritis is present and in cases in which there is no affection of the joints. (3) That these conclusions justify the inference that erythema nodosum is frequently, if not generally, an expression of rheumatism even when no other definitely rheumatic symptoms are present."⁵

Urticaria may also be one of the earliest symptoms of an attack of rheumatic fever. Hence the appearance of any of the eruptions which I have just mentioned, after exposure to cold and damp, with some concomitant feverishness, should suggest the possibility that it is the precursor of an attack of acute rheumatism.

Angio-neurotic oedema is sometimes met with in rheumatic cases. This occurs as puffiness of the face, hand, or other part of the body. Pain and itching are almost absent; at the outset there may be a little pricking when the patches begin to swell. Whether it is more than a mere coincidence in the rheumatic attack has yet to be settled. A scarlatiniform rash has been described; this is probably scarlet fever with joint symptoms.

Desquamation has occasionally been noticed in rheumatic cases. Sudamina and miliaria rubra occur when there is profuse sweating. Herpes labialis and herpes zoster have been described as complications of acute rheumatism.

"Peliosis rheumatica" is the term applied to an eruption of small bright-red spots, the size of a lentil, situated chiefly upon the legs below the knees, which gradually change in colour to brown or yellow. It is accompanied by pain in some of the joints, and valvular disease of the heart has resulted from it. It is a rare disease, and its exact relation to rheumatism is uncertain. Both purpura simplex and purpura hæmorrhagica have been met with in rheumatic cases.

Subcutaneous Nodules.

In Hillier's book on *Diseases of Children*, published in 1868, an account is given of a case in which subcutaneous nodules occurred, and various Continental writers have described cases in which nodules have been observed. It is, however, to Dr. Barlow (now Sir Thomas) and Dr. Warner that is due the credit of pointing out their frequency and importance as clinical evidence of the rheumatic diathesis. The paper presented by these authors to the International Medical Congress in 1881 gives an admirable account of the whole subject, and a *précis* of the 27 cases upon which the paper is based. Indeed, I may safely assert that nothing of importance on the subject has been added to their original observations. It was one of the best pieces of clinical work that was presented to the Congress.

These nodules vary in size from that of a mustard seed to that of an almond. They are, as their name implies, strictly subcutaneous, and are not connected with the skin. They are free from redness and pain, and only very slightly tender.

They most commonly occur about the joints, especially the malleoli, the back of the elbows, and the margins of the patellae. They are also met with on the pinna of the ear, the temporal ridge, the superior curved line of the occiput, the spinous processes of the vertebrae, the spine of the scapula, the crista ili and the extensor tendons of the foot and hand. These nodules are fairly common in children, but rare in adults. As they do not give rise to pain they require to be looked for—or should I not rather say to be felt for?—as they may sometimes be more easily recognized by the touch than by the sight.

They occur discrete or in clusters and in number from one up to fifty or more. Sometimes only a single crop appears; in other cases two or three crops occur. They last from a few days to four or five months. Individual nodules greatly increased in size while under observation, and on the other hand, some subsided and then grew again. They disappear after the rheumatic attack is over. None of the nodules became bony, or infiltrated with urate of soda, or suppurated. Dr. Barlow and Dr. Warner describe the growths as "round or oval semitransparent fibrous bodies, in appearance like boiled sago grains." Microscopically they are found to be composed of "wavy strands of fibrous tissue, with caudate, spindle-shaped, nucleated cells and abundant vessels."

As regards their anatomical site, they have been found attached to tendons, to the deep fasciae, and to the pericranium. They have been found in the pericardium after death. These nodules are without doubt evidences of rheumatism; they are usually associated with the severer forms of this disease, and the more numerous and the larger they are the worse is the prognosis. In all the cases recorded by Dr. Barlow and Dr. Warner some morbid condition of the heart was present, and eight out of the twenty-seven patients died from the result of the heart disease, a clear indication of the grave prognosis afforded by the presence of these nodules. Dr. Cheadle's experience is even more unfavourable than this. He regards the eruption of large nodules as almost equivalent to a sentence of death. "They mean persistent cardiac disease, generally uncontrollable, and marching almost infallibly to a fatal ending." I think that I have now said enough to prove the great diagnostic and prognostic value of subcutaneous nodules.

Dr. A. E. Garrod* has pointed out that nodules closely resembling those met with in young rheumatic patients are occasionally seen in sufferers from rheumatoid arthritis with no obvious rheumatic antecedents, and who have reached a period of life at which true rheumatic nodules are extremely rare.

A condition which seems to be intermediate between the erythematous and subcutaneous nodules has been described by Dr. Cayley⁹ under the title of Multiple Cutaneous Fibrous Nodules Associated with Rheumatism. Dr. Cayley pointed out that in his case "the nodules had all the characters of rheumatic fibrous nodules, except that they were situated in the skin as well as in the fasciae." It has been suggested that circumscribed scleroderma has a possible etiological relation to rheumatism.¹⁰

Diagnosis from Pyaemia.

One of the difficulties which occurs in the diagnosis of rheumatic fever is to distinguish it from that variety of pyaemia which comes on without any very obvious source of suppuration. A case of this kind was admitted under my care into the Westminster Hospital some years ago.

The patient was a man aged 21, who complained of joint pains and sweating. Eventually the pain became confined to the right shoulder. I had some doubt as to the correctness of the diagnosis of acute rheumatism, as the temperature chart was unlike that met with in this disease, but resembled the temperature chart of suppuration or malaria. It was not, however, until the day before the patient's death that I recognized the error in the diagnosis. At the necropsy one or two points of a sanio-purulent fluid were found in the right pleural cavity, septic abscesses in the base of the left lung, pus in the right shoulder-joint, and diffuse intermuscular abscess in the left hand and lower end of arm.

Now that we recognize that acute rheumatism should be classed among the diseases due to microbic infection, it can easily be understood that there may be considerable difficulty at times in distinguishing it from other forms of infection. In reference to this point, Fagge and Pye-Smith¹¹ write: "Sometimes, in spite of all care, diagnosis

is impossible till after death, and difficult even then." They mention a case which occurred to Dr. Moxon¹² in Guy's Hospital.

A patient was admitted who had nine days before been attacked with headache, sickness, and rigors, and in whom these symptoms were followed by profuse sweating and by pains in the joints. Salicylic acid was prescribed, but the temperature rose and delirium set in, so that cold baths were employed on several occasions. The question whether the disease could be pyaemia was formally discussed and negatively in favour of the diagnosis of acute rheumatism. He made no complaint of the thigh, as being more painful than other parts, when he was there moved into or out of the bath. Yet at the autopsy not only was there osteitis of the lower part of the shaft of the right femur and of the adjacent epiphysis, but the bone was denuded of its periosteum, and there was a large collection of pus beneath the muscles. There was also suppuration about the shoulder and pyaemic abscesses in the lungs and heart.

Dr. Moxon's case very closely resembles mine, and I felt that I was in very good company when I made the erroneous diagnosis. The moral I would venture to draw from these cases is that in cases of acute rheumatism presenting any unusual features, the possibility of pyaemia should be borne in mind, and careful search should be made for the source of suppuration. Especial attention should be paid to the state of the ears, as one of the most frequent primary lesions is caries of the petrous bone.

An important distinction between acute rheumatism and pyaemia is stated to be that in rheumatism the pain and swelling fly about, leaving one joint, and after a few hours attacking another. Now this is just what happened in my case, and it was this that determined me to adhere to my diagnosis of acute rheumatism. Failure to respond to salicylates should awaken suspicion that the case is not one of rheumatism.

Pyaemia most commonly affects boys and young men, and, as a rule, the skin is dry instead of sweating as in rheumatism; the joints are more frequently hot and of a deeper red colour.

Rigors are uncommon at the onset of acute rheumatism, their occurrence, therefore, should suggest pyaemia rather than rheumatism.

Diagnosis from Influenza.

The onset of influenza is sometimes very difficult to differentiate from that of acute rheumatism, more especially if the former be accompanied by arthritis. There is, however, little or no effusion into the joints in the influenzal cases, but the ends of the joints are tender and enlarged and the seat of most of the pain. In some of the cases the joint affections proved to be rheumatoid arthritis, and others developed into various forms of neuritis. It used to be held that influenza did not lead to valvular disease, but extended experience has shown that this is not true, as cases of endocarditis and pericarditis of influenzal origin have been reported. On the other hand, simple dilatation and various cardiac neuroses, such as bradycardia, tachycardia, and angina, are only too commonly the result of this disease.

It will be found that the salicylates usually relieve the pain and pyrexia of influenzal cases, but the after-history of these cases is different from that of rheumatic arthritis.

Infective Endocarditis.

Infective endocarditis may present joint affections, sweats, and purpuric rashes, and was formerly regarded as rheumatic in origin. In fact, the transition in the symptoms from septic cases to ordinary rheumatic endocarditis is marked by insensible gradations. Still, it is recognized that most malignant cases are produced by streptococci, diplococci, or staphylococci, though the presence of the lesions of former rheumatic endocarditis favours the outbreak of the disease.

Antitoxin Arthritis.

The arthritis which occasionally follows the use of antitoxin is certainly non-rheumatic. As regards the joint affections of scarlatina, at one time they were regarded as nothing more or less than a rheumatic manifestation. Recent investigation, however, has shown that these cases may be grouped under four heads:

1. A simple synovitis, which occurs about the sixth day, and is six times more common than all the rest put together.

2. Septic.
3. Tuberculous.
4. True rheumatism.

The last only occurs during a late state of convalescence, and is always subacute. The early type with which it is usually confounded never recurs, is not accompanied by sweating, does not fly from joint to joint, rarely if ever affects the heart or shows any other rheumatic sequelae, and is specially apt to develop in the tendons on the back of the hand rather than in the wrist-joint. The true rheumatic type is rarer even than the purulent forms, and appears in quite an insignificant proportion of cases.

Gonorrhoea.

The affection of the joints occurring as a result of gonorrhoeal infection is sometimes confounded with rheumatic arthritis. Gonorrhoeal synovitis is usually the result of a gonorrhoeal urethritis, but Mr. Clement Lucas¹² has recorded 23 cases of gonococcus joint disease in infants secondary to purulent ophthalmia, and a few years ago I admitted into the Westminster Hospital a nurse with arthritis due to purulent ophthalmia contracted by infection from an infant she was nursing. Gonorrhoeal arthritis of great intensity may occur in a newly married woman from an old gleet in the husband. I saw such a case in consultation a few years ago, and I had great difficulty in quieting the suspicions of the patient's mother, who was very insistent in knowing what was the cause of her daughter's shoulder and elbow being affected.

Gonorrhoeal arthritis usually comes on in early adult life—that is, more than half the cases occur between 20 and 30. When a patient has once suffered from gonorrhoeal arthritis a recurrence may occur as the result of passing a bougie, exposure to wet and cold, and excessive sexual intercourse.

Now that it is generally recognized that gonorrhoea is something over and above a mere affection of the urethra, we need a term to cover all the complications which may occur as a result of gonorrhoeal infection. I would suggest "gonorrhoeaemia"; and, just as we speak of pyaemia and pyaemic conditions, so we might talk of gonorrhoeaemia and gonorrhoeic states.

The symptoms of gonorrhoeal arthritis may come on at any period during the course of a gonorrhoea, most commonly between one week and three months. Generally the discharge has degenerated into a slight gleet, or even apparently disappeared, or there may be only the evidence of a stricture to excite suspicion. At the onset the patient is feverish, and suffers from malaise and anorexia. The tongue is furred. The patient is restless and depressed; sleep is interfered with by the pain. The pyrexia is almost always moderate, and in some cases the temperature remains about normal. Hyperpyrexia does not occur. Unlike ordinary acute rheumatism, there is little tendency, even in young subjects, for the heart to be affected, though some cases of malignant endocarditis due to the gonococcus have been recorded.

The inflammation is usually the lower extremities, the joints of the upper extremities being comparatively rarely attacked. The knee is the joint pre-eminently liable to attack. The plantar fascia is very frequently affected. The pains are worse at night, and are of an aching, grinding character. The lesion seems to affect the synovial membrane and ligaments of the joints. Any of the joints may become affected, and Mr. Brodhurst records a case in which finally ankylosis of every joint occurred. The temporo-maxillary joint is not infrequently attacked.

The joints of the fingers are very seldom attacked, a point of distinction from subacute cases of osteo-arthritis in young subjects. Each joint which becomes affected suffers for many days or even weeks, and there is not the rapid metastasis from joint to joint as occurs in rheumatic fever. Physical signs are well marked—that is, the joints are much swollen, both from intra-articular effusion and from exudation around. A very characteristic symptom of gonorrhoeal arthritis is the implication of the fibrous structures, especially of the loins, the plantar and palmar fascia, the tendo Achillis, and the sheaths of the nerves—for example, the sciatic. The muscles or their aponeuroses appear to suffer, so that the patient may complain of universal pain.

A peculiar form of inflammation of the eye frequently accompanies gonorrhoeal arthritis. Usually first one eye, then the other is attacked. There is injection of the small radiating vessels of the sclerotic which surround the cornea, that is, a scleritis, sometimes accompanied by iritis and catarrhal ophthalmia. As regards the diagnosis of the disease the presence of a discharge is obviously not sufficient to establish the point, for a man suffering from gonorrhoea may be attacked with rheumatic fever or gout. The chronicity of the disease, the implication of the fascia and other fibrous structures, the failure of salicylates to give relief, the moderate amount of pyrexia, the absence of cardiac complications and the presence of ophthalmia will usually suffice to determine the diagnosis. In doubtful cases a bougie should be passed in order to detect any stricture that may be present.

A gentleman aged 33 was sent to me on account of a painful and swollen knee, which was considered to be either gouty or rheumatic, but treatment directed to these conditions failed to give relief. It then occurred to me to inquire into the state of his urethra. The patient was found to have a stricture, the outcome of gonorrhoea contracted fifteen years previously. As soon as this had been thoroughly treated the patient lost his joint trouble, and has remained free from it.

Pneumococcal Arthritis.

Just as at one time gonorrhoea was regarded simply as a purulent inflammation of the urethral mucous membrane, so pneumonia was considered to be solely an inflammation of the lung substance. But even before the discovery of the pneumococcus it began to be realized that pneumonia was not infrequently associated with conditions that could only be explained on the ground of infection. Since Weichselbaum and Fraenkel in 1886 demonstrated the presence of the diplococcus in most cases of lobar pneumonia, we now know that the infection of pneumonia may be very widespread. As, for example, pneumococcal empyema, pneumococcal inflammation of the anterior mediastinum, of the meninges of the brain, of joints, and most important of all, the pneumococcus appears to be the most frequent of the micro-organisms giving rise to malignant endocarditis. On the present occasion, however, I must limit my remarks to pneumococcal arthritis. The cases of this disease hitherto reported have been few in number. I have only seen one myself, and that was in a child. On going over the *Transactions of the Clinical Society*—that storehouse of cases of unusual nature—I can find mention of only one case of pneumococcal arthritis.¹⁴

It is to be noted that in almost all the cases the arthritis followed the onset of the pneumonia at intervals varying from a few days to a fortnight. Therefore, if a patient suffering from, or recently convalescent from, pneumonia has any arthritic symptoms, the probability of this being due to pneumococcal infections should be borne in mind. In cases which occur independently of pneumonia the diagnosis can only be made by a bacteriological examination, though in a case reported by Mr. Barnard,¹⁵ where the knee-joint was opened, "the cavity of the joint was full of clots, which so closely resembled those seen in pneumococcal empyemata that a diagnosis of pneumococcal arthritis was at once made." This was confirmed by bacteriological examination.

The disease is one attended with a very high mortality. Of 31 cases collected and analysed by Dr. Cave,¹⁶ 23 died and 8 recovered. As a rule it affects adults or persons of advanced years, and males more frequently than females. The arthritis is commoner in the upper extremity than the lower, and in only about one-third of the cases was there a multiple joint affection. There is a very great difference in the clinical picture presented by these cases. In the mildest form there may only be slight pain and swelling limited to a single joint, whereas in the gravest cases there may be intense inflammation and distension of the joint and oedema of adjacent parts, going on to destruction of the ligaments and cartilages.

I do not pretend that I have by any means exhausted all the conditions which may simulate acute rheumatism. For instance, I have said nothing about gouty arthritis or rheumatoid arthritis; but I think that I have brought forward quite sufficient material to give rise to a good discussion, and it is very often the case that there is much more to be learned from the discussion than from the paper which opened the debate. I trust that this may be

the case on the present occasion, as I am only too conscious how sketchy my paper has been.

An Address

ON THE

DIAGNOSIS AND TREATMENT OF MORBID CONDITIONS OF THE PLEURA.

DELIVERED AT A JOINT MEETING OF THE BURNLEY DIVISION OF THE BRITISH MEDICAL ASSOCIATION AND THE BURNLEY MEDICO-ETHICAL SOCIETY.

By T. R. BRADSHAW, B.A., M.D., F.R.C.P.,

PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY.

It is impossible in the time at my disposal to discuss adequately the morbid conditions of the pleura, and rather than touch lightly on them all I will pass over some in silence, so as to be able to deal more fully with the others.

INDICATIONS FOR PARACENTESIS IN PLEURAL EFFUSION.

If I were asked to state in a sentence the indications for paracentesis in pleural effusion, I should say that every effusion that was big enough to diagnose was big enough to tap. This would be with the obvious reservation that effusions apparently small and unattended by any special local or constitutional disturbance should be left for a reasonable time in the hope that they may undergo spontaneous absorption. When the physical signs point to a large effusion, or when the symptoms, such as dyspnoea, indicate serious embarrassment of the heart or lungs, the operation should be performed without delay. But the persistence of signs of a small effusion is no less an indication for paracentesis, as may be seen from various considerations. In the first place, the extent of the physical signs is not always proportionate to the size of the effusion, which may be much greater than it appears to be. In the second place, until we see some of the fluid, we can never be certain as to its nature, whether serous, purulent, or hydatid; and thirdly, the prolonged presence of a small collection of serous effusion in the pleura is not to be looked on with indifference. Apart from the mechanical compression which it exerts on the lung, if we accept the teaching of Sir A. E. Wright and his school, we must believe that a tuberculous effusion having a lower tuberculo-opsone index than the other fluids of the body favours the existence of the bacilli in the parts which it bathes, and so ought to be got rid of as speedily as possible.

THE PERFORMANCE OF PARACENTESIS.

Having decided that paracentesis is to be performed, we should select a trocar and cannula of sufficient calibre to allow pus to flow through it. I employ the medium sized cannula supplied with Potain's pneumatic aspirator. I find Potain's pneumatic aspirator the most convenient for general use, but good results may be had with a simple tube acting as a siphon. The practice of making a preliminary exploration with a syringe and a fine needle is superfluous and undesirable. If fluid is found, the practitioner proceeds to employ the aspirator, and so two punctures are inflicted where one would have sufficed. If the result is negative the operator is in doubt whether the small needle was not blocked. The accidental puncture of the lung with a clean needle is not followed by any serious consequences. Certain points need to be especially attended to. The apparatus must be tested with water each time it is employed. The trocar and cannula must be introduced far enough to

make it certain that the pleura has been reached, the flow must be slow, and not more than 50 oz. should be withdrawn at the first operation. The remainder will probably undergo absorption; if it does not, it is not a serious matter to repeat the operation. It is well to tell the patient or his friends that you have not taken it all away.

MALIGNANT DISEASE.

The presence of blood in such amount as to give a red colour to the fluid is not uncommon, and is of no special significance, but a brownish or chocolate colour due to altered blood suggests the possibility of the existence of malignant disease. Sometimes the character of the cellular elements may also suggest the same condition. Malignant disease of the pleura or of the lung in such a position as to cause signs associated with the pleura is, however, such a rare event in the experience of any one individual practitioner that it is difficult to construct a clinical type for the disease. In general I should say that we ought to suspect the possibility of malignant disease in any case of pleurisy which, as regards its signs, symptoms, and progress, does not conform to the types with which we are familiar. Signs of pressure on structures not usually involved in pleural effusion, or of pressure not relieved by the removal of the fluid, strongly suggest a new growth. In one case there was oedema in the mammary region, enlarged axillary glands, distension of one jugular vein, and a slightly brassy cough. The trocar was felt to enter a hard mass. In another case there was paralysis of one vocal cord. In a woman lately under my care one of the earliest circumstances to arouse suspicion was finding that the effusion was of the colour of strong tea, and it was found to contain epithelial cells. Hard glands were present in the neck and axilla, and there was distension of the jugular veins on both sides. In another case there was nothing to suggest malignant disease until the pleura was opened for what seemed to be an ordinary empyema. It was then found that the pus lay in a cavity in a conical mass of new growth which extended for a considerable distance into the lung. In some cases one remains in doubt up to the very last whether one is dealing with malignant disease or tubercle, and even at the *post-mortem* examination a skilled pathologist may be unable to distinguish between them until a careful microscopic examination has been made. This actually happened in the following case:

A medical practitioner, aged 57, had pneumonia of the right lung in 1902, and made a good recovery. On June 8th, 1904, he consulted me with a large pleural effusion on the left side, the dullness reaching up to the clavicle, and the heart being pushed over to the right side. During the following three and a half months he was aspirated eight or nine times. Latterly the effusion was blood-stained, and in the fluid made little or no difference in the physical signs, and there was evidently a solid mass in the lung or pleura. During this time he was almost constantly in bed, complained of pain in the stomach, often severe, and got thin and weak. Tubercle bacilli were looked for in the sputum, but none were found. The temperature was moderately raised. The liver was enlarged. Towards the close there was dysphagia and severe dyspnoea, and a pericardial rub was heard. I could not make up my mind between a diagnosis of tubercle and of malignant disease, though I inclined to the former. He sank gradually, and died of asthenia on September 24th.

At the necropsy the naked-eye appearances led to the belief that the case was one of malignant disease. The right lung was normal, but the left lung was collapsed, the pleura being from $\frac{1}{2}$ to 1 in. thick. The mediastinal glands contained yellowish masses, and there were nodules in the pericardium. Microscopically bacilli were found in the left pleura and in one of the glands, and miliary tubercles in the collapsed lung.

HAEMORRHAGIC EFFUSION.

A remarkable condition, of which I have seen two instances during the last eighteen months, is the presence in the pleura, without any obvious cause, of an effusion consisting of almost pure blood. I am inclined to think this may be dependent on some constitutional condition, allied to the haemorrhagic diathesis or the purpuric state, as seems to have been the case in the following instance:

A railway inspector, aged 57, fell against a fender and fractured one or two ribs on March 8th, 1908, and was treated as an out-patient at the Royal Infirmary. I did not see him at that time, but I was informed that no effusion was observed until about March 18th, when extensive dullness was suspected and a needle inserted. No fluid, however, was found. On March 27th—three weeks after the accident—exploration was again

performed, and 27 oz. of nearly pure blood were removed. This was repeated three times during the succeeding seventeen days, 107 oz. of practically pure blood being withdrawn altogether. It might be said that this was simply a case of hæmorrhage from a ruptured intercostal vessel, but the assistant physician, who first saw the case in my absence, is positive that there was no effusion of any kind there at that time. Further, it was evident that fresh blood was poured out after the earlier tapings. Now, there are two points—one in the past history, the other in the subsequent development of the case—which I think throw light on the cause of the hæmorrhagic effusion. The first is that on seven years before he brought up a large quantity of blood, and was told he had broken a blood-vessel; the other is that on June 15th last year he was again admitted to the infirmary, this time with painful anasarca in the lower extremities accompanied by a persistent recurring purpuric eruption.

To my mind it is reasonable to conclude that the bleeding seven years before, the hæmorrhagic effusion, and the purpuric eruption shortly after it had all a common origin. In the other case, a gentleman wintering in Egypt, the most probable cause was thought to be the rupture of some pleural adhesions.

EMPYEMA.

Passing to the consideration of purulent effusion into the pleura (empyema), I maintain that there are no signs or symptoms by which we can with any approach to confidence distinguish it from serous effusion until some of the fluid has been removed for inspection.

Hectic fever is common enough in cases of serous effusion, as might be expected from the frequent co-existence of tubercle, and cases of empyema are generally attended by only a moderate rise of temperature, rarely above 102°, and generally less. No doubt a leucocytosis, if proved by a competent observer to be present, will be a point in favour of suppuration, but it is seldom of practical application for diagnosis except in hospital.

The diagnosis of empyema being, then, only established on finding pus flow into the aspirator, we have to consider how we shall deal with the case, first at the moment, and secondly with a view to permanent recovery. Many of these cases are suffering from urgent distress from dyspnoea and toxæmia, and are in need of immediate relief, and my practice is to continue the extraction and remove a considerable quantity of pus, perhaps a pint. By this means the urgent symptoms are at once relieved for a time, the temperature becomes normal, and the patient will probably have a good night. We thus gain time to make our arrangements for performing the greater operation under the most favourable conditions, and to get the consent of the patient or his friends. After many years' consideration of the subject, I have come to the conclusion that there is only one line of treatment to be adopted in every case of empyema, and that is the establishing free drainage by incising the pleura and introducing a good size drainage tube. I know that authorities allege that cases of empyema in which the only organism present is the pneumococcus may recover after a simple aspiration, and a few cases are recorded in various works in which such recovery has taken place. At one time it was my ambition to try to get cases of empyema well by aspiration alone, but I never succeeded; they all had to come to a free incision: and when one saw the great masses of lymph which sometimes presented in the wound it was not surprising that the attempt to evacuate the pleura through a cannula had failed.

Finally, the results of free incision on the condition of the lung and the general health of the individual are so excellent, that I doubt whether a cure by aspiration would be worth aiming at even if there were any reasonable probability of its being attained.

The dread of a free incision into the pleura was largely the outcome of theoretical considerations. It was supposed that as soon as air was admitted freely to the surface of the lung there would be nothing to counteract the elastic contractility of the organ, which would remain ever after in a state of collapse. I confess that it is not altogether easy to understand the full expansion commonly met with after the operation for empyema, amounting in some cases apparently to a *restitutio ad integrum*, but there is one important consideration that is apt to be overlooked—namely, that at every forcible expiratory effort, whether coughing or singing, or loud speaking, the collapsed lung is fully inflated by air driven out of the sound lung.

The belief that permanent collapse of the lung, more or less complete, is to be expected to follow the free admission of air into the pleura has led to the expenditure of no small amount of ingenuity in the vain and pernicious attempt to drain an empyema in such a manner as to allow the pus to escape, while preventing or restricting the entrance of the air. The usual result

of such proceedings is that the drainage is not free, that septic organisms gain entrance to the pleura, that the discharge becomes offensive, and that after much useless suffering and delay resort has to be had to a free incision. Many of you may think that at this time of day it is like flogging a dead horse to labour this point; but unfortunately I have good reason to believe that the old fear of a free opening is by no means extinct, and that futile attempts to limit the access of air by valvular

Fig. 1.—R. D. Five years ago a pint of pus removed from right pleura by aspiration, and next day a free incision, with removal of piece of rib, made into the pleura. Complete expansion of lung.

openings or other pernicious contrivances are still being made, with the most undesirable results.

Feeling as I do that these practices can only be due to a want of appreciation of the good results that follow the establishment of a free opening into the pleura I have tried to trace a number of cases of empyema which have been operated on for me during the last few years at the Royal Infirmary. I have written to thirteen and have got in touch with eight. Of these only one is what one might call a complete failure. The left lung appears mostly solid and collapsed, with falling in of the ribs and curvature of the spine. But I do not think we can attribute this to the operation, since it is stated in the notes that at the time of admission the left side of the chest was considerably deformed. Two pints of pus were removed. A second case is that of a tall strongly-built girl operated on in August, 1907, at the age of 17. At present the left (affected) side measures 1 in. less than the right, and the shoulder has dropped somewhat. The movement of both sides of the chest is poor and she evidently takes no trouble to expand it.

The third case, operated on December, 1904, I have not seen, but I hear he has been "all over the world" since, and for a time joined the navy of a South American republic as a cornet player. The other 5 cases have made a recovery so complete that I think that if it were not for the scar it would be impossible to recognize that anything had ever been wrong with the pleura or lung.

R. D., a painter, aged 37, was admitted on October 29th, 1903. By aspiration 20 oz. of pus were removed, and next day a free

incision was made. I saw him this month, after five years. The chest expands well and equally (Fig. 1); the breath sounds are heard well all over; there is no dullness on percussion. His general health is excellent.

W. W., a boy aged 25. Admitted March 20th, 1904, about three weeks after an attack of pneumonia. Left side of chest was distended, and about 2 pints of pus were removed through a free incision. I saw him again this month, nearly five years later. He goes to school, and is in good health. The left side shows slight flattening in front, but measures only $\frac{1}{2}$ in. less than the right. The movements are approximately equal on both sides and there is good expansion, and the breath sounds are normal. The lung seemed to descend a little during inspiration.

Joseph McE., aged 9. Admitted on October 7th last year with signs of a large pleural effusion. The usual operation was performed under eucaïne, and 4 pints of foul-smelling pus was removed. I saw him a few days ago. He looks well, feels well, and goes to school. The chest looks symmetrical; by measurement both sides are equal and expand equally, the total difference between inspiration and expiration being 2 in. Percussion and auscultation normal. The heart is not displaced. By percussion I determined that the lung border descends as it normally does during inspiration.

George K., aged 4, was admitted on August 31st, 1908, with signs of effusion in the left pleura. He had been treated elsewhere for pneumonia several weeks before. Pus was found, and a free incision was made, a piece of rib being removed. He made a satisfactory recovery, but shortly after being sent to a convalescent home he developed scarlatina, so I have not been able to obtain exact particulars of the condition of his lungs.*

The other case I will relate presently, but I will briefly refer there to one which I have met with in private.

A gentleman whose case I knew well had empyema at the age of 40. He was first treated by a tube on the siphon method, the discharge became septic, and two free incisions were made and a tube passed through from one to the other. Some twelve years later I examined him for insurance. Not only was there no falling in of the chest, and the movement of the side was good, but I determined by percussion that there was an actual descent of the lung during inspiration.

This observation, by no means an isolated one, seems, if correct, to imply that the pleural cavity may be actually restored after the closing of an empyema. I have never had an opportunity of investigating this point *post mortem*, but it does not seem to be beyond the bounds of possibility when we remember that surgeons who have

operated on a case of appendicitis or other condition attended by extensive peritoneal adhesions have found no trace of these when they have had to open the abdomen at some subsequent date.

I do not bring forward these few cases as proving that the prognosis in empyema is exceptionally good. In some cases the lung is permanently crippled, though I believe in these the damage has been done before the operation or results from causes, such as cirrhosis, unresolved

pneumonia, or tuberculosis, which are independent of it. My cases are enough to prove that a free opening into the pleura need not be followed by permanent collapse of the lung, nor by any serious interference whatever with its functions.

OPERATION.

The operation now generally performed at the Liverpool Royal Infirmary is the removal of a piece of rib by the subperiosteal method and the insertion of a wide tube with a broad flange. By the local injection of eucaïne or novocain the incisions are made almost painless, and the risk of giving a general anaesthetic is in most cases avoided.

SPONTANEOUS EVACUATION OF AN EMPYEMA.

An empyema overlooked and left alone will, like an abscess elsewhere, make a way out for itself. At the present day an empyema is hardly likely to be allowed to burst externally; the only instance I remember seeing was when I was house-physician twenty-six years ago.

But it is not so very uncommon for an empyema to discharge itself through the air passages. I have notes of 5 cases in my wards during the last eight years in which this accident seems to have occurred. The usual history is that after some acute illness the patient has coughed up a large quantity of matter, perhaps highly offensive to the smell, and the expectoration has continued. No doubt patients sometimes die asphyxiated before we can be called to them. When we find a patient with a his-

tory such as I have sketched and expectorating pus, we try to localize the suppurating cavity, and if we find dullness or other indications of pleural effusion or thickening, we make one or more explorations with the aspirator. If we find pus, a free incision should be made, a tube inserted, and the case treated as one of ordinary empyema. When this is done, the prognosis is no worse than in other cases of the disease, as is illustrated by the following:

P. H., aged 47, a railway worker, was admitted on April 6th last year. About six weeks earlier he had had a rigor, followed

Fig. 2.—George K. Empyema. Evacuated by free incision with removal of piece of rib early in September, 1908. Complete expansion of lung.

Fig. 3.—P. H. Empyema discharged through air passages. Intense fever. Free incision into pleura, with removal of a piece of rib in April, 1908. Complete expansion of lung.

* He was brought to see me on March 15th, when the photograph (Fig. 2) was taken. His appearance was that of robust health. He stood quite straight; the shoulders were level and not rounded. There was no sensible falling in of either side of the chest. The right side at the nipple measured 11½ in., the left 10½ in. Movement was equal on both sides, the percussion resonance and the breath sounds were normal. Except for the presence of the cicatrix it would be impossible to tell that anything had been wrong with the chest.

by cough (probably pneumonia), and after about three weeks copious very offensive expectoration came on. When admitted he was in great distress, coughing incessantly and bringing up purulent fluid. The fever was intense. There was dullness over the right side of the chest, and succussion splashing was heard. I at once removed nearly half a pint of stinking pus mixed with air from the right pleura, which at once relieved his urgent distress, and later in the day my colleague, Mr. Litter Jones, performed the usual operation for empyema. The patient made a good recovery, except that a small piece of rib necrosed and had to be removed at a subsequent operation. When he came to report himself a few days ago he was in good health and at his work. The two sides of the chest appeared equal in measurement and in movement (Fig. 3). There was no dullness on percussion, and, except for the presence of a scar, it would have been impossible to say that anything had been wrong with the chest.

Unfortunately, however, it is not always possible to locate the suppurating cavity. Apparently, after the abscess has burst into the air passages, it may contract into a mere sinus, which continues to pour out offensive matter indefinitely, but eludes the attempt to find it by exploration. How easily this may happen is illustrated by a case I saw in consultation several years ago:

A lady was expectorating offensive matter, and had signs pointing to an empyema at the right base. I made an exploratory puncture, being guided as to the spot by some very localized moist sounds, and found pus. Mr. Bickersteth was called in, and made a free incision and drained the cavity successfully. The cavity was found to be no bigger than a walnut, showing how easily it might have been missed.

It is well known since the time of Hippocrates that patients may recover without operation after evacuation of an empyema through the air passages, but it is only after much suffering and the risk of infecting the other lung, and they sometimes die; and if ever I meet again with such a case, and fail to find the matter by exploration with the aspirator, I shall feel it my duty to advise the making of a free opening and a thorough examination of the pleura and the surface of the lung.

DIFFICULTIES IN DIAGNOSIS.

I will now refer to some cases which serve to illustrate the peculiar difficulties which we may meet with in the diagnosis and treatment of cases with signs suggestive of effusion at the lower part of the pleura.

Suppurative Pericarditis.

Benjamin P., aged 7, was admitted to my ward after a week's illness. The right lung was in a state of pneumonic consolidation. The crisis took place the day after admission, but after the temperature had been normal a few days it became hectic. Dullness persisted, and the heart seemed to be pushed over towards the right. I suspected that an empyema had formed, and made an exploratory puncture over the left lung, and found some pus. The usual incision was made, but little or no matter was found and none came through the tube. Two days later I punctured the pericardium and found a little blood-stained serum containing pneumococci. At the autopsy we found contraction of the left lung. The pericardium was greatly thickened and the heart was adherent to the chest wall. At the back and towards the left of the heart there was a collection of pus, about 6 oz., lodged between the two layers of the pericardium. This I had evidently reached in my first puncture, which must have gone through a thin layer of lung. On operation it could only have been reached by turning the lung aside.

Such a case is probably impossible to diagnose. At the same time it serves to illustrate an important practical point—namely, that signs and symptoms pointing to empyema consequent on pneumonia may be really due to pus in the pericardium, and where exploration of the pleura is negative pyopericardium ought to be thought of. I had such a case only last week.

Subdiaphragmatic Inflammations.

Inflammatory or other diseased conditions below the diaphragm are likely to give rise to signs pointing to disease of the pleura, and these may for a time quite overshadow the primary disorder. Thus I have known the pleura to be opened for an empyema, and hydatids to be found in the pus, and on further exploration the hydatids were found to be merely a colony connected with a much larger mass growing in the liver.

The large single abscess of the liver may, if it points upwards, suggest effusion or suppuration above the diaphragm, and if it is actually attended with a serous effusion in the right pleura, as happened in the following case, the true nature of the case may be overlooked even on the operating table.

A Chinaman, aged 36, was admitted on June 8th, 1904, with signs and symptoms pointing to effusion into the right pleura.

I only saw him just at the end of my visit; his symptoms were urgent and I aspirated him at once and found a considerable quantity of pus. I directed that one of the surgical staff who was in the building should be requested to perform the usual operation for empyema. On my next visit I was informed that this had been done, but that only a serous effusion and not an empyema had been found. On seeing the patient again I found that the liver was enlarged downwards while the diaphragm was pushed upwards and lay against the operation wound in the chest.

I saw at once what had happened in this case. The needle I had plunged into the chest had traversed the lower part of the pleura, missing the effusion, and piercing the diaphragm had tapped an abscess in the liver. The surgeon, however, advancing by successive stages, had laid open the pleura, and finding there a copious effusion of some kind, thought he had done all that was required by evacuating it.

In another case a young woman aged 20, who had never been out of Liverpool, had an irregular temperature, with night sweats, for several weeks, and I suspected she was tuberculous. The only physical signs obtainable were some dullness on percussion and impairment of the breath sounds on the right side of the back as high as the angle of the scapula, and I made a puncture in this region, with a negative result. Two months later she returned to the infirmary with an oedematous swelling over the dull area. I was now confident of the existence of pus, and I explored, and on pushing the cannula deeply in, I drew off 2 oz. of fetid pus, looking like anchovy sauce, which had evidently come from the liver. Here all the indications pointed to empyema, and considering that the patient had never been abroad I do not think a correct diagnosis was possible before it was made. She did well after operation.

Dr. Samuel West alludes to the occurrence of fetid empyema in connexion with ulcer of the stomach, though I do not find any instance of its occurrence in his book. If the fundus of the stomach were a frequent seat of ulcer the association might be fairly common, but in point of fact it must be extremely rare. Only last week, however, I saw in consultation a case in which I believe the empyema had arisen from an extension through the diaphragm of infection and inflammation starting from a gastric ulcer.

Miss B., aged 24, had had gastric trouble for a considerable time, and a year ago was attended for what was thought to be gastric ulcer. At that time she had severe pain coming on directly after food; she had vomiting, though there was no haematemesis. She got better, but towards the end of November the symptoms returned. On the morning of December 26th, possibly not unconnected with the season's festivities, she had severe vomiting and pain referred particularly to the back of the left shoulder. Ten days later a practitioner was called in and found signs of left pleural effusion. The temperature became hectic and there were rigors, and oedema appeared over the left lower ribs. On January 14th, 25 oz. of fetid pus were withdrawn and a free incision made. In the absence of pneumonia or other lung trouble, and of tubercle, with the history suggestive of gastric ulcer and with the knowledge that effusion came on at a time when the gastric symptoms were severe, I feel justified in concluding that the empyema in this instance was due to extension of infective inflammation from an ulcer in the stomach.

In closing this review of the clinical aspects of morbid conditions of the pleura two considerations are especially brought home to me. One is the extent to which the physician has to resort to the surgeon or to the employment of mechanical means for the successful treatment of these cases. But behind all this lies the other and still more important consideration—the means which we possess of arriving at a correct diagnosis. For many years we, as members of a learned and progressive profession, have been more and more attracted to the new and fascinating studies of bacteriology, haematology, and pathological chemistry, and we are not without grounds for believing that if we are ever to arrive at a knowledge of the ultimate processes which underlie the phenomena of health and disease, it will be by pursuing investigations on these lines. But, though I should be among the last to belittle the value of the incubator, the microscope, and the test tube as means for extending our knowledge, I am convinced that in the daily routine of our work as medical practitioners they are of very limited application. Such practical results as they do yield are only of value when obtained by those who are constantly engaged in that kind of investigation, and in the case of the inexperienced they are likely to be absolutely misleading. It is on the physical examination and the careful study of the patient

* I am informed that this patient has made a good recovery. May 11th.

at the bedside, not on work in the laboratory, that we have in the main to rely in the diagnosis and prognosis of our cases; and we will all do well to beware lest, in our eagerness to employ the more recondite proceedings which are continually being offered for our aid, we neglect the first principles of clinical investigation—the training of the eye, the hand, and the ear.

A Clinical Lecture

ON A

CASE OF *BACILLUS PYOCYANEUS* PYAEMIA SUCCESSFULLY TREATED BY VACCINE.

DELIVERED AT THE BRISTOL GENERAL HOSPITAL.

By ERNEST HEY GROVES, M.S., F.R.C.S.,
ASSISTANT SURGEON.

GENTLEMEN,—The boy you see before you to-day, with bright eyes and fat cheeks, is so different from the wretched spectre whom some of you saw with me last autumn, that it may be difficult for you to believe that it is the same patient. But although he has emerged victorious from the struggle with disease, he has been left with lifelong scars of the strife, which afford a ready means of identification.

History.

There seem to be no facts in his past or family history which have any bearing on the case until November, 1907, when at the age of 8 years he developed two abscesses, one over the right Poupert's ligament, and the other on the inner side of the left thigh. He remained in bed for this condition and the right abscess quickly healed, but the left much more slowly; when it had healed he still remained with a painful stiff left hip-joint.

He first came under my care, at the age of 10, in August, 1908, for lameness, due to fixation of the left hip-joint. He had marked adduction of the thigh, which necessitated the pelvis being tilted up on the left side, so as to cause much apparent shortening of the limb. There was also about 1 in. real shortening—that is to say, that whilst the left heel was 3 in. off the ground when the boy stood upright, two-thirds of this was due to the tilting of the pelvis, and only one-third to loss of length in the hip. The left hip-joint was the seat of firm fibrous ankylosis, upon which weight extension had no appreciable effect. A skiagram showed thickening of the neck of the left femur, irregularity of the surface of the head, with a partial upward dislocation. The acetabulum was enlarged upwards—no doubt by a process of caries affecting its superior margin.

Operation.

On August 17th, 1908, the left hip-joint was exposed through an anterior incision and the capsule opened. The head of the femur had not left the acetabulum, but the latter cavity had extended upwards and backwards. The head of the femur and the surface of the hip-socket were carious and divested of cartilage. The diseased bone was thoroughly scraped away and the adducted position of the leg corrected forcibly after tenotomy of the tendons of the adductor muscles. There was much oozing from bone and muscles, and a drainage tube was left in the wound. The aseptic method was used throughout the operation, the skin having been prepared with 1 in 500 spirit and biniodide lotion, and dry swabs with sterilized water for flushing were employed for cleaning the wound. The limb was put up in extreme abduction and with weight extension.

After-history.—Pyæmia.

The next day, in the evening, the temperature rose to 103° F., and it remained near this point for five days, after which it underwent those daily fluctuations characteristic of a hectic fever. The wound was opened up, but the discharge was scanty and more sanious than puriform. I need hardly remind you that this scantiness of purulent discharge from the primary focus of septic infection is always of ominous import, and indicates that the vital powers of resistance and reaction are overwhelmed and that the sepsis is spreading further. A urethral discharge often ceases when acute epididymitis occurs, and the stinking matter from the middle ear dries up when the mastoid or lateral sinus are affected.

The boy became noisy, delirious, and extremely ill, so that he had to be moved to the isolation ward. It was very difficult to get him to take even liquid food, and he became very rapidly emaciated. On August 21st he developed an inflamed swelling of the right thumb. This was opened and found to contain thick gelatinous pus in the last joint. Unfortunately, owing to the pathologist being away on his holiday, the swab taken from this abscess was not examined. During September and October other abscesses developed, and these were chiefly in the region of the pelvis, one very large one being over the right hip-joint. These occurred very rapidly and attained a great size in a very short time. He was treated with injections of various polyvalent antistreptococcus serums without any effect.

Very foolishly I imagined that it was a condition of mixed infection, and I thought, therefore, that vaccines or serums could not be expected to do much good. However, fortunately for the boy, this unwarranted assumption was not allowed to go unchallenged, and on October 25th I asked the pathologist, Dr. Dunkley, to see him. He took swabs from the original wound over the left hip, and from this, to my great surprise, obtained a pure culture of the *Bacillus pyocyaneus*. Now this is a germ which we are too apt to treat lightly. It is true that when it causes blue pus on the surface of an exposed wound it may do but little harm, but this is also the case with other pyogenic organisms—for example, streptococci or staphylococci—but when it exists in pure culture in the depths of the tissues it causes a most deadly septic infection. This has been demonstrated in the case of the peritoneum, for example, by Dudgeon and Sergeant.

A. This represents the actual temperature on the dates given, but it almost exactly represents the course of the temperature for twelve weeks—namely, from August 22nd to November 14th. B. Second injection of vaccine.

Dr. Dunkley prepared an emulsion of the very bacilli grown from the patient's wound, and this, having been heated to 60° C. for an hour, was used as a vaccine. On November 6th 40 millions of the dead bacilli were injected, but there was no appreciable result. On November 14th a further dose of 60 millions was administered, and the next day the temperature remained normal and has remained so ever since. On November 24th, December 8th, January 1st and 16th the injections were repeated, 100 million bacilli being used each time. From the date of the second injection the boy's whole condition has rapidly improved. He has slept quietly, taken his food well, become plump and well nourished, and all the abscesses and sinuses have healed except a small one on the inner side of the left thigh which is quite superficial.

A more striking example of the potency of vaccine-therapy could hardly be imagined.

One further point remains to be told. When his general condition had ameliorated and he could bear to be touched, it was found that the right hip was deformed and displaced. It was much shortened and adducted, and the head of the femur was felt in the buttock. Undoubtedly the joint had been the seat of a pyæmic abscess which by a distension of the capsule with pus had led to a dislocation of the joint. Curiously enough this one patient has exhibited three different varieties of pathological dislocation of his joints. They are:

1. Dislocation by destruction of bony surfaces; illustrated by the tuberculous left hip.
2. Dislocation by destruction of ligaments and the traction of muscles; illustrated by the right thumb.
3. Dislocation by distension of the capsule; illustrated by the right hip.

A skiagram showed the dislocation of the right hip into the sciatic notch, and also the fixation of the left hip in the acetabulum in a position of abduction, a position which compensates for real shortening by a tilting down of the pelvis on that side.

[Note.—The dislocated right hip was reduced by manipulation under an anaesthetic on April 2nd, and put up in a position of eversion and abduction.]

CONCLUSION.

I would summarize the points which I have learnt from this case as follows:

1. The danger of trusting to an "aseptic" system of surgery when dealing with the region of the groin. I now always use 1 in 2,000 biniodide of mercury as lotion for these cases when asepsis is doubtful.
2. The absolute importance of an exact bacteriological diagnosis in every case of suppuration.
3. The great gravity of *Bacillus pyocyaneus* infection.
4. The potency of vaccinal treatment of this infection.

A CASE OF TUBERCULOUS MENINGITIS WITHOUT TUBERCLES.

By F. W. HIGGS, M.B.LOND., M.R.C.P.LOND.,

SENIOR ASSISTANT PHYSICIAN, BELGRAVE HOSPITAL FOR CHILDREN;
MEDICAL REGISTRAR (LAB. ASSISTANT, CURATOR OF MUSEUM),
ST. GEORGE'S HOSPITAL.

(From St. George's Hospital and Clinical Laboratories.)

The following case of tuberculous meningitis seems worthy to be recorded, as it exhibited several unusual and important features:

C. M., a boy aged 8 years, was admitted to St. George's Hospital under Dr. H. D. Rolleston. The history obtained from the patient's mother was as follows: Onset gradual and indefinite. The child had "two severe frights" six weeks and two weeks respectively before admission to hospital. Since the latter the patient has been "morbid," and has complained of pains in the head and has vomited frequently. During the last few days it has been increasingly difficult to get the child to take his food. No history of any head injury. No previous illness except measles. History of tuberculosis in family of maternal grandmother.

Condition on Admission.

Child looks very ill. Lies quite listless, but cries when disturbed. Occasionally shows signs of understanding what is said to him. Some external strabismus of right eye. No voluntary movements of eyes performed. Edges of optic discs blurred, but no definite optic neuritis. Some paresis of left side of face. Occasional twitching movements of orbicularis oris, and clonic movements of the muscles of the upper extremities and of the hamstring muscles on both sides. No note of any head retraction or stiffness of neck. Muscles well nourished. No definite loss of power in any group of muscles. No hyperreflexia. The legs are kept flexed at hip and knee, but can be readily extended passively. No loss of pain sensation. Knee and ankle jerks absent. Plantar reflex gives flexor response on both sides. Superficial reflexes absent. Incontinence of urine and faeces. Respiration rapid (36 per minute). Pulse 128. Temperature 102.5° F. Urine acid, specific gravity 1020; no albumen; chlorides normal. No abnormal signs in chest and abdomen. Lumbar puncture was performed on the day after admission, and one and a half test-tube full (about 50 c.c.) of turbid flaky fluid was withdrawn. The patient became progressively worse, and died comatose two days after admission with temperature 100.6° F. and respirations 48. The bowels had acted normally once or twice a day while the child was in hospital, and no further vomiting had occurred.

Post-mortem Examination.

This was performed nine and a half hours after death. Fairly nourished body. Rigor mortis present.

Meninges.—Some excess of turbid fluid at the base of the brain. The membranes generally are hyperaemic and "sticky" in appearance. No exudate or tubercles on the convexity. A thick layer of fibrino-purulent exudate is present on the inferior surface of the pons. Similar exudate in rather less amount is present in the interpeduncular space. The superior surface of the medulla is adherent to the middle lobe of the cerebellum. There is also similar exudate to that at the base around the vessels in the pia mater deep in the Sylvian fissures. A careful search reveals no tubercles anywhere on the vessels of the meninges or in the exudate. Brain 47 oz., hyperaemic and rather soft. Moderate dilatation of the ventricles, which contain excess of slightly turbid fluid. No tubercles are visible in the choroid plexuses, which appear normal. The brain is not otherwise abnormal. There are no tuberculous foci in it.

Spinal Cord.—The spinal meninges contain a slight excess of turbid fluid, especially in the lumbar region. The cord itself looks oedematous but otherwise normal. No tubercles are visible in the spinal meninges and there is no fibrinous or purulent exudate thereon.

Thorax.—Pleurae normal. Lungs (right 10 oz., left 8 oz.) are congested. There are no signs of milary or other form of tuberculosis in them. Around the left main bronchus is an actively caseating tuberculous gland, the size of a Barcelona nut. Its capsule appears intact.

Larynx, trachea, and thyroid, normal.

Pericardium normal; heart 6 oz., normal, except for moderate dilatation of the right ventricle and tricuspid orifice.

Abdomen.—Peritoneum and mesenteric glands normal; no tubercles. Alimentary tract normal; no ulceration or tubercles. Liver and kidneys normal. Gall bladder and ducts normal. Pancreas congested. Spleen 2 oz., congested; consistence normal. Suprarenals normal. Bladder normal, distended; no obstruction to outflow of urine.

No surgical tuberculosis present. All the organs were searched for milary tubercles, but none were seen.

Microscopical Examination.

Sections of the cortex of the brain were made, showing also the meninges and exudate. Acute inflammation of the meninges and superficial brain substance was present. The meningeal exudate consisted of fibrin and round cells. The cells were mainly large and small lymphocytes, but some polymorphonuclear leucocytes were present. The cells were not spread uniformly throughout the fibrinous mass; in some parts they were thickly aggregated in large irregular clumps, while in other parts there was fibrin with comparatively few cells scattered in it.

All the arteries were surrounded by collections of round cells, and the arterial walls themselves were infiltrated with leucocytes, but no definite endarteritis was present. Many of the cells of the exudate took the stain badly, and appeared necrotic, but nothing suggesting milary tubercle formation was seen; there were no giant cells and no epithelioid cells seen in the sections examined. Similar sections stained by the Ziehl-Neelsen method showed the presence of a considerable number of tubercle bacilli scattered throughout the cortex and exudate (each field containing 12 to 20 bacilli).

The organisms were especially numerous in the close vicinity of the blood vessels.

The examination of the cerebro-spinal fluid removed a few hours before death (the report on which was not received until after the necropsy) showed that the cells were chiefly polymorphonuclear leucocytes, there being only a few lymphocytes. A considerable number of tubercle bacilli were found in the fluid after centrifugalization, and no other organism was present. The lungs and other organs were unfortunately not examined for isolated tubercle bacilli.

The unusual features of the case are: (1) The presence of tuberculous meningitis with much fibrino-purulent exudate at the base of the brain without any milary tubercle formation; (2) the absence of milary tuberculosis of the lungs and other organs; and (3) the great predominance of polymorphonuclear leucocytes over lymphocytes in the cerebro-spinal fluid.

The child only lived two days after admission to hospital, but a diagnosis of tuberculous meningitis was made from the history and physical signs. At the necropsy, however, doubt was thrown on this diagnosis, as, although there was an actively caseating bronchial gland to serve as a primary focus, there was no generalized milary tuberculosis and no tubercles in the meninges, which, moreover, showed much thick fibrino-purulent exudate, mainly posterior-basal in distribution. On the other hand, the general "stickiness" of the meninges and the presence of some exudate around the vessels in the Sylvian fissures favoured the diagnosis of tuberculous meningitis. The doubt as to the diagnosis was accentuated by the cytological examination of the cerebro-spinal fluid. The bacteriological examination of the centrifugized fluid and the sections of cerebral cortex settled the question.

The presence in the sections of cortex and meninges of "diffuse leucocytic infiltration, predominantly perivascular," as described by Delille, is noteworthy, as also is the presence of inflammatory cells scattered diffusely throughout the walls of the arteries. There was, however, no obvious tendency to the formation of circumscribed nodules consisting only of round cells without giant cells or epithelioid cells, such as is sometimes seen in milary tubercles in the lungs and elsewhere in the more acute cases of generalized tuberculosis.

A case reported to the Société Médicale des Hôpitaux de Paris by MM. Sireday and Tinel¹ is similar to the present case in that there was tuberculous meningitis without tubercles, and microscopically there were numerous tubercle bacilli with cellular exudate, "chiefly perivascular," but in their case there was little fibrinous or purulent exudate in the meninges, and "diffuse tuberculous granulations" were found in the lungs. Further, the cerebro-spinal fluid contained chiefly lymphocytes, as is usual in cases of tuberculous inflammation. The

absence of miliary tubercles in the meninges in tuberculous meningitis, though a recognized pathological occurrence, is comparatively infrequent, and especially so when associated with their absence also from the lungs and other organs; and the predominance of polymorphonuclear cells in the cerebro-spinal fluid is certainly rare in tuberculous.

With regard to the reason why tuberculous granulations are not always found in cases of generalized tuberculosis, it may be considered that while general tuberculous infection usually takes the form of a *pyaemia* it may occasionally be only a *septicaemia*, and that the primary tuberculous focus in the first case discharges into the circulation clumps of bacilli with tissue debris, and that these clumps, becoming impacted in the smallest arterioles, cause the formation of miliary tuberculous granulations or "tuberculous pyaemic abscesses" around the blocked vessels, but that in the second case separate bacilli only are discharged into the circulation in considerable numbers, and that these isolated bacilli do not get lodged in the small vessels. The diffuse leucocytic infiltration of the cerebral cortex and the cellulo-fibrinous inflammation of the meninges may be explained as being the result of the irritation of the toxins, and of the bacilli, which have found their way from the blood vessels into the cortical substance and into the cellular tissues of the meninges, these parts especially easily reacting to the tubercle bacillus.

I wish to express my thanks to Dr. H. D. Rolleston for permission to publish this case, and to Dr. Chas. Slater for furnishing the report of the bacteriological examination.

OBSERVATIONS ON AN OUTBREAK OF MEAT POISONING AT LIMERICK.

By E. J. McWEENEY, M.A., M.D., R.U.I.,
D.P.H. IRELAND, CONJUR., F.R.C.P.I.

PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, CATHOLIC UNIVERSITY
MEDICAL SCHOOL, DUBLIN; BACTERIOLOGIST TO THE LOCAL
GOVERNMENT BOARD FOR IRELAND.

IN view of the economic and hygienic importance of the subject of food poisoning, I have thought it well to bring the leading facts revealed by my study of this disastrous outbreak (73 cases with 9 deaths) before a wider circle of the professional public than could be reached by the *Journal of Pathology and Bacteriology*, in which the fuller communication which I have prepared on the subject will appear.

I.—THE OCCURRENCE.

On Tuesday, November 3rd, 1908, at 6 p.m., an alarming attack of illness broke out amongst the inmates of an industrial school for girls at Limerick. The symptoms, ushered in by severe headache, were those of acute gastrointestinal disturbance—nausea, abdominal pain, uncontrollable vomiting and diarrhoea accompanied by tenesmus, and followed, in the severer cases, by the most profound collapse. By midnight, some twenty-eight of the girls were stricken down, and on the following day nearly fifty more became affected, though for the most part not so severely. The first death (that of S. K., aged 13) took place at 7 on the Wednesday morning, after little more than twelve hours' illness. Another child succumbed at 9 that night. On the following day, Thursday the 5th, no fewer than 7 more deaths occurred in rapid succession, the last (that of M. K., aged 13) ensuing at 6.55 p.m., about forty-eight hours after the commencement of the outbreak.

II.—CLASSIFICATION OF THOSE AFFECTED.

The pupils numbered 197, and were divided into four classes. The first or senior class comprised 67 girls between the ages of 13 and 17, and on it fell the brunt of the attack, with 55 illnesses and 8 deaths. The second class, 48 in number (ages between 10 and 13), yielded 10 cases with 1 death. In the third class there were 51 little girls between 7 and 10 years old, of whom 8 sickened—5 decidedly, 3 somewhat doubtfully. The fourth class comprised "babies" between the ages of 3 and 7. There were 31 of these, none of whom took ill. Nor were there any cases amongst the Sisterhood in charge, teachers in training, or servants. Of the 73 cases,

9 died as above stated, and the remainder rapidly recovered, after several days' mild fever, accompanied in several cases by herpes labialis, in others by desquamation of the cuticle, more especially of the fingers. There was no rash. All the recovered cases that were tested (over 20) had agglutinins in their serum, specific for the causative organism.

III.—PATHOLOGICAL ANATOMY.

Assisted by Drs. P. F. Graham (the medical attendant to the institution) and Dr. J. F. Shanahan, I performed, on November 6th, the autopsy of 3 of the cases—namely, S. K., aged 13, the first to die; L. O'D., aged 12½, the only second-class girl who succumbed; and M. K., aged 13, the last to die. The notes were kindly taken by Captain Elsner, R.A.M.C. Eliminating all non-essential details, the following were the chief findings:

Alimentary Canal.—Empty throughout, save for a little creamy fluid; not inflamed, nor ulcerated, nor even hyperaemic, save for a few streaks of capillary engorgement on the gastric mucosa. The mucous membrane of stomach and intestines presented a peculiar pale, swollen, velvety aspect, with here and there patches of white, prominent granules, each as large as a pin's head, projecting under the mucous membrane. They consisted of nodules of tumid lymphoid tissue. Peyer's patches were not tumefied.

The *liver* showed characteristic though not exactly obvious changes in all 3 cases. It was large, soft, hyperaemic, and sprinkled throughout with little, indistinct, pale-yellowish areas or spots. Microscopic examination of the fixed and hardened preparation revealed the most intense fatty degeneration of the liver cells at these places. In one case (L. O'D.) there were areas of haemorrhagic breakdown as big as a pea. The spleen showed no constant change. The kidneys were in a state of cloudy swelling.

The *cardio-vascular system* showed but little change. Endocardium and aortic intima not stained. The volume of the blood was much diminished and the clots were tarry in character. The *lungs* showed only some scattered patches of hyperaemia. The anatomical diagnosis was *cholera nostras* due to food poisoning.

IV.—BACTERIOLOGY.

From practically all of the viscera examined (for details, I would refer to the complete paper), as well as from the discharges obtained from the recovering cases, I succeeded in isolating, either by direct culture or after preliminary enrichment in malachite-green broth, a typical strain of the *Bacillus enteritidis* of Gaertner. The medium used for plating out was Drigalski's litmus-nutrose-lactose-crystal-violet agar. On it the Gaertner colonies were readily distinguishable by their bluish translucent appearance, vigorous growth, and marked tendency to become confluent. The same colonies were obtained from all three cases examined *post mortem*. Avoiding technical details, I will merely say that morphologically this organism is identical with the typhoid bacillus, and is quite as actively motile. It differs from the typhoid bacillus *inter alia*, in its more rapid growth on gelatine, its ability to clear up milk, and to ferment glucose with formation of acid and gas. It differs from an actively motile strain of *B. coli* in the delicate character of its gelatine colonies, its inability to coagulate milk, to ferment lactose, and to form indol. I could find no constant morphological or cultural difference between this strain of Gaertner's bacillus and the paratyphoid B. bacillus (two strains isolated by myself from Irish cases). Neither does it seem to differ morphologically or culturally from the bacillus of Ratn.

Serologically, however, it stands nearer to typhoid than to paratyphoid B., and by comparative agglutination tests I find it to belong to the true Gaertner type (that responsible for the outbreaks of food poisoning at Rumléth, Hanstadt, Morseele, etc., described by van Ermengem and his pupils) and not to the morphologically identical, but serologically distinct, "Flügge-Kaensche" or "Aertryke" type.

I reserve details as to its behaviour on the various coloured and other test media for the complete paper. As regards its pathogenicity for animals, the Limerick strain is very virulent for rats and mice, setting up in mice a fatal epizootic disorder accompanied by yellowish mucoid

or honey-like stools (?mouse-typhoid). Guinea-pigs appear to be immune, at any rate to infection per os, as are also dogs. Rabbits are highly susceptible, not merely to fresh but to old heated cultures administered subcutaneously. A calf, aged 4 months, was killed in seven hours by an injection of 20 c.c.m. culture fluid into the jugular vein. The symptoms were severe dyspnoea coming on in a couple of hours, followed by purging and collapse. I have to thank Professor A. E. Mettam, B.Sc., Principal of the Royal Veterinary College of Ireland, for giving the injection, having the animal watched by one of his pupils, performing the autopsy for me, and giving me facilities for the bacteriological study of the cadaver.

V.—MODE OF INFECTION.

From the first, suspicion was riveted on a certain stew which formed the dinner of the first or senior class only on Tuesday, November 3rd, at noon. Out of 55 girls belonging to the first class who partook of this stew, 53 sickened and 8 died. The serum of the survivors gave positive agglutination reactions with the strain of Gaertner's bacillus isolated. The serum of two of the first class who had their meal in another room, off different food, and who were not ill, gave negative results. It was found afterwards that one of the two girls who partook of the stew and were not ill, consumed only the gravy and potatoes. Their blood gave a distinct positive reaction with the specific bacillus, showing that infection—though unaccompanied by symptoms—must have taken place.

The peccant element in the stew was clearly proved to have been the remains of part of a fore-quarter of beef weighing 38 lbs., which was brought in on Saturday, October 24th. Part of this was cooked and eaten on the following Tuesday, and the remainder was roasted on the Thursday (27th). It was three or four pounds left over from this joint, and allowed to lie in the larder from Thursday till the following Tuesday, that caused the outbreak. This stale piece of roast beef was cut up and added to the stew which formed the dinner of 55 first-class pupils on that day. But how did some second and third-class girls become affected? Subsequent inquiry revealed the fact that four girls (members of the second class) had exchanged their own repast for some of the cold beef in question. All became very ill, and one (L. O'D.) died. Six other girls of this class took cold bacon, with or without a little of the beef. All of these were slightly ill. The bacon is stated to have lain in the larder on the same dish as the beef, and no doubt became infected by contact. The members of the third class to the number of 51 escaped with the exception of 8, only 5 of whom were at all seriously ill, the slight malaise from which the other three complained being ascribed—and no doubt correctly so—to a smart dose of castor oil. Of the 5 who were really ill, 4 received some of the fatal stew from the waitresses (senior girls) who shared their own repast with the little ones. The remaining third-class girl who was ill (A. F.) was found to have occupied a seat at the second-class table, and to have partaken of the cold beef and bacon that were responsible for the illness of members of that class.

VI.—HISTORY OF THE BEEF.

The animal from the carcass of which was cut the piece that occasioned the disaster was described at the inquest as a young Kerry heifer, purchased on June 29th by a certain butcher, who would seem to have attempted, but without success, to fatten it. This butcher seems to have killed the animal on his own premises, on or before October 19th, when he disposed of part of the carcass to another butcher who was the regular supplier of the institution. The contract prices paid by the institution for beef and mutton were 8d. per lb. for the "prime" cuts, and 5d. for the other parts. This piece was sent in at 5d. per lb. by the contractor. No reliable information was obtainable at the inquest as to the condition of the calf at, or shortly prior to, slaughter. From the low price at which the meat was sold to the contractor—3d. per lb.—it seems fair to conclude that the meat could not have been regarded as of "prime" quality. Moreover, the first butcher would appear to have sold the meat at a sacrifice. Two features typical of such occurrences were therefore present in the case. The meat was purchased ready killed by the contractor, and at an unusually low price. The fate

of the remainder of the carcass was not satisfactorily traced at the inquest. The piece sent to the school on October 24th was part of the fore-quarter, weighing some 38 lb. All of this save 12 lb. was cooked and eaten on Tuesday, October 27th, without ill effect. A piece of "ribs" weighing 12 lb. was not cooked, however, till Thursday, October 29th, when it was roasted and partaken of by the teachers without ill effects. Of this joint, about 3 or 4 lb. were left over from the Thursday's dinner, and kept on a dish (together with a piece of bacon) in the larder till the following Tuesday, November 3rd, when it was cut up, most of it put in the stew, and the remainder served out, with or without cold bacon, to girls of the second class. The stew, as already stated, formed the dinner of the first class, but was also obtained by some members of the third class. All who partook of it became ill, with two exceptions, and their serum proved to contain agglutinins specific for the causative organism. All who partook of the beef, as such, also became ill, and also some of those who partook of bacon that had lain in contact with it. The bone of the beef was put in the soup for the "baby" class, and seems to have been innocuous, doubtless because it was thoroughly boiled. As for the stew, that was expressly stated by the cook not to have been boiled, but only warmed up. It would have been most interesting to have examined the beef, but unfortunately when I arrived on the scene not a scrap remained. Despite the fact that it must have been very stale, it does not seem to have given rise to observation with regard to odour, taste, or appearance. Experiments which I carried out by inoculating cold beef with the strain of Gaertner's bacillus isolated from these cases showed that the meat became rapidly and completely pervaded with the organism, and yet exhibited no perceptible alteration. The bacillus would actually seem to have a special predilection for muscular tissue, for I have never failed to isolate it from the muscles of animals that had succumbed to experimental infection with it.

In the stew there was also mutton, but for various reasons, needless to detail here, that could not have been the *fons et origo mali*. Moreover, a large piece sent up to me for examination failed to yield Gaertner's bacillus, even by malachite-green enrichment.

VII.—SUMMARY AND CONCLUSIONS.

This severe outbreak of meat poisoning was caused partly by intoxication (cf. the short incubation period), and partly by infection (cf. the cultivation of the organism from the three fatal and two of the recovering cases). The causal micro-organism was the genuine *Bacillus enteritidis* of Gaertner, which must have been conveyed to the sufferers in the beef; and from the history it seems probable that the calf was sickly, and already harboured the bacillus at the time of slaughter. The escape of those who partook of portion of the same carcass on October 27th and 29th may be accounted for either by unequal distribution of the virus, or by thorough cooking which destroyed it. Some of the infective material must, however, have escaped the roasting of the 29th, and, multiplying rapidly, have rendered the whole piece intensely toxic and infective during the five days that elapsed before the fatal Tuesday when it was finally consumed. The practical lesson to be derived from the observation of this occurrence—the most disastrous of its kind hitherto recorded, so far as the writer knows—is twofold. First, it indicates the need there is for the abolition of the private slaughter-house, and for the inspection of all animals used for human food, both before, during, and after slaughter; secondly, it emphasizes the danger arising from the use of old stale scraps of meat, and especially of beef. If, on economic grounds, such left-over pieces must be used up, the only way of avoiding or diminishing the danger would seem to be very thorough and prolonged boiling. Ordinary examination of such meat may fail to discover any grounds for suspicion.

In the foregoing description I have purposely omitted many interesting points of detail, such as the agglutination reactions of the patients' serum, the distribution of the bacillus in the bodies of the victims, etc. These are reserved for the full paper.

In conclusion, I have to express my heartfelt thanks to the Sisterhood in charge of the institution for the full and complete information and other assistance which they

cheerfully afforded me during my investigation of the outbreak. My thanks are also due to Dr. P. F. Graham, physician to the institution, for his assistance and the trouble he took in collecting the patients' serum. I desire also to thank Dr. Shanahan for helping me at the autopsies and in other ways.

REPORT CXIII.

THE CONDITION OF THE BLOOD IN EXPERIMENTAL RICKETS.*

By LEONARD FINDLAY, M.D.,

ASSISTANT TO PROFESSOR OF PRACTICE OF MEDICINE, GLASGOW
UNIVERSITY; DISPENSARY PHYSICIAN TO WESTERN
INFIRMARY, AND TO ROYAL HOSPITAL FOR SICK
CHILDREN, GLASGOW.

CONCERNING the condition of the blood in rickets there is much diversity of opinion. The majority of authors consider that there is invariably a certain degree of anaemia. Ewing¹ and Cabot,² in their textbooks on haematology, say that there is always a certain degree of anaemia proportionate to the severity of the disease. Cabot, in addition, mentions that examples of polychromatophilia, myelocytes, and nucleated red blood corpuscles are not infrequently observed. Holt,³ Cheadle,⁴ and Ashby,⁵ in their writings on rickets, express practically the same opinion. Not one of these authors, however, quotes any specific example, but merely the conclusions of other observers. Hutchison,⁶ on the other hand, states that severe rickets is often accompanied by no appreciable degree of anaemia; and Pfandl and Schlossmann⁷ say that in rickets there is nothing characteristic of the blood.

Considering the frequency with which rickets occurs, the blood picture has comparatively seldom been the subject of study. In the literature I have only been able to find three papers based on anything like extensive observations.

Morse⁸ in 1897 reported the result of an investigation into the condition of the blood in 20 cases of active and uncomplicated rickets occurring in children between the ages of 7 months and 2 years. He found the percentage of haemoglobin (as estimated by the apparatus of von Fleischl) to vary between 48 and 77, the red blood corpuscles to vary between 3,508,000 and 5,528,000 per c.m.m., and the leucocytes between 5,500 and 18,800 per c.m.m. He observed nucleated red cells in three of the cases, all of which presented some enlargement of the spleen, and in some of these, in which the spleen was greatly enlarged, nucleated red cells, both megaloblasts and normoblasts, were very numerous. In nearly all the cases mention is made of some variation in the size of the red cells, and occasionally poikilocytosis was observed. Morse concludes from his observations that most cases of rickets present some anaemia, which, as a rule, varies with the severity of the disease, and that there may or may not be leucocytosis.

Felsenthal (quoted by Morse⁸) investigated 12 cases of rickets, varying in age from 9 months to 2 years. Three of the patients were very markedly rachitic and had large spleens. He got practically the same result in all the 12 cases. The red blood corpuscles were not decreased in number, or only to a very slight extent, but the haemoglobin was always diminished. Nucleated red cells only occurred in the most severe cases.

Esser,⁹ in a recent paper on the etiology of rickets, discusses the condition of the blood—at least, so far as the number and character of the leucocytes are concerned. He asserts that there is almost invariably—at least, in the early stages—a marked leucocytosis, amounting in some instances to 30,000 per c.m.m., and that the nuclei of the polymorphonuclear leucocytes are more lobulated than normal. He does not, however, give any table of his results, nor does he make any mention of the percentage of haemoglobin or number of red blood corpuscles.

According to Cabot,¹⁰ Hock and Schlesinger found that in a considerable number of cases of rickets, with and without splenic enlargement, the number of red blood cells per c.m.m. was 2,500,000.

As for the rest of the literature, it consists of reports of isolated, or at most two, examples of rickets examined by

the one author. Not infrequently, too, some mention is made of splenic enlargement, and in not a few the blood picture was similar to that found in "splenic anaemia of infancy," so that these results are of very doubtful value. More especially is this the case when one considers that the degree of splenic enlargement in splenic anaemia bears no definite relation to the severity of the anaemia, and also that it is very doubtful, in view of recent observations,¹¹ if uncomplicated rickets is accompanied by any degree of splenic enlargement; and, finally, as Starck¹¹ has shown, that enlargement of the spleen is as common in non-rachitic as rachitic children.

Moreover, much of the diversity of opinion regarding the relationship of rickets to von Jaksch's anaemia is due, in my opinion, to the want of exact knowledge regarding the blood picture in uncomplicated rickets.

Owing to this scarcity of information regarding the condition of the blood in active and uncomplicated rickets I was led to conduct an investigation into the subject both from the clinical and experimental aspect. In this paper I intend to deal chiefly with my experimental results, but it will be advisable to give in addition a brief summary of the results obtained in the case of spontaneous rickets in children.

I examined 30 cases of active and uncomplicated rickets in children between the ages of 12 and 42 months. In order to control these observations I also investigated the blood of 12 children, who to all external appearances were quite healthy, and who most certainly did not present the slightest rachitic manifestation, and who, it may also be stated, belonged to the same class of society. In only 9 of the 30 rachitic cases was there any degree of anaemia. In 2 of these the amount of haemoglobin was only 5 per cent. below the accepted average, and the red cells in no instance were less than 4,100,000 per c.m.m. The majority of the cases, on the other hand, gave notably high blood estimations, so far as the amount of haemoglobin and number of red cells were concerned. For better comparison the cases were divided into five groups, each group comprising an age-period of six months, and the average of each group compared with the average of the controls and the reputed average of authors for corresponding ages. For each age-period the average amount of haemoglobin and number of red cells was in excess of the reputed average, and also of the controls, excepting in one series composed of children between the ages of 18 and 24 months, where the red cells, though still above the normal, were some 800,000 per c.m.m. below the average number as found in the controls. Nucleated red corpuscles were exceedingly rare, only being discovered on one occasion, and myelocytes were notable by their absence. In only 2 of these cases was there an unequivocal leucocytosis, the white cells numbering 20,000 and 30,000 per c.m.m. The child in one of these cases had been suffering for some days prior to the examination from diarrhoea. Of the other 28 cases, 9 gave a normal or subnormal estimation, and in 19 the leucocytes were moderately increased in number, the maximum being 19,000 per c.m.m. Differential counts failed to reveal anything characteristic.

As uncomplicated rickets in children is comparatively rare, I considered it important to corroborate the clinical findings with observations in experimental rickets.

Rickets was induced experimentally in puppies, and periodic examinations of the blood were made before and after the development of the disease. When the rachitic manifestations became very marked the animals were killed, and the histology of the haematopoietic organs studied. In the results recounted below, however, I have not discussed the histological findings in these organs in any detail, as I intend in a later communication to deal with that aspect of the subject.

The blood examinations were always made at about the same time of the day, between 3 and 5 p.m. The sample of blood was taken from a vein of the ear, after the part had been shaved, the haemoglobin estimated by Gowers's haemoglobinometer, and enumerations of the red and white cells made with the Thoma-Leitz haemocytometer. Gowers's solution was used as the diluent for the red cells, and a 3 per cent. solution of acetic acid, tinted with methylene blue, for the white cells, the dilutions being 1 in 100 or 1 in 200 and 1 in 10 respectively. Films were also made and stained with Jenner's fluid, and a differential

* From the Pathological and Physiological Laboratories of the University of Glasgow.

count of 400 to 800 leucocytes made. Films were also at first stained with Ehrlich's triacid fluid, but as it entirely failed to reveal any neutrophile granulations its use was early discarded. The best results were obtained in films stained for two or three minutes with undiluted Jenner's fluid, and then for about ten minutes with the diluted stain and thereafter washed thoroughly. Invariably the eosinophile granulations stained well, but the demonstration of the neutrophile granulations left much to be desired. They always appeared faint and very scanty, but in undoubted polymorphs were sufficiently definite to enable a diagnosis to be made. In no mononuclear cells, either in the blood or marrow, were neutrophile granules detected, so that it was found impossible to distinguish between myelocytes and hyaline cells. This absence of neutrophile granulations in the myelocytes of dog's blood I find is also mentioned by D. Noel Paton¹² in his work on digestion leucocytosis.

In the results of the differential counts I have classified the leucocytes under four headings:

1. *Neutrophile Polymorphonuclear Leucocytes*.—These cells are characterized by a variously-shaped and darkly-staining nucleus, and by the presence of faintly-staining and scanty neutrophile granulations throughout the protoplasm.

2. *Eosinophile Polymorphonuclear Leucocytes*.—These cells only differ from the preceding in the type of granulation, which is large, spherical, and markedly oxyphile in its affinity for dyes.

3. *Lymphocytes*.—Under this heading I have classified all cells, irrespective of their size, which have a relatively faintly-staining circular, oval, or slightly-indented nucleus surrounded by a relatively small amount of markedly basophile protoplasm.

4. *Hyaline and Transitional Cells*.—This class includes the large mononuclears, with fairly abundant clear protoplasm, and cells, which seem exactly similar in type, excepting for the markedly indented nucleus.

EXPERIMENT I.

Male pup. Born May 11th, 1906. This animal was weaned at the age of 4 weeks, and thereafter fed on porridge and milk and subjected to modified confinement. Rachitic manifestations were apparent on July 14th. The pup steadily increased in weight till July 31st, when it weighed 6,597 grams; but from that date until August 23rd it lost 420 grams. The following charts (Nos. 1 and 2) show graphically the results of the weekly blood examinations.

Chart 1: ——— Red cells; ——— haemoglobin; ---- leucocytes.

It will be seen that in spite of the development of severe rickets no anaemia supervened, but that the blood continued to improve steadily in quality. Nucleated red blood corpuscles were met with at almost every examination, but they steadily decreased in number from 1 in 20 leucocytes during the first week to 1 in 600 on the second last day of life. The leucocytes remained fairly steady throughout the development of the disease until just before death, five weeks after definite rachitic manifestations were observed, when there appeared a moderate leucocytosis. Chart No. 2, comprising the absolute counts of the different varieties of leucocytes, shows that the variation in the leucocytic picture depended on the polymorphs and lymphocytes, the other varieties remaining fairly constant. The polymorphs varied between 8,000 and 17,000 per c.mm. until the final observation, when they rose to 26,000 per c.mm. As regards the lymphocytes there was

a gradual rise until the animal was 5 weeks old, after which they diminished in number, and they continued to be scanty during the development of rickets, but during the last two weeks of life they increased again.

The animal was killed on August 23rd. Weight 6,577 grams. Bones showed marked rachitic changes. Heart and lungs were normal. The liver, which weighed 265 grams, was passively congested and the seat of fatty infiltration. The spleen weighed 44.7 grams, and, excepting some passive congestion, seemed normal. The thymus gland weighed 3.9 grams. Sections of the femur marrow, which was unduly abundant, showed it to be slightly more fatty than normal.

EXPERIMENT II.

Male pup, born May 11th, 1906. It was weaned at the age of 4 weeks, and thereafter treated by modified confinement and fed on porridge and milk. It showed undoubted rachitic symptoms on

Chart 2.—Showing absolute number per c.mm. of the different varieties of leucocytes. ---- Neutrophile polymorphonuclears; ---- eosinophile polymorphonuclears; ——— lymphocytes; ——— hyaline and transitionals.

Chart 3: ——— Red cells; ——— haemoglobin; ---- leucocytes.

July 14th, but with exercise these in great part disappeared, only to reappear on again being confined. It steadily increased in weight till July 31st, after which it lost during four weeks 453 grams.

It will be seen from the charts (Nos. 3 and 4) that in this case also there was not the slightest evidence of anaemia. The leucocytes, too, remained fairly constant until three weeks before death, when there was a temporary leucocytosis, due both to a polymorphonuclear and a lymphocytic increase. There was also, as in the former experiment, a gradual rise in the number of lymphocytes from birth,

Chart 4.

with thereafter a fall, which persisted until the final rise three weeks before death.

Killed August 28th. Weight, 4,536 grams. Bones showed marked rachitic changes. Heart and lungs were normal. The liver weighed 155.9 grams, and was fatty. The spleen weighed 18.1 grams, and was slightly atrophied. The thymus weighed 12.1 grams. The axillary and mesenteric lymphatic glands were enlarged, and on minute examination were found to show some lymphatic hypertrophy. The femur marrow was more fatty and more abundant than normally.

EXPERIMENT III.

Female pup, born May 11th, 1906, and treated similarly to animal in Experiment I. This pup was distinctly rachitic by July 14th, and for the last twelve days of life could not walk. She increased steadily in weight until within two and a half weeks of death, during which time she lost 453 grams.

In this case, as in the two preceding experiments, the blood continued after the development of the disease to improve in quality (during the final two weeks of life the red cells averaged 6,400,000, and the haemoglobin 100 per cent.), and, unless on the occasion of the final examination (two days before death), there was no increase in the number of leucocytes: in fact, there seemed to develop a leucopenia after the onset of the rachitic manifestations. During the last week of life the lymphocytes increased enormously, rising from 3,000 to 20,000 per c.mm., but otherwise the differential counts revealed nothing characteristic. Nucleated red blood corpuscles varied from 1 in 25 leucocytes on first examination, when the animal was four days old, to 1 in 500 leucocytes during the last week of life.

Killed August 17th. Weight, 4,309 grams. The bones showed marked rachitic changes. Heart and lungs were healthy. The liver, which weighed 198.4 grams, was fatty, and the spleen, which weighed 8 grams, showed nothing abnormal on microscopic examination. The thymus weighed 3.9 grams. The lymphatic glands were normal. The marrow presented a slight degree of leucoblastic hyperplasia.

EXPERIMENT IV.

Female pup, born March 7th, 1907, and kept under observation from the age of 5 weeks. It was fed on porridge and milk and treated by confinement. Rachitic manifestations were apparent about May 14th. This pup increased steadily in weight till within two weeks of death, after which it lost 652 grams.

In this case there was during the last week of life a fall in the number of red cells, but not sufficient to be described as an anaemia, especially as the haemoglobin still maintained its former level (see Chart 5). The leucocytes throughout remained fairly steady. The leucocytic picture shows a tendency towards a gradual rise in the proportion of the polymorphs, with a corresponding fall in the lymphocytes after the development of rickets (see Chart 6). On May 7th there occurred a marked rise in the number of

Chart 5: — Red cells; --- haemoglobin; . . . leucocytes.

On May 7th there occurred a marked rise in the number of

large mononuclears and transitionals, but with this exception the charts do not present anything abnormal. Nucleated red cells were observed on all occasions except the last three, and varied between 3 in 400 leucocytes on the day of the second examination and 1 in 400 on May 24th, fourteen days before death.

Killed June 9th, 1907. Weight 3,230 grams. The bones showed marked rachitic changes. The heart and lungs were normal. The liver weighed 170 grams; it was markedly fatty, and presented some passive congestion. The spleen, which weighed 14 grams, was congested. The thymus, whose weight was 6.5 grams, was markedly atrophied, the follicles being widely separated and much diminished in size; relatively the corpuscles of Hassall

were increased in number. The femur marrow, which was more abundant than normally, was gelatinous in type, and microscopic examination revealed extensive myxomatous degeneration.

EXPERIMENT V.

Female pup, born March 7th, 1907, of same litter as animal in previous experiment, and treated in a similar fashion. It showed signs of rickets on May 14th, and steadily increased in weight until within three weeks of death. During the last three weeks it lost in weight 793 grams.

The condition of the blood in this case simulated very closely indeed that found in Experiment IV. There developed during the last three weeks of life a slight degree of anaemia, the red cells falling from 6,270,000 to 5,100,000 per c.mm., and the haemoglobin declining from 85 to 75 per cent. A leucopenia, which appeared before the clinical manifestations of rickets, was noted during the last six weeks of life. The differential counts revealed that the leucopenia was mainly due to a diminution of the lymphocytes, the number of neutrophil polymorphonuclears, on the other hand, continuing throughout fairly constant. Nucleated red cells were observed on almost all occasions, and varied between 2 in 400 and 1 in 400 leucocytes.

Killed June 13th, 1907. Weight 2,568 grams. The bones showed marked rachitic changes. Heart normal. Both lungs showed patches of bronchopneumonia. The liver (weight 113 grams) showed numerous polymorphonuclear leucocytes along the portal tracts. The spleen, which weighed 9.5 grams, presented nothing abnormal, excepting for some diminution in the size of the Malpighian bodies. The thymus gland appeared unusually small. The mesenteric and axillary glands were hypertrophied: the lymph sinuses contained many catarrhal cells with blood pigment. The femur marrow presented a slight degree of leucoblastic hyperplasia.

EXPERIMENT VI.

Female pup, born March 7th, 1907, of same litter as two previous animals, and treated in a similar fashion. This animal was undoubtedly rachitic on May 14th. It steadily increased in weight till within seven days of death, but thereafter it lost 595 grams.

In this case also there is a tendency towards the development of anaemia after the appearance of the rachitic manifestations, but not what one would call severe (see Chart 7). There was a leucocytosis, which developed three weeks before death and persisted until the end. This leucocytosis, it will be seen, was entirely due to an increase in the neutrophil polymorphs (see Chart 8). It is most probable that the leucocytosis was due to bronchopneumonia, from which the animal died. Two nucleated red corpuscles were observed on first examination, while counting 500 leucocytes, but they rapidly diminished in number, and were entirely absent on the last three examinations.

The pup died suddenly on June 21st. Weight, 2,948 grams. The bones showed marked rachitic changes. The lungs were the seat of bronchitis with patches of bronchopneumonia. The liver, which weighed 212.6 grams, was congested and presented a slight degree of general

Chart 7: — Red cells; --- haemoglobin; . . . leucocytes.

fibrosis. The spleen weighed 14.17 grams; the Malpighian bodies were small, and

throughout the pulp were many endothelial cells, containing blood pigment.

No thymus gland was detected. The femur marrow showed extensive myxomatous degeneration.

EXPERIMENT VII.

A male pup, born March 18th, 1907, and kept under observation from the age of 4 weeks. This animal was treated as Experiments IV, V, and VI. By May 14th it was undoubtedly rachitic. This animal lost in weight 907 grams during the last two weeks of life, but before that had steadily put on flesh. It seemed ill for some time before death, which occurred on June 9th.

In this case there occurred a very slight diminution in the num-

ber of red cells during the last four weeks of life and immediately after the appearance of rickets; the haemoglobin also during the same period showed a slight average decrease. For two weeks prior to the onset of rickets the red cells had averaged 5,600,000 per c.mm., while afterwards they averaged 5,250,000 per c.mm., and the haemoglobin fell from 90 per cent. to 80 per cent. The most striking feature in the condition of the blood, however, was the leucocytosis which appeared some fourteen days before death. The leucocytes until then had been fairly constant in number, averaging 22,000 per c.mm. Two weeks before death they rose to 56,200, but gradually fell again to 27,000 per c.mm. Differential counts revealed this rise to be due almost entirely to an increase of the neutrophile polymorphs, consequent most probably, as in the preceding case, on the development of bronchopneumonia.

Nucleated red corpuscles were only observed on two occasions: on day of first examination they numbered 2 in 500 leucocytes, and on third last examination 1 in 500 leucocytes.

Died June 9th. Weight 1,672.5 grams. The bones showed marked rachitic changes. The lungs were the seat of an extensive bronchopneumonia. The liver, which weighed 75 grams, was congested, and the spleen, which weighed 3.5 grams, had a normal appearance. The femur marrow was the seat of extensive myxomatous degeneration, with here and there patches of leucoblastic hyperplasia.

EXPERIMENT VIII.

Male pup, born October 2nd, 1907; kept under observation from age of 2 months, and subjected to similar conditions as

sequent to the diarrhoea, but on the animal's recovery this disappeared and in spite of the development of rickets the blood continued to improve in quality. (Chart 9.) Excepting for the fall in the number of leucocytes soon after the onset of diarrhoea, their number continued very

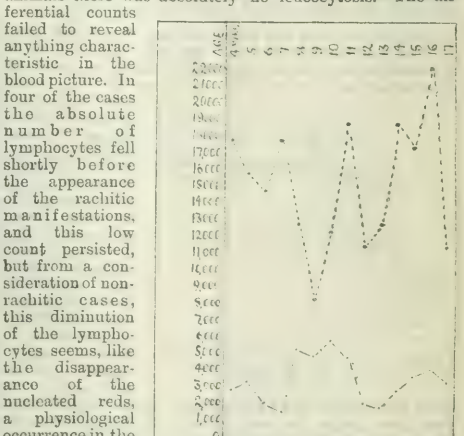

steady throughout. The differential counts revealed a fall in the lymphocytes, which took place shortly before the onset of rickets and continued until the end, and practically synchronous with this a relative increase in the polymorphs. (Chart 10.) Three nucleated reds were observed on the first examination while counting 500 leucocytes, but on no other occasion was a nucleated red corpuscle observed.

Killed February 4th, 1908. Weight 3,150 grams. The bones showed marked rachitic changes. The heart and lungs were normal. Spleen (weight 5.7 grams) showed nothing abnormal. The thymus was atrophied, weighing 3.7 grams. The femur marrow showed a slight degree of leucoblastic hyperplasia.

The following points emerge from a general survey of the above experiments:

In 4 of the 8 animals there was a steady rise in the amount of haemoglobin, and in the number of red cells, in spite of the development of marked rickets. In one case there was a slight fall in the number of red cells at the time of the last observation; in another of the cases the haemoglobin and red blood corpuscles remained constant. In two only did there develop a slight degree of anaemia, and one of these animals, it should be remembered, died from bronchopneumonia, but in the other no cause could be assigned for the anaemia. Nucleated red corpuscles were seldom or never seen after the development of the disease; all the cases presented a certain degree of variation in the size of the red cells.

A degree of leucocytosis appeared in two of the experiments after the rachitic manifestations were detected, but in both this was no doubt due to the bronchopneumonia discovered *post mortem*. On two occasions there developed as a terminal event a leucocytosis, but in four of the animals there was absolutely no leucocytosis. The dif-

ferential counts failed to reveal anything characteristic in the blood picture. In four of the cases the absolute number of lymphocytes fell shortly before the appearance of the rachitic manifestations, and this low count persisted, but from a consideration of non-rachitic cases, this diminution of the lymphocytes seems, like the disappearance of the nucleated reds, a physiological occurrence in the earlier weeks of life, and not a pathological phenomenon. Chart No. 11, which is compiled from the average number of neutrophile polymorphs and lymphocytes of five non-rachitic animals, shows that after the age at which the rachitic manifestations usually appeared, the lymphocytes are, as in the experiments, comparatively scanty.

In the earlier experiments (three in number) the lymphocytes increased somewhat after the onset of rickets, while in the later ones (five in number) the polymorphs underwent the increase, but in two of these latter cases a bronchopneumonia was discovered after death, and probably accounted for the leucocytosis.

Thus experimental rickets is not necessarily accompanied by any anaemia, and when anaemia does appear it is, as a rule, of minor degree, and may frequently be accounted for by some complication. There may or may not be leucocytosis, and this also when it occurs may be the result of some complication. It can at least be truly said that in the blood of animals suffering from rickets there is no marked pathological change and absolutely nothing characteristic.

It is thus seen that these experimental results are in entire accordance with those obtained in the cases of spontaneous rickets, and which I have briefly reviewed above. Of 30 children suffering from active and uncomplicated rickets, only 9 presented anaemia, in not one of which was the number of red cells less than 4,100,000 c.m.m. As a rule, however, the blood estimations were abnormally high. Nucleated red cells were exceedingly rare. In only 2 of the cases was there an unequivocal leucocytosis, 9 presented a leucopenia, and 19 a slight increase in the number of white cells.

THE TREATMENT OF SLEEPING SICKNESS:

A SUGGESTION.

By ANDREW BALFOUR, M.D.,

DIRECTOR, WELLCOMBE RESEARCH LABORATORIES, SHARPTOWN.

I HAVE read with much interest the account of the discussion on cerebro-spinal meningitis at the Sheffield meeting last August. More especially have I noticed the results obtained by Drs. McKenzie and Martin by their method of introducing locally by spinal puncture a highly immune serum which they obtained from the blood of patients who had recently recovered from the disease or, as in two successful acute cases, who were still running a course. These latter were injected with their own serum taken on the sixth and seventh day of their illness respectively.

It has occurred to me that a somewhat similar method of serum-therapy might be tried in cases of trypanosomiasis and sleeping sickness.

Although cerebro-spinal fever and trypanosomiasis differ very markedly—the one being a bacterial, the other a protozoal disease—yet there are certain points of resemblance between them. In both the organism producing the disease is found in the blood and in the cerebro-spinal fluid; at least, this is so in advanced cases of sleeping sickness. In both there is that "lymphatism" described by Westenhoeffer and Symmers in cerebro-spinal fever; and in both the mesenteric glands may show marked hyperaemia and haemorrhage. In both also the final stage of the disease falls on the cerebro-spinal system, and, though the one is an acute, the other a chronic disease, cerebro-spinal fever may run a very chronic course, producing an extreme marasmus which cannot be surpassed even in the closing scenes of typical sleeping sickness. At the same time this resemblance is of minor importance. The question is, if in sleeping sickness the cerebro-spinal canal is a *locus minimae resistentiae*, does the cerebro-spinal fluid show a marked lack of trypanocidal substances? So far as I can ascertain, this matter has not been fully investigated. We know that the blood of patients suffering from trypanosomiasis possesses trypanocidal bodies, and blood serum has been used therapeutically both by subcutaneous and intravenous injection. Why should it not be tried intraspinally?

In the past great difficulty has been experienced in attacking the trypanosomes present in the cerebro-spinal canal, and Kopko has made special efforts to overcome the difficulty when treating patients with atoxyl and other chemical substances. It is true that comparatively few cases of human trypanosomiasis recover, but a suitable serum might be obtained from the blood of patients subjected in the first instance to chemo-therapy. A combined treatment might prove useful, attacking the trypanosomes in the blood by some of the more promising of our present drugs, and attacking those in the cerebro-spinal fluid by performing lumbar puncture and injecting the patient's own serum, or the serum from a case which is improving, obtained by defibrinating and centrifuging the blood. The latest work on the cerebro-spinal fluid in sleeping sickness is that by Broden and Rodhain, but they do not approach the subject from this aspect. The cellular content of the fluid seems to vary, and Nattan-Larrier has reported a very severe case with cerebro-spinal symptoms in which the fluid was very poor in cellular elements. This may point to the canal being a *locus minimae resistentiae*, to employ once more the phraseology of Drs. McKenzie and Martin.

It would seem that, so far as the cellular contents go, the fluid in human trypanosomiasis may approximate to the conditions found in cerebro-spinal fever, a fact which is rather in favour of adopting the line of treatment indicated. I admit it is merely a suggestion, and one possibly based on none too stable a foundation; but in the present state of our knowledge, everything likely to prove beneficial should be tried in cases of sleeping sickness. I am sending a copy of this note to Sir David Bruce in Uganda for his consideration, and I propose to carry out experimental work in this direction here as soon as possible.

If the idea has been voiced beforehand, I can only plead the difficulty of getting at the full literature on the subject, and apologize for having, as one may say, "carried coals to Newcastle."

INJURY TO THE VESSELS IN DISLOCATION OF THE SHOULDER.

By WILLIAM HENRY BATTLE, F.R.C.S.,

SURGEON TO ST. THOMAS'S HOSPITAL, LONDON.

THIS short account of a case of injury to the axillary artery and vein possesses considerable interest, serious injury to the larger vessels of the axilla in ordinary simple dislocation of the shoulder-joint being fortunately rare. When the vessels are torn local signs vary a good deal. In the less common variety a swelling appears a few days or weeks after the injury, and increases rapidly with pulsation; in the second kind a diffused fluctuating swelling forms immediately or within a few hours, without bruit or pulsation, and reaches a large size, pushing forward the pectoral muscles. If this tumour pulsates, the diagnosis of a ruptured artery may be made; if in addition the radial pulse is present, it is extremely probable that the injured vessel is not the main artery; beyond this it is not possible to go (Stimson).

E. M., a stout woman of 70 years of age, was admitted to St. Thomas's Hospital on November 26th, 1908. She stated that on the day before admission she had fallen down and hurt her left shoulder; previously she had been in good health. When examined in the casualty department, it was discovered that she had sustained a subcoracoid dislocation of the shoulder. This was reduced by Kocher's method without anaesthetic. Immediately after reduction, a swelling appeared in the axilla, which increased somewhat rapidly in size; it was also noticed that the radial pulse was absent on that side. When seen in the ward on the same evening, 9 p.m., the swelling in the axilla was said to be larger, and the left radial beat was still absent. She was suffering from shock; the right pulse was small and rapid, 124, and the temperature subnormal. There was, however, no proof that the swelling was rapidly increasing. On the following day the patient was placed under an anaesthetic and the axilla opened, both pectoral muscles being divided. A large tear in the axillary vein was found under the lower border of the pectoralis minor muscle. No wound was present in the artery, but all pulsation had ceased at a

point corresponding with the opening in the vein. The wall of the vein appeared thin, and the tear extended almost across it, so that no attempt to suture it would have been of any use. Ligatures were applied above and below the opening, and the axilla cleared of clot. The wound was closed with silk sutures, the muscles being reunited.

It was considered that in the patient's then condition, an amputation through the arm high up would have proved fatal, and that the better course was to wait until she had recovered from the shock, and there was some indication of the extent of the gangrene which was inevitable.

By December 8th a line of demarcation had formed below the elbow, the hand and forearm being dry and shrivelled; and on this date circular amputation of the arm was performed through the middle of the humerus. No Esmarch's bandage was applied and the only vessel requiring ligature was the superior profunda artery. She did not rally well after this operation, and on December 20th she complained of much pain in the right leg, which was colder than the left and tender to the touch. There was also considerable oedema of the left leg. Dry gangrene of the right leg gradually developed and spread up to the knee.

A similar condition began on the left side, but did not extend.

She suffered much pain in the right leg, and for several days before January 26th, 1909, when she died, it was necessary to give her morphine constantly to relieve it.

At the necropsy there was thrombosis of the popliteal vessels on the right side, and considerable atheroma of the arteries generally. The kidneys were contracted and granular. The left axillary artery was thrombosed, but the coats were not ruptured.

This case is important from a medico-legal aspect, as it shows the extent of the damage which may be inflicted by the dislocated head of the humerus in a patient with atheromatous arteries. There was here no question of injury by the house-surgeon during reduction, and the method of manipulation used was that of Kocher, which is regarded by Stimson¹ as the method of all others best calculated to avoid any risk of injury to the main vessels during the process of reduction. No anaesthetic was used nor was the reduction difficult. In the series of cases collected by Stimson, 44 in number, in only 4 had the axillary vein given way; in the remainder it was the artery or one of its branches. The formation of a thrombus in the axillary artery, with or without injury to the vein, had not apparently been recorded in surgical literature.

SURGICAL CONSIDERATIONS CONNECTED WITH THE ANATOMY OF THE MAXILLARY SINUS.

By A. S. UNDERWOOD, M.R.C.S.ENG., L.D.S.

SINCE the publication of my results in this direction last autumn¹ I have had opportunities of greatly extending those observations. The examination of a very large number of skulls of very varying races and of individuals of every age has left no doubt whatever in my mind that the normal relation of the antral floor to the roots of the teeth is what I then described.

The accompanying figure shows one important fact which has some bearing upon the value of transillumination as a means of diagnosis. If the apices of the roots of the cheek teeth terminated below the antral floor or even protruded a little way into it, transillumination might show a darkness where a small amount of pus was collected in one of the basins between two septa; but if the roots of the molar teeth are embedded in the walls of the cavity, the buccal roots in the outer wall and the palatine root in the inner wall, the thickening of these regions would entirely prevent any transillumination, and the deep pocket of the antral floor descending between these roots might contain things quite undemonstrable by transillumination.

An x-ray photograph, on the other hand, shows such a condition fairly clearly. I have a photograph before me now of a right and left antrum—the right quite clear, the left obviously obscured in relation to the roots of a second or third molar. This left antrum had been pronounced quite normal after transillumination by two authorities.

The next point I wish to dwell upon is the fact that the third and second and first molars in order are most commonly in relation to the sinus, the third molar invariably. Further, the cavity extends a little behind the third molar roots. In the case alluded to above, all the teeth in front of the second molar had been sacrificed as far as and including the lateral, but the second and third molars had been left; their removal later produced a marked result.

I do not wish to suggest that teeth are very often the cause of antral trouble, I do not think they are; but when they are, the third, second, and first molars should be suspected in order, for the third molar is by far the most common offender.

The third point of surgical interest is that the bony septa which divide the part of the sinus embraced by the roots of the third molar from the part in relation with the second molar is generally a simple septum of bone, whereas the septa which are in relation to the front portion of the

cavity are very often traversed at their upper edge by canals in the bone, sometimes closed, sometimes partially open, which convey nerves and vessels across the cavity. I believe that surgeons who are in the habit of doing radical operations on the sinus from a large opening in front (Caldwell-Luc) do occasionally see nervous symptoms ensue consequent upon the breaking down of these septa: if so, these canals, which have not, as far as I know, been described before, may afford a clue to the cause.

The fourth point is that in very rare instances the whole of the third molar region of the sinus is entirely shut off from the rest of the sinus except for an insignificant hole very high up on the nasal side. I have only observed three such cases in the dried skull, but such a condition would in life be very misleading since it looks absolutely like the posterior wall of the sinus, while at the same time there may be a large pus-filled cavity behind it.

I have met with two cases in which the ethmoidal cells extended across the upper third of the maxillary sinus so as entirely to shut off a cavity above it, a cavity which looked at first sight like an attic chamber to the sinus itself.

EPIDERMOLYSIS BULLOSA.

DR. LEONARD B. CANE states in his interesting paper on epidermolysis bullosa (p. 1114) that the eyes in his three cases were unaffected, adding that there was "no evidence of history of phlyctenules or of any ocular disturbance." I have now seen a good many instances of this affection, comparatively speaking of course, and with one exception I have never known the eyes to be involved. The exception occurred in the case of a boy of 15, shown by me at a meeting of the late Dermatological Society of London.¹ The patient, who came under observation in the Skin Department of University College Hospital, presented the characteristic features of epidermolysis bullosa (so-called congenital pemphigus), but I noticed the eyes were not quite right. On closer examination I found there was apparently a looseness of the anterior parts, and came to the conclusion that their state was analogous to that of the skin. This being a peculiar and rare feature, and one I had never seen before, I sent the patient on to the eye department of the hospital for Mr. Flemming's opinion. He was kind enough to report as follows:

Right Eye.—Cornea clear in centre, periphery hazy. The haze is superficial beneath the epithelium. Vessels run into the cornea a short way from limbus.

Left Eye.—Whole cornea hazy, but centre less so than periphery. Three large superficial vessels run over on to the cornea, and can be easily moved over the latter. These vessels are not derived from the anterior conjunctival vessels. The superficial parts of the cornea with these vessels slide upon the underlying deeper layers.

The eyes, I may add, were said to have become affected three months after birth. The ocular condition as here related is very rare. Indeed, I know of no case recorded in dermatological literature in which it has been noted, but the complication may have been observed in ophthalmological practice.

London, W.

GEORGE FERNET, M.D.

COMPLETE RETROVERSION OF THE UTERUS IN THE FIFTH MONTH.

Mrs. W., aged 26, was admitted to the Plymouth Infirmary in the fifth month of her second pregnancy. She was in a state of collapse, the extremities quite cold, the temperature 97°, the pulse 160; the abdomen was distended by a tumour which looked like a full-term pregnancy; the perineum was excessively distended by a large rounded mass, and the anus widely dilated. An oedematous mass (which proved to be the posterior vaginal wall) filled the vagina and projected from it. A catheter was passed with some difficulty and 4½ pints of normal urine withdrawn. This caused diminution but not disappearance of the abdominal tumour, which now assumed a somewhat triangular form with the apex near the symphysis. Strychnine, brandy, and hot-water bottles somewhat revived the patient, and, as soon as it seemed safe, ether was administered by Mr. Stephens Ward and an examination made.

I found it just possible to insert the forefinger between the symphysis and the tumour; the os uteri could not be reached. On examination by the rectum, it was evident that the mass which was bulging the perineum (exactly as a large fetal head does) was the fundus uteri, which was wedged below a well marked sacral promontory.

By careful manipulation it was possible to push the uterus up into the abdomen, when the os could be easily reached, and was found to be dilating. The patient now gradually rallied, and all went well until 5 o'clock the next morning, when she aborted. There was but little hæmorrhage, and the fetus and placenta were expelled in a normal way. Unfortunately she again became collapsed, and, in spite of everything that could be done, she died, apparently of shock.

Her friends stated that she had been for a fortnight at least in the condition above described, and had frequently complained of difficulty in walking.

CHARLES J. COOKE, M.D., M.Ch., R.U.I.

¹ Brit. Journ. of Derm., vol. xvi, 1904, p. 225.

THE CAUSATION OF APPENDICITIS.

THE following account of what appears to have been an aborted case of appendicitis may prove of interest.

One morning in March, 1907, S. W., a male aged 36, felt, on rising from bed, some uneasiness in the right iliac region. This increased until by evening there was distinct tenderness over the region of the appendix, and rest in bed with the right thigh flexed was the only easy attitude. Hot fomentations were applied, and an aperient administered. Decubitus on the left side, with a pillow support, was tried. Two hours later, on waking, a surprising sense of relief of the local symptoms was felt, and there was a call to stool. During this act the concussion of some hardish body against the metal pan of the commode was noticed. This turned out to have been caused by the impact of a body which in size and appearance was not unlike a date stone. There were shreds of lymph adhering to it.

Thereafter recovery was uninterrupted, though a little tenderness over the region of the appendix persisted for a few days.

The specimen has, in the course of two years, become dry and cracked, disclosing a compact seedlike body enveloped by an outer covering, from which it is separate. Its composition has been ascertained.

REPORT BY THE CLINICAL RESEARCH ASSOCIATION.

This concretion is of elongated shape, and of a laminated structure, readily splitting up into concentric layers. After removing layer after layer so as to reach the centre of the mass, there is no organized structure to be found such as might have formed the original nucleus. Analysis of the concretion by chemical and microscopical methods shows its composition to be as follows:

It is to a large extent soluble in hydrochloric acid, leaving a considerable insoluble residue composed of faecal detritus, of which the more resistant vegetable structures, such as leaf hairs and spiral vessels, are readily distinguishable under the microscope.

Extraction of the mixture of acid solution and residue with ether removed a large quantity of fatty acids, which had existed in the original material in combination with calcium and magnesium in the form of insoluble soaps. We have not succeeded in detecting any cholesterol in this ethereal extract, or in an extract of the original material with boiling alcohol.

Further analysis now revealed the presence of abundant ammonio-magnesium phosphate, and a slightly smaller quantity of calcium phosphate, together with the magnesium and calcium which had existed in combination with the fatty acids. There is also a moderate quantity of material soluble in alkali solution but precipitable on the addition of acetic acid, which has the appearance and chemical behaviour of mucin. The analysis shows, therefore, that the concretion consists of calcium and magnesium phosphates, calcium and magnesium soaps, and faecal detritus inclusive of a small amount of inspissated mucus. From the shape of the mass and from its composition it seems very probable that it had been formed in the appendix.

Straits Settlements.

W. SIDNEY SHEPPARD, M.B.

TWO DEATHS CAUSED BY THE FUMES OF FERRO-SILICON.

HAVING seen an account of some deaths which occurred on board an emigrant steamer at Grimsby about Christmas time, which were attributed to the fumes given off from ferro-silicon, I now offer for publication the history of two similar cases which occurred in my practice in 1905.

On October 20th, 1905, I was called to see two children, aged 3 and 4 years respectively, who were lying ill on board a canal boat. On arrival I found one child was dead and the other lying in an unconscious state covered with a cold, clammy sweat, the pulse being hardly perceptible, the breathing slow and light, and the pupils somewhat dilated. On examining the chest, crepitations were to be heard all over; nothing else abnormal was found, but the child died soon afterwards.

I was told that the day after leaving Hull all the family suffered from a feeling of sickness and dizziness on getting up in the morning, which passed off during the day. On the following morning, however, the same symptoms appeared, only now they were accompanied by pain in the body, vomiting, and headache. Again on the third day (the day on which I saw them) there was a repetition of the two previous days' symptoms, but the effects were so pronounced in the case of the two little children that they were utterly unable to get up, and soon lapsed into the state in which I found them on my arrival. None of them,

so far as I could make out, ever complained of an unpleasant taste in the mouth either before or after vomiting, nor did they suffer from cough at any time; but the mother had noticed a peculiar smell in the cabin, which was very pronounced when I went on board.

As I was unable to certify the cause of death a *post-mortem* examination was ordered, but no further information was obtained regarding the cause of death, the only positive fact being some congestion in the lungs. Consequently certain viscera, along with a sample of the cargo, were sent to an analyst, who reported that no poison could be found in the viscera, but that the sample of the cargo proved to be ferro-silicon, a substance which, under certain atmospheric conditions, would give off poisonous gases, which, being inhaled in sufficient quantities for any length of time, would inevitably cause death. In this statement, then, lay the explanation of the symptoms, and of the physical signs found in the lungs during life and also after death.

I understand that deaths occurring with similar symptoms have taken place on boats trading between Sheffield and Hull during their passage up this canal, so that these notes may perhaps be of some interest and use to medical men residing in the vicinity of this canal, and along the banks of the Trent or Humber.

Reports

ON MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF THE BRITISH EMPIRE.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY ROAD, LONDON.

A CASE OF FOREIGN BODY IN THE AIR PASSAGES.

(Reported by A. STROUD-HOSFORD, Senior Resident Medical Officer.)

THE following case, admitted to hospital under the care of Dr. Murray Leslie, presents points of interest.

The patient, a girl aged 4, was brought to the outpatient department on July 6th, 1908.

History.

Her mother stated that she had a troublesome cough, especially in the early morning, accompanied by copious, foul expectoration. This had been going on for two years, but for the last fourteen days the child had been getting worse. As bronchiectasis was diagnosed, the child was admitted and put to bed. There was no history of hæmoptysis, the child was taking food well, and was not losing flesh; no night sweating had been noticed. There was nothing definite in the family history; both father and mother were well, and the only other children were two brothers, who were in good health. The patient was said to have suffered from pneumonia two years previously, and from a second attack eight months before admission. There was also a past history of measles, but no history of ever swallowing a foreign body.

Condition on Admission.

The child was well nourished, peevish and restless; there was some cyanosis of both cheeks, though she was not obviously short of breath. The temperature on admission was 99.8° F., the pulse varied from 124 to 130; the tongue was covered with white fur, and the bowels were regular; the fingers slightly clubbed; the heart was normal, except that the pulmonary second sound was slightly accentuated. The lungs in front showed nothing abnormal; over the left lower lobe behind, however, there was somewhat diminished movement, the vocal vibrations were increased in intensity, and there was marked dullness on percussion. Well-marked tubular breathing was heard in several places, and an increase of the vocal resonance. Some fine crepitations could be heard over the whole of the lower lobe. The sputum, which was examined on several occasions, never showed the presence of tubercle bacilli, but contained

pneumococci in varying numbers. The urine was acid, specific gravity 1019 to 1021, and did not contain any abnormal constituents.

The patient remained much about the same as regards physical signs, but the general condition improved.

After-history.

After remaining in hospital for a little over five weeks, she appeared so well that she was about to be discharged in a day or two, when on August 12th the temperature began to rise, and by August 15th had reached 103° F.; the pulse became very rapid, at one time reaching 180; at the same time the respirations varied from 36 to 40. On examination during this period pneumonic consolidation was detected in the left upper lobe, accompanied by the usual signs and symptoms of pneumonia, together with marked cyanosis. The patient, in spite of all treatment, went rapidly downhill, although the physical signs showed evidence of resolution by the presence of *redux* rales; meanwhile, however, the temperature was swinging, the pulse and respirations remaining rapid, and the patient died on August 22nd, at 6.30 p.m. Treatment consisted first of expectorants, together with creosote by the mouth

Left lung, looking from inner and posterior aspects. A. Trachea, opened on right side; B. bifurcation of trachea; C. left portion of pericardial sac; D. lower portion of pericardium; E. base of lung; F. gangrenous cavity, as seen on surface of lung; G. thickened and dilated bronchus; H. cavity; I. adhesions of lobes; J. nail at orifice of a bronchus; K. oesophagus.

and free diet; antiseptic inhalations were also used (oronasal), but later on the usual treatment for pneumonia was carried out.

Necropsy.

The left lung was bound down to the chest wall, to the upper surface of the diaphragm, and to the left half of the pericardium, by dense adhesions. As they were broken down, portions of the lung substance gave way, and greenish, foul-smelling fluid escaped. The lung was heavy (15 oz.), of a greyish-green colour, and there were scattered purulent areas which on section proved to be gangrenous. The bronchial tubes were thickened and dilated, and contained putrid fluid. At the apex there was a friable pneumonic patch of consolidated lung.

On opening up the trachea and bronchi, a large taintack, 3 in. in length, was found situated about 1 in. below the bifurcation of the trachea. The point of the tack was directed upwards, and the head was obstructing the orifice of one of the lesser bronchial tubes on the left side. A small area surrounding the tack was coated with black pigment.

The right lung was healthy, except for a little emphysema, and weighed 8 oz. The heart, which weighed 3 oz., was rather paler than normal, but otherwise healthy. The liver, kidneys, and spleen were slightly congested. All the other organs appeared to be healthy.

My colleague Dr. Leckie, the house-physician, was good enough to supply me with the drawing here reproduced.

CHARLES BARRETT LOCKWOOD, F.R.C.S., President,
in the Chair.

The Treatment of Shock.

MR. JOHN D. MALCOLM, in a paper on the treatment of shock, quoted Crile to the effect that the arteries were empty, the tissues pale, and the veins dilated in shock. He said he agreed with that, but suggested that the arteries were tensely contracted, whereas Crile taught that the vasomotor centres were paralysed and the vessels relaxed. Crile's initial proposition that the blood pressure was lowered in shock had not been proved. Crile stated that the blood pressure was raised in the splenic vein. When the arterial pressure was lowered and the venous raised it was the sum of the changes that indicated the net results. A rise of specific gravity in the blood had usually been described in shock, indicating a contraction of the vessels and expression of fluids into the tissues. The importance of the flowing of the blood was insisted upon and attention was drawn to the fact that moving fluids were not subject to the law that pressure upon a fluid is transmitted with equal force in all directions to the surface of the fluid. By means of a tube it was shown that when water flowed through it narrowing of its calibre reduced the pressure of water in the narrowest part. Crile's explanation that the heart could not get sufficient blood because of the low pressure in the veins was unsatisfactory and irreconcilable with his previous statement that the veins were engorged. Whether the vessels were dilated or contracted in shock changes of calibre certainly occurred and the conditions necessarily returned to the normal during recovery. Hence it was necessary to divide the treatment of shock into two stages, first to prevent change and later to promote a return to the normal. Crile taught that the vessels dilated as shock progressed, and should be filled with fluid and contracted, if possible; but the speaker held that the vessels contracted in shock, that the fluids were squeezed out of them, and removed from the body as sweat. Hence vaso-dilators and sedatives should be given as shock developed, and the administration of fluids was necessary in the stage of recovery. In regard to this last view Crile was quoted to the effect that as shock deepened the quantity of fluid that could be taken into the veins became progressively smaller, and that in deepest shock fluid so injected escaped into the tissues almost immediately. On the other hand, in the days when fluids were rigidly withheld after operations patients often remained in a state of profound shock for many hours. Now it was known that a free administration of fluid was all that was necessary to ensure prompt recovery in an uncomplicated case. The employment of vaso-constrictors when the arteries were empty and would not dilate nor remain dilated was irrational, but alcohol was useful and undoubtedly improved the pulse in that stage. The action of strychnine had been condemned by Crile. The improvements of the methods of administering anaesthetics, the disuse of irritating antiseptics, the use of the Trendelenburg position and the anticipation of septic and inflammatory troubles by improved diagnosis and prompt treatment were important measures for preventing shock. The greatest danger arose in septic cases in which the vascular changes of shock were already partially produced. In such cases fluid was required and never less than during an operation. It should, therefore, be given subcutaneously during or even before a surgical procedure was commenced, to replace fluid lost and to fill up vessels whenever they tended to relax. Mr. C. R. B. KETZLEY denounced the use of strychnine injections for shock and observed that the use of ether instead of chloroform had lessened the number of cases in which shock occurred. Mr. A. PEARCE GOULD urged the importance of treatment of shock by warmth, rest, and morphine. Dr. ALEXANDER MORISON insisted on the necessity of quickening the action of the heart and suggested the inhalation of nitrite of amyl or the application of warmth. Mr. V. WARREN LOW recommended on the advisability of saline injections into a vein

in very severe cases of shock. Mr. LOCKWOOD mentioned the advantages of the administration of oxygen, and Mr. MALCOLM replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Friday, April 16th, 1909.

'A. R. PARSONS, M.D., President, in the Chair.

Spleno-medullary Leukaemia.

DR. ROWLETTE exhibited specimens from a case of spleno-medullary leukaemia in a woman, aged 58. For many years she had been in good health, but had been treated once for some condition of the heart. She was admitted to hospital in October last complaining of swelling of the feet. There was noticeable a very considerable swelling of the abdomen, and the whole of the left side was filled by a large tumour with a well-defined edge, reaching down to the left iliac region. Its greatest diameter was 16 in. The blood was examined on October 18th, a fortnight after admission, and showed the red corpuscles to be 3,600,000; white cells numbered 640,000, and were of the usual type, except that one saw a larger number of "mast cells" than usual. The haemoglobin was about 70 per cent. The condition of the blood left no doubt as to the diagnosis. The patient was treated with x rays, and showed some improvement. In February an examination of the blood showed haemoglobin about 80 per cent. The red corpuscles were considerably above the normal, and the white had fallen. The condition of the patient's heart was bad all the time, and she died in the beginning of March. The liver was very enlarged, and the heart showed mitral disease, which was responsible in most part for the extreme passive congestion of the liver. The spleen was enormously congested. It was an interesting feature of the case that the red cells increased in number towards the end of life. Professor WHITE said he had never seen a case of leukaemia with so little infiltration of the organs. On more than one occasion he had the opportunity of testing the phagocytic power of the blood, and, while the influence of the serum in this regard appeared to be normal, he was forced to conclude that the phagocytic power of the polymorphonuclear leucocytes was considerably less than normal, and steadily lessened as the disease progressed. Dr. ROWLETTE, in reply to questions, said the patient was exposed to the x rays about every second day, as a routine measure, from shortly after admission to hospital until shortly before her death. There was considerable diminution in the size of the spleen, but she was troubled with severe bleeding of the bowels, and the rays were suspended on a couple of occasions. He did not know that he could put down any definite condition to the rays. It was possible that the thickness of the capsule of the spleen might be attributable to them, but he would not say so positively.

MEDICO-PSYCHOLOGICAL ASSOCIATION: NORTHERN AND MIDLAND DIVISION.—At a meeting at the Grange, Rotherham, on April 20th, Dr. G. E. MOULD, who was in the chair, gave a sketch of the regulations affecting private asylums, and of the difficulties by which the law at present surrounded their work. Though at one time they bore a bad name, yet many good names, such as those of Tuke, Newington, and Hill, had been associated with their foundation. Of such men it was impossible to believe anything but good. The idea that patients were differently treated in private asylums, and that it paid proprietors not to cure them, was absurd. The reputation and prosperity of an asylum depended on its ability to cure the curable and to treat with kindness the incurable. Dr. W. J. VINCENT recorded a case of *Conjugal general paralysis*. The husband, who acquired syphilis after marriage, had no congestive attacks, while the wife had; but in both the concomitant physical signs were well marked. The husband was a commercial traveller, 50 years of age, undersized and somewhat ill-developed. He was happy, contented, and self-satisfied, and showed the usual characteristics of general paralysis. He gradually became demented, and died about two years after admission. The wife, aged 50, was admitted three years after the husband. She was depressed and apathetic, and became steadily demented. She had

several epileptoid seizures, and died about one and a half years after admission. In both cases the post-mortem examination showed the characteristic changes. Dr. KELLY (for Dr. FRENCH) read a paper on *Vagrants*. In his prison experience he had come in contact with the class. The general crimes committed by them were "sleeping out," "wandering abroad," "begging alms," but never any great criminal offence needing much brain work. Out of 194 cases under his observation 122, or 63 per cent., were found congenitally defective in mental power. His conclusions were as follows: (1) Three in every four beggars and vagrants are really feeble-minded. (2) Two out of every three, or 65 per cent., of those found wandering could be shown to be congenitally feeble-minded. (3) The chief causal factor in the condition of this latter class is parental alcoholism. (4) That this particular class is not as a class criminal. (5) That all vagrants and masterless men found to be wanting should be recognized as demented, segregated at special work, farm colony labour for preference, and thus made to defray to the State the cost of their maintenance.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.—At a meeting on May 4th, Dr. MAY THORNE in the Chair, a discussion was held on *Cancer of the breast* with regard to its recurrence. Mrs. SCHARLIEB commented on the apparent capriciousness of recurrence. A patient with advanced carcinoma of the breast, involving skin and muscle, was still alive eighteen years after the operation: whereas another, with a small, freely-movable growth, died two years later from recurrence in the lungs. In view of such cases as the former, operative measures should be urged on all patients who could stand the actual operation. The speaker further emphasized the importance of careful adaptation of the operation to the needs of each individual case, of free removal of the growth, of avoidance of inoculation of the edges of the wound and needle holes, and of refraining from squeezing and cutting into the tumour. The wound should be closed by Mr. Barker's colloid method, after paring the edges with a clean knife. Miss ALDRICH-BLAKE said that among her own 36 cases, she had heard of or seen 9 instances of recurrence, 3 of these being in the scar or its neighbourhood. She thought that prophylactic treatment of the wound by x-rays might be of use in preventing recurrence. The PRESIDENT remarked that the growth had recurred in one-third of her cases operated on in the period 1900-7. She considered that all patients should be given x-ray treatment after operation. Dr. ESTHER CARLING, in a paper on the *Municipal treatment of tuberculosis*, described the system in Edinburgh, where all public and private medical and charitable agencies were co-ordinated. From the central tuberculosis dispensary patients could be sent to the sanatorium or Poor Law infirmary, or they could be referred for help to the Charity Organization Society, or the Citizens' Care Committee. There was compulsory notification. The patients and their families were also given instruction in the home as to what to avoid and what need not be feared. With regard to the establishment of municipal sanatoriums, the speaker said there would be much disappointment and wasting of public money if sanatorium treatment for one to six months was relied upon as the sole means of stamping out tuberculosis. Some system of after-care was necessary, and working colonies for discharged patients were much needed. The system of giving large numbers of patients one month's sanatorium treatment for purposes of hygienic education had much to recommend it.

THE centenary of the first ovariectomy, which was performed by Ephraim McDowell in 1809, was celebrated at the thirty-fourth annual meeting of the American Gynaecological Society, held in New York, April 20th, 21st, and 22nd. A banquet in honour of the occasion was held at the Waldorf-Astoria Hotel on April 22nd by the New York and Brooklyn Fellows of the Society. There will, we presume, be a further celebration later, as the centenary really falls in December. Dr. Riddle Goffe, President of the Society, has through the recognized diplomatic channels asked all foreign Governments to send representatives, who will be expected to present reports on ovariectomy in their respective countries.

Reviews.

HEREDITY.

THE inaugural lecture delivered by Professor W. BATESON, F.R.S., last October, on taking up the duties of the newly-founded chair of biology in the University of Cambridge, has been published in a small volume with the title, *The Methods and Scope of Genetics*.¹ The object with which the chair was founded and endowed for five years partly by an anonymous donor and partly by the university, is the promotion of inquiries into the physiology of heredity and variation (genetics). As Professor Bateson holds that the progress of such inquiries will chiefly be accomplished by the application of experimental methods, especially those which Mendel's discovery has suggested, he devoted his lecture to a description of "the outlook over this field of research in a manner intelligible to students of other parts of knowledge." The lecture is, then, a sort of brief introduction to Mendelism, and as such may be commended to those who desire to gather some general ideas on the subject as a preliminary to a more minute study of some particular part of the very wide field which that theory has opened up. It will bring comfort as well as enlightenment, because to some of us who have found the new doctrines in their most recent developments rather difficult of comprehension, there will be consolation in being told by Professor Bateson that we must not yet think of interpreting these complex phenomena in terms of a common plan. He says:

All that we know is that there is now open for our scrutiny a world of varied, orderly, and specific physiological wonders into which we have as yet only peeped. To lay down positive propositions as to the origin and inter-relationship of species in general, now, would be a task as fruitless as that of a chemist must have been who had tried to state the relationship of the elements before their properties had been investigated.

Any one who wishes seriously to pursue the study of the modern facts and theories cannot, whatever his linguistic acquirements, do better than read Professor ARTHUR THOMSON'S *Heredity*,² a volume to which the attention of readers ought to have been called before this. In it he will find a very comprehensive, careful, and impartial statement of the present position of the subject, and an ample collection of facts upon which to form a judgement. Indeed, the chief objection to which the book is open is that the author as a rule contents himself with marshalling the facts, and adding criticisms of theories advanced to account for them; this gives the impression that his own opinion is held in suspense, and though the words quoted above from Professor Bateson's lecture justify this attitude, yet in a book which is to all intents and purposes a textbook, it is rather disconcerting. A little dogmatism is very helpful to the memory, and if it imposes opinion upon the reader at a first perusal, it eventually stimulates a healthy tendency to question.

In his first chapter Professor Thomson defines heredity, and points out a fact so obvious that it ought to be a truism, but which is apt to be forgotten. This is its fundamental uniformity and continuity. Variation and mutation are established facts, and Mendel's law may be true, but the law is really only a statement of a particular case in which uniformity is displayed in variety, and even mutation is a quantitative rather than a qualitative departure from uniformity. Like begets like, and species breed true, though it is common knowledge that there are minute differences between individuals so that the shepherd knows each sheep. If we grant, as we must, that these small differences—continuous variations—occur, the important question with regard to them is: Are they variations about a mean which is always the same in every generation, or do they occur with greater frequency to one side or the other of the mean so that the species is tending to undergo modification in a particular direction? If we may speak in parables the question may be said to be: Is a species a sea with tides now setting in one direction and now in another, or is it a river slowly but certainly moving in one direction? The

¹ *The Methods and Scope of Genetics*. By W. Bateson, M.A., F.R.S. Cambridge: The University Press, 1908. (Ck. 8vo, pp. 52, 1s. 6d.)

² *Heredity*. By J. A. Thomson, M.A., Reader Professor of Natural History in the University of Aberdeen. The Progressive Science Series. London: J. Murray, 1908. (Demy 8vo, pp. 622, 9s.)

Darwinian hypothesis was that it was a slowly-moving river, that it was by a summation or accumulation of small differences all more or less in one direction that evolution of species occurred. The doctrine of mutation, which in its full development we owe to the botanist De Vries, does not negative the Darwinian hypothesis, but supplements it by directing attention to the occurrence of the sudden large variations which gardeners and breeders commonly call sports. From a pair of ordinary parents there arises a descendant which differs by certain marked characteristics from the parents, and the stock or strain to which they belong. The new stock breeds true, possibly, it may be, in conformity with Mendel's formula, and it is in this way, by carefully exclusive breeding, that the breeds of cattle and dogs, and some at least of the horticulturists' varieties, have been established.

Professor Thomson gives a very full and clear account of Weismann's hypothesis of the germ plasma, by which it is sought to explain some of the facts of heredity. Weismann supposed that in the development of each individual a portion of the specific germinal plasma, assumed to exist in the nucleus, is not used up, but is reserved unchanged for the formation of the germinal cells of the following generation. This very briefly stated, is the theory of the continuity of the germ plasma. In ordinary (sexual) reproduction the offspring has a dual inheritance made up, to begin with at any rate, of equal contributions from the two parents; but the contribution from the father is made up of contributions from his two parents, and that from the mother from her two parents, and so on upwards in the family tree. One of the best

sections in Professor Thomson's book is that in which he states and discusses Galton's law of ancestral inheritance, which it must be remembered rests on statistical considerations. To illustrate it we reproduce from *Nature* (January 27th, 1898, p. 295) a diagram given also by Professor Thomson. It was devised by Mr. A. J. Meston, of

Allen Farm, Pittsburg, Mass., U.S.A., and published in the *Horseman* (Chicago), the leading American newspaper on horse-breeding, in December, 1897. In Mr. Meston's original diagram the number 1 was assigned to the sire, and 2 to the dam, and so on. Mr. Galton modified this by numbering the subject of the pedigree 1, the sire 2, and the dam 3. In this way all male numbers in the pedigree are even and all female numbers odd. The diagram illustrates the law that the total heritage of the offspring is derived as follows: The two parents between them contribute on the average one-half of each inherited faculty, each of them contributing one-quarter of it. The four grandparents contribute between them one-quarter, or each of them one-sixteenth, and so on, the sum of the series $\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \dots$, etc., being equal to 1, as it should be. It is a property of this infinite series that each term is equal to the sum of all those that follow: thus, $\frac{1}{2} = \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \dots$, etc.; $\frac{1}{4} = \frac{1}{8} + \frac{1}{16} + \dots$, etc., and so on. The prepotencies or subpotencies of particular ancestors, in any given pedigree, are eliminated by a law that deals only with average contributions, and the varying prepotencies of sex in respect to different qualities, are also presumably eliminated. Corrections for these can, of course, be made in any particular pedigree, taking care that the corrected series still amounts to 1 exactly. It should be borne in mind that the word "heritage" has a more limited meaning than "nature," or the sum of the inborn qualities. Heritage is confined to that which is inherited, while nature also includes those individual variations that are due to other causes than heredity, and which act before birth. Now,

individual variation in a race that is stable must have a destructive as often as a constructive effect. Consequently its effects balance one another in average results, and disappear from a law which deals only with these. The area of the square diagram represents the total heritage of any particular form or faculty that is bequeathed to any particular individual. It is divided into subsidiary squares, each bearing distinctive numbers, which severally refer to different ancestors. The size of these subsidiary squares shows the average proportion of the total heritage derived from the corresponding ancestors.

This regular mosaic of inheritance is, of course, disturbed by intermarriage of related ancestors. In the case of marriage of first cousins, for instance, 10 and 12, and 11 and 13, are not four, but two persons. It is obvious that if we are dealing with a nation or a community and go back many generations this "reduction of ancestors," as it has been termed, must become more and more influential. It is, of course, not easy to find family trees that go back complete for more than a few generations, but Lorenz and Richter have shown that in the twelfth generation the present German Emperor had at most 533 ancestors, whereas theoretically he might have had 4,096; the effect begins to become particularly marked in the eighth generation, where, instead of 256, there were at most only 116. Professor Thomson quotes, as we gather with approval, Mr. Yule's modification of the late Professor Weldon's statement of the law of ancestral inheritance: "The degree to which a parental character serves as a basis for estimating the character of offspring depends not only upon its development in the individual parent, but on its degree of development in the ancestors of that parent." Yule argues further that "Mendel's laws and the law of ancestral heredity are not necessarily contradictory statements . . . but are quite consistent the one with the other, and may quite well form parts of one homogeneous theory of heredity." Professor Thomson's own comment is that "Mendelian formulae apply to the progeny of known crosses or hybrids, while Galtonian formulae apply to intraracial heredity." It seems probable, so far at any rate as the present stage of the study of the subjects permits an opinion to be formed, that the law of ancestral heredity with its rider as to reduction of ancestors is of the greater importance in medicine.

Professor Thomson supplies a full and fair account of the facts and theories of Mendelism, and in concluding chapters discusses heredity and sex, and some social aspects of biological results. Finally he gives a bibliography, which, though he tells us that it "is simply representative, not in any way exhaustive," occupies nearly fifty pages, a subject index to the bibliography, and a general index to the text.

Professor BATESON'S very recent book, *Mendel's Principles of Heredity*, is a presentation of the observed phenomena, with a relatively brief discussion of their bearing on general conceptions of biology, and on practical breeding. On the latter point Professor Bateson sums the matter up in his preface by stating that though the principles already ascertained will be found of practical assistance in the formation of new breeds and may save many mistakes and waste of time, they cannot materially help in "the business of breeding winners in established breeds . . . for almost always the points which tell are too fine to be dealt with in our analysis." It appears to us that *mutatis mutandis* this last statement applies very exactly to any attempt to apply Mendelian doctrines to medicine in any broad way—the points are, as a rule, too fine to be dealt with in the analysis. In a very interesting passage towards the end of the book is discussed the relation of Mendelism and natural selection. The author begins by pointing out that increased knowledge of the physiology of heredity has abolished an old difficulty because Mendelism teaches that a character appearing in an individual is not in danger of obliteration by crossing with individuals lacking that character because so far as the character depends on factors that segregate no obliteration takes place. There is, he considers, nothing in Mendelian discovery which runs counter to the cardinal doctrine that species have arisen "by means of natural selection, or the preservation of favoured races in the struggle for life," the short definition of the doctrine given by Darwin himself.

The scope of natural selection is limited by the laws of variation, and after pointing out that Mendelian observations are helping us to perceive how precise and specific they are, Professor Bateson continues:

In the light of the new knowledge, various plausible but frequently unsatisfying suggestions put forward, especially by Wallace, Weismann, and their followers, as probable accounts of evolutionary progress must be finally abandoned. It cannot in candour be denied that there are passages in the works of Darwin which in some measure give countenance to these abuses of the principle of natural selection; but I rest easy in the certainty that had Mendel's paper come into his hands, those passages would have been immediately revised.

For Darwin, indeed, Mendelism would have provided sound reasons for a return to his own earlier views. In abandoning his belief in the importance of individual variations, which previously he had held in a form not incompatible with that now demonstrated to be right, he took a step in the wrong direction. The criticism before which he then gave way has proved invalid. To him, most of all men, would the knowledge have come as a delight that progress, even if in a direction unexpected by himself, had been made with that problem the solubility of which he was the first to make apparent to the world.

Professor Bateson prints in this volume translations of Mendel's papers on hybridization and on *Hieracium*, and gives a short biography of the monk and Prilut of the Königskloster of Brunn. It appears to be suggested in this, which is illustrated by three portraits, that Mendel embarked on his experiments with peas, because he did not find himself in full agreement with Darwin's views. If so, it is remarkable that he did not take care that a copy of his paper reached the great naturalist's hands.

Professor Bateson promises in another volume a fuller discussion of the theoretical bearing of the new facts on the general problem of biology; the volume now published is designed to be a textbook, and as such leaves nothing to be desired; it is complete, clearly written, and well illustrated.

NEUROLOGY.

PART I of vol. iii of the new edition of *Quain's Elements of Anatomy*⁴ is too extensive and too full of detail for a student's textbook, but as a book of reference for students and practitioners it is admirable, and will certainly take its place as the most complete account of those parts of the nervous system with which it deals which has yet appeared in this country. It comprises accounts of the general structure and development of the central nervous system, and descriptions of the special structure of the spinal cord and brain, leaving the nerves and special sense organs to be dealt with in Part II. In the last edition the sections on the nervous system were very good, but this volume is still better and more complete. The illustrations are numerous, clear, well executed and well arranged, and the text is crisp, definite, and lucid. As a whole the book forms an excellent survey of present-day knowledge, and the reader will find in its pages not only the author's opinions regarding disputed points, but hints which will enable him to refer to the opinions of other observers. A new departure has been made by the introduction of figures and descriptions of the brains of higher apes, which will prove not only interesting to students of comparative anatomy, but also useful to those who wish to study the records of experiments on apes' brains. Readers interested in the delimitation of the areas of the cerebral cortex will find a good summary of the delimitation work which has been done by means of developmental, histological, and macroscopical methods. The book will no doubt be greatly used as a reference book by teachers, but it is to be hoped that the fact that so much detailed knowledge is available will not induce examiners to expect students to become acquainted during the course of an ordinary medical curriculum with all the minutiae of so complicated a subject.

Ten out of the thirty-three sections in which the great French new treatise on surgery, by Professors LE DENTU and DELHER, is to be completed have already come out, and many of them have been reviewed in previous

numbers of this JOURNAL. The eleventh section to appear, which is the thirteenth of the whole series, is by Professor AUVRAY, and deals with diseases of the cranium and brain.⁵ It may be said at once that this section is fully worthy to take its place by the side of the other volumes of the *Nouveau Traité* that have preceded it. The first forty-five pages of Professor Auvray's work are devoted to the highly interesting history of cranial surgery and trephining, to cranial anatomy and topography, and to the general technique of operations upon the head. The succeeding chapters deal with all the varieties of the traumatic lesions of the cranium and their complications, new growths of the scalp and skull, infective lesions of all sorts—sixty-six pages are given to the complications of otitis media—congenital lesions of the head and brain, and, finally, diverse affections, such as epilepsy, that have not found a place for discussion elsewhere in the book. Diseases of the spinal column and cord are to be considered in a separate volume, which also is to be from the pen of Professor Auvray. A very extensive knowledge and great enthusiasm have been brought to bear on the writing of this volume, and it is large enough to enable Professor Auvray to deal exhaustively with his subject. His style is lucid and agreeable, and as easy to read as we have learnt to expect a French textbook to be. The illustrations are adequate, many of the figures being new and derived from photographs, others being reproduced from older surgical works or the more recent literature. The subject-matter is well arranged, so that the search for information on any particular point is not a matter of great difficulty, and it is also well up to date. The volume would undoubtedly gain by the insertion of more references to the literature, with which the author clearly has a good acquaintance; but extensive lists of references are, after all, a feature of the German textbook rather than of the French, and perhaps cannot fairly be looked for in the latter. The table of contents at the end of the book is so short as to be of little service, and there is no index. The volume is of handsome appearance, but by no means free from typographical errors. It may be warmly recommended to readers in search of a sound and up-to-date textbook of cranial and cerebral surgery.

The fourth edition of Professor DANA'S *Textbook of Nervous Disease and Psychiatry* was reviewed in the BRITISH MEDICAL JOURNAL of August 6th, 1898. The seventh edition is now before us.⁶ In that earlier review the opinion was expressed that the book deserved commendation on the ground of its practical and concise character and form. The same praise belongs to it to-day. That the book has the defects of its qualities will be obvious when it is noticed that the matter relating to all the diseases of the nervous system, central and peripheral, organic and functional, and to all the recognized diseases of the mind, is compressed into some 700 pages of type. Still, the root of the matter is in those 700 pages. Its greatest strength is, perhaps, shown in the chapters on neurasthenia, hysteria, and psychasthenia, the last subject receiving a degree of elaboration on original lines which might well entitle Dr. Dana to be considered an expert in the matter. For those who possess the sixth or earlier editions it may be said that much has been added on the subjects of neuritis, tabes, multiple sclerosis, brain tumours, the ties, and paralysis agitans. The comparison between its rivals that especially suggests itself is with the work on *Nervous and Mental Diseases* by Dr. Church and Dr. Petersen—comparatively recently reviewed in these columns—and, while it may be said that in several respects it is perhaps superior, particularly in its more thorough treatment of the anatomy and pathology of the nervous system, it is, on the other hand, not so pleasant to read, and from the clinical standpoint is probably rather less helpfully arranged. It is, however, well up to date and exact, and although its manner is necessarily curt, its matter is in good proportion.

⁴ *Maladies du Crâne et de l'Encéphale*. Par M. AUVRAY. Nouveau Traité de Chirurgie, publié sous la direction de A. Le Dentu et Pierre Delbet. Fascicule XIII. Paris: J. B. Baillière et Fils, 1909. (Sup. roy. 8vo, pp. 508; fms. 330. Fr. 10.)

⁵ *Textbook of Nervous Diseases and Psychiatry*. By Charles L. Dana, A.M., M.D., LL.D. Seventh edition. London: J. and A. Churchill, 1909. (Roy. 8vo, pp. 794. 25s.)

⁶ *Quain's Elements of Anatomy*. Vol. iii, Neurology. By E. A. Schäfer and J. Symington. Part I. Eleventh edition. London: Longmans, Green and Co. 1908. (Roy. 8vo, pp. 432; fms. 261. 15s. net.)

PATHOLOGY.

In their *Special Pathology*, which has made its appearance shortly after the issue of their *General Pathology*, Professor BEATTIE and Dr. DICKSON again claim special cause for consideration on the ground that their knowledge has been acquired in a particular university, the merits of which they describe in terms of enthusiastic eulogy. We cordially agree with the writers that this university is a most excellent institution, but we prefer to criticize a book on its intrinsic merits, regardless of the author's Alma Mater, and consider special appeals of this nature to be irrelevant. The majority of men take a loyal pride in their own particular university, but generally assume that its especial merits are too well known to need advertisement. This *Special Pathology* is evidently the work of men who are thoroughly experienced in lecturing and demonstrating to medical students. It lays special stress on the importance of studying museum specimens, and contains a large number of excellent illustrations depicting typical examples of pathological lesions. The only possible fault—if it be a fault—which might be found with this aspect of the book is that in many instances the nature of the pathological condition illustrated is so obvious that no student is likely to find any difficulty about it. In addition to assimilating this elementary knowledge, the student ought to receive some training in the differential diagnosis of conditions which he is likely, at the first glance, to confuse; and for this purpose it is well to call his attention to lesions which require a little thought before they can be interpreted correctly, and to teach him how to discriminate. The histological descriptions and illustrations are also good, and we note that the authors adopt the useful plan of introducing brief accounts of normal histological appearances as standards for comparison with the changes produced by disease. We are also glad to find that, wherever possible, they illustrate salient features under a low magnification; this will serve as a useful corrective to the student's common habit of resorting too readily to his high-power lens. At the same time the authors might have advantageously supplemented their instruction by entering more fully into the minute details of cellular morphology.

In Part I of his *Practical Bacteriology, Blood Work, and Animal Parasitology*,¹ Dr. SITT describes in a practical way the methods of cultivating and identifying bacteria, prefacing the description of each group of organisms with what he terms a "key"—that is, a scheme of the characteristics which must be elucidated in order to establish a differential diagnosis. This portion of the book concludes with a short and instructive chapter on immunity which is intended to simplify what the author terms "this bugbear of the medical student." Part II, which is concerned with blood work, is rather brief, and calls for no special comment. Part III, on animal parasitology, is the most useful portion of the book; it gives a concise outline of the many varieties of animal parasites which are of medical interest, and presents their zoological classification and diagnostic features in a convenient and lucid manner. Part IV, on the examination of pathological material in the clinical laboratory, is too brief to rank as an important contribution to this subject.

The *Frankfurter Zeitschrift für Pathologie*² of which we have received the first two volumes, is a publication devoted to the study of pathology in its widest sense. It was founded early in 1907 by Professor Eugen Albrecht, Director of the Pathological Institute of Dr. Senckenberg's Foundation at Frankfurt-am-Main, to commemorate the 200th anniversary of the birth of Dr. J. C. Senckenberg, to whose liberality the foundation owes its existence. In publishing this journal Professor ALBRECHT's intention has been to emphasize the relations and interconnections that

exist between his own science, pathology, and the kindred sciences of physiology, normal anatomy, embryology, biology, and practical medicine, and to give critical discussions of the problems that arise from time to time at the borderlands of these different kingdoms of natural and applied science. The character thus laid down for the journal by its first editor is maintained by the two score and more original papers, and by the critiques, that go to make up its first two volumes; they show so much good work that it is not possible to give any detailed account of their contents in the space at our disposal. An exception, however, must be made in favour of the several excellent articles and discussions from the able pen of the editor, whose sudden death in June, 1908, has robbed the younger school of pathologists of one of its most brilliant exponents. His place as editor has been taken for the time by Dr. A. Knoblauch. Both editor and publisher may be congratulated upon the appearance and get-up of the periodical, which is well printed and well illustrated.

INDIAN SNAKES.

To residents of India the recognition of poisonous snakes is of importance, and Major WALL, I.M.S., tells them how to do this easily in his little book, *The Poisonous Terrestrial Snakes of our British Indian Dominions and How to Recognize them*.¹⁰ The first edition of 2,500 copies was very quickly sold. This of itself is proof of its popularity, and it is equally certain that this new edition will meet with a success similar to, or even greater than, the first. There is some doubt as to how specialists may receive Major Wall's classification. Mr. Boulenger, one of the authorities on the subject, takes osteological peculiarities into account, and he and others will probably object to a classification based chiefly on scales; but, as Major Wall states that he does not disturb Mr. Boulenger's classification, which is the accepted one, harmony may, after all, still reign. The text runs smoothly, and has plenty of diagrams to explain technical terms; such being the case, even though the subject is by no means easy, an eager student should soon get a grasp of the chief details. As far as practical utility goes, it is impossible to tell a poisonous from a non-poisonous snake when only a glimpse of it is seen in the bush; but if the reptile is killed, then it is certainly of value to be sure that it is poisonous before injecting antivenere into any one who may have been unfortunate enough to be bitten. This good and useful little book sums up the matter in a nutshell.

SOME REFERENCE BOOKS.

AMONG a number of reference and other books which have reached us, the first place, perhaps, should be given to the edition of *Burdett's Hospitals and Charities for 1909*,¹¹ which in all its characteristics is precisely on all-fours with its nineteen valued predecessors. It contains somewhat fuller information, however, with regard to nursing homes in this country and the principal Continental cities, and the various chapters in which philanthropic enterprises of all kinds are annually reviewed have, of course, been brought up to date. In one way, perhaps, special interest attaches to this particular issue, as it attempts to present an analysis of hospital expenditure in 1907 made according to the plan introduced by the three Metropolitan Hospital Funds—the revised uniform system of accounts. This is a task which we ourselves performed a year ago in respect of a majority of hospitals in the metropolis, and when the investigation commenced it was intended to furnish simultaneously information of the same kind with regard to the more important hospitals in the provinces. The idea had, however, to be abandoned, as it was found that the moment had not come when the task could be effectively undertaken. It is clear from this volume that, despite the time which has meanwhile elapsed, the position has not greatly altered, for only in the case of a small proportion of the provincial hospitals are details as to the cost per bed supplied on the revised system, and even in these instances there are indications that the figures given have not been derived from books

¹ *Textbook of Special Pathology*. By J. Martin Beattie, M.A., M.D., and W. E. Carnegie Dickson, M.D., B.Sc., F.R.C.P. Edin. London: Reiman Ltd., 1909. (Demy 8vo, pp. 620, 191 illustrations, and 2 coloured plates, 17s. 6d.)

² *Practical Bacteriology, Blood Work, and Animal Parasitology*. By E. R. Sitt, M.D. London: H. K. Lewis, 1909. (Post 8vo, pp. 305, with 85 illustrations, 6s. 6d.)

³ *Frankfurter Zeitschrift für Pathologie*. Herausgegeben von Eugen Albrecht. Vols. i-ii. Wiesbaden: J. F. Bergmann, 1907-8. (Sup. roy. 8vo, pp. 1-220, 221-375, 1-224, 225-389. 7s., 5s., 7s., and 7s. 3d. respectively.)

¹⁰ *The Poisonous Terrestrial Snakes of our British Indian Dominions and How to Recognize them*. By Major F. Wall, I.M.S., C.M.Z.S. Second edition, third thousand. Bombay: The Bombay Natural History Society, 1909. (Roy. 8vo, pp. 78, Rs. 2.)

¹¹ *Burdett's Hospitals and Charities for 1909*. By Sir Henry Burdett. London: The Scientific Press Limited. (Pp. 522, 7s. 6d.)

kept strictly in accordance with its rules. The reform, therefore, has still to be carried through, but the leaven is working, and the remarks made on the subject by Sir Henry Burdett should help to hasten its completion. Nevertheless, the tables supplied by the volume are still of interest, though open to one criticism. They contain so much detail that even persons well versed in hospital accounts must find them difficult to follow, and we suspect that ordinary readers usually pass them over altogether. This is a pity, because it is greatly to be desired that such persons should be encouraged to take an intelligent interest in hospital accounts, and learn how to gauge the efficiency of the administration of institutions in which they are interested. The tables as they stand are a monument of painstaking energy, but it might be better in the interests of greater clearness to sacrifice some of their comprehensiveness, aiming, perhaps, at supplying nothing more than essential figures, such as those indicative of the size of the institution, and of the cost per bed and per outpatient attendance. It seems to us that in this way Sir Henry Burdett would quicker achieve the great purpose for which he has so long laboured.

The edition for the current year of the *City of London Directory*¹² was brought out at the beginning of May. This is a long-established practice in the case of this *Directory*, and has the advantage that the publication is thus free from the errors regarding names and addresses which are commonly to be found in directories finally revised at a time when Christmas and New Year's removals have not yet been completed. In a way the volume is to be regarded not only as a directory, but as a guide to the City of London, for it furnishes brief accounts of the histories of the various guilds, and gives complete lists of all the committees both of the Corporation of the City of London and of the London County Council. Among other useful features are the accounts given of the schools and other charities connected with the City, and an elaborate map. As a whole the work is invaluable to all those who have dealings either with City institutions or with business houses within the famous square mile.

Equally useful in its way is the *Year Book of the Scientific and Learned Societies of Great Britain and Ireland*,¹³ of which the twenty-fifth annual issue has now appeared. Its purpose is to supply information as to the habitation, object, and officials of all scientific bodies in Great Britain and Ireland, together with an account of the work they have done during the preceding year. The way in which it fulfils this end gives it also a value for all literary and scientific workers. One of its features is a list of papers read at each society; and a glance through these is eminently suggestive, for by taking up any volume of the series and studying the titles of the papers recorded it is possible to gauge the tendency and direction of scientific thought at the time. Complete lists of the papers read at the Annual Meetings of the British Medical Association are supplied, and information is given as to upwards of 180 other societies connected with medicine and its practice, apart from those which confine themselves to such subjects as biology, microscopy, and anthropology. We are sure, however, that the British Phrenological Society should not be included in the section devoted to medical societies, even if in a year book of scientific societies there is really any room for it at all.

NOTES ON BOOKS.

MENTAL NURSING.

A SMALL book on *The Care and Nursing of the Insane*, by Dr. J. BAILY, the Medical Superintendent of Hanwell Asylum,¹⁴ has recently been issued. It is a reproduction of the course of lectures which he has given for some years to his asylum staff, already published in serial form in the *Nursing Mirror*, and is divided into five parts, dealing respectively with anatomy and physiology, sick nursing,

the germ theory of disease, the symptoms of disease, and mind and mental diseases. The book is entirely practical in aim and treatment, and should be of great use to the class to whom it is addressed.

Another and much larger book on *Nursing the Insane*¹⁵ comes from America. The aim of the writer, Dr. CLARA BARRUS, is "to furnish special instruction and suggestions to students engaged in caring for the insane, to help new workers to the right beginning, and to aid the more experienced to greater efficiency." This aim the book more than fulfils. It is, we are bound to say, the best book on the subject we have as yet read. It is written by a woman for women, but in the main the instruction and advice given is as applicable to male as to female nurses and attendants. The book is somewhat bulky, but as against this it is exceedingly easily read; and, notwithstanding that it neglects no detail of the proper offices of the nurse, there is not a dry page from cover to cover. The general plan is excellent. It is of little use to nurses to know the comparative proportion of erythrocytes and leucocytes in the blood, or the functions of fibrinogen, or to receive instruction on brain patterns—or often doubtful—cerebral localization; but it is of the last importance that they should understand the therapeutic use and value of every part and minute detail of their work and duty; that they should be taught how and what to observe; should be encouraged to be quick, neat, clean, vigilant, and resourceful, and, above all, sympathetic and unflinchingly cheerful and optimistic. For this latter purpose we know of no better book than this by Dr. Barrus, which at the same time contains a wealth of useful and accurate information for the nurse, admirably arranged and most luckily expressed.

¹²*Nursing the Insane*. By CLARA BARRUS, M.D. New York and London: Macmillan, 1908. (Demy 8vo, pp. 426. 8s. 6d.)

MEDICINAL AND DIETETIC PREPARATIONS.

Lecithin-Agfa.

LECITHIN [has recently been stated to have a valuable effect in cases when administered by intramuscular injection. We have received from Messrs C. Zimmermann and Co. (9 and 10, St. Mary-at-Hill, London, E.C.) a sample of a sterilized solution of lecithin in olive oil, supplied by the Actien-Gesellschaft für Anilin-Fabrikation for the purpose. The lecithin employed, distinguished as lecithin-agfa, is stated to be prepared from pure yolk of egg; one part is dissolved in four parts of olive oil and the solution supplied in sealed ampoules. Some separation of the lecithin appears to take place on standing, but on gently warming the ampoule before opening this disappeared, giving a clear liquid, in which fresh lecithin was readily shown by appropriate tests.

Flavoured Sanatogen.

SANATOGEN, which is stated by the makers, the Sanatogen Company, 12, Chenies Street, London, W.C., to consist of 95 per cent. of casein in chemical combination with 5 per cent. of sodium glycylo-phosphate, appears to have attained considerable favour with the profession, but its use has been limited by the peculiar flavour of the original product, which many persons have found distasteful. The company has sent us a sample of flavoured sanatogen, the flavouring used being lemon oil; the result is, on the whole, very satisfactory, as the lemon almost completely covers the disagreeable flavour to which reference has been made. We have been supplied with an analysis made by Sir Charles A. Cameron, Medical Officer of Health and Public Analyst for Dublin, who found sanatogen to consist of 9.5 per cent. moisture and 90.5 per cent. of dry matter, including 7.35 per cent. of ash. It contained 83.13 per cent. of albuminoids (nearly wholly made up of casein, but including a little albumen), together with 2.2 per cent. of phosphoric acid, a small portion of which existed in the albuminoids, but the by far larger portion was in the form of sodium glycylo-phosphate.

A Compound Syrup of Creosote.

Messrs. J. Maitland and Son (10, Chester Place, Hyde Park, London, W.) have submitted a sample of their preparation "Sirop creophine." This contains creosote (1 minim in one teaspoonful) in combination with lacto-phosphate of lime, together with heroin hydrochloride and other drugs used in the treatment of cough. The presence of creosote is readily recognizable, but the syrup causes no burning taste, and is quite palatable, either alone or with water, with which it mixes freely, forming a bright solution; it is strongly acid.

¹²*The City of London Directory for 1909*. London: The City Press Office. (Pp. 126.)

¹³*Year Book of Scientific and Learned Societies of Great Britain and Ireland*. London: Charles Griffin and Co. (Pp. 352.)

¹⁴*The Care and Nursing of the Insane*. By Percy J. Baily, M.B., C.M.E.din. London: The Scientific Press, Ltd. 1908. (Cr. 8vo, pp. 270. 2s. 6d.)

THE INTERNATIONAL MEDICAL CONGRESS.

The sixteenth International Medical Congress will, as has already been stated more than once in the JOURNAL, be held at Budapest this year from August 29th to September 4th. The congress is under the patronage of the King of Hungary (the Emperor of Austria), who will be represented by his Imperial and Royal Highness the Archduke Joseph.

SECTIONS.

The work of the Congress will be distributed among twenty-one sections as follows:

- I. Anatomy, embryology.
- II. Physiology.
- III. General and experimental pathology.
- IV. Microbiology (bacteriology), pathological anatomy.
- V. Therapeutics (pharmacology, physical therapeutics, balneology).
- VI. Internal medicine.
- VII. Surgery.
- VIII. Obstetrics and gynaecology.
- IX. Ophthalmology.
- X. Diseases of children.
- XI. Diseases of the nervous system.
- XII. Psychiatry.
- XIII. Dermatology and venereal diseases.
- XIV. Diseases of the urinary tract.
- XV. Rhinology and laryngology.
- XVI. Otology.
- XVII. Stomatology.
- XVIII. Hygiene and immunity.
- XIX. Forensic medicine.
- XX. Military and naval sanitary services.
- XXI. Maritime medicine and tropical diseases.

GENERAL MEETINGS.

There will be six general meetings—"not contradictory," as is stated in the official circular, which, we presume, means that discussion will not be allowed.

The following addresses, among others, will be delivered at these meetings:

Professor Baccelli, of Rome: The administration of heroic remedies by the veins.

Dr. E. F. Basiford, of London: On cancer.

Professor R. Kutner, of Berlin (by request of the Prussian Central Committee of Medical Education): Medical education.

Dr. A. Laveran, of Paris: Tropical pathology.

Professor J. Loeb, of Berkeley (University of California): Artificial parthenogenesis and its bearing upon the physiology and pathology of the cell.

An address on representations of disease in the pre-Columbian era will be delivered on one of the days during which the congress is in session by Dr. E. Hollander, of Berlin.

COMMUNICATIONS BY BRITISH MEMBERS.

Among the communications promised by British members of the Congress are:

Section of Anatomy and Embryology.—Professor Anderson (Galway): (1) The occipital bone in primates, and (2) The race types on the Atlantic (Irish) coast; Dr. Fawcett (Bristol): (1) Communications on the development and ossification of the human skeleton, and (2) Models illustrating the development of the human mandible, maxilla, and the sphenoid, with remarks thereon.

Section of Physiology.—Professor Anderson (Galway): Some points of interest bearing on suggestion and nerve reflex.

Section of Therapeutics.—Dr. Bradbury (Cambridge): The causation and treatment of high blood pressure and arteriosclerosis.

Section of Internal Medicine.—Dr. Inman (London) will open a discussion on immunity in its relation to practical medicine.

Section of Surgery.—Mr. Mayo Robson (London) will open a discussion on the chronic form of pancreatitis. Among the communications promised in this section are the following: Mr. Tubby (London), Nerve anastomosis with some results; Sir William Macewen (Glasgow), (1) The development and reproduction of bone, (2) The surgery of the brain and spinal cord; Mr. Moynihan (Leeds), Duodenal ulcer.

Section of Orthopaedic Surgery.—Mr. Robert Jones (Liverpool) will open a discussion on Arthrodesis.

Section of Obstetrics and Gynaecology.—Dr. Thorne (London): On a series of consecutive laparotomies.

Section of Ophthalmology.—Mr. Jessop (London) will open a discussion on the serum treatment of diseases of the eye. Among the papers to be read are the following: Dr. Edridge-Green, Some curious phenomena of vision and colour vision.

Section of Diseases of the Nervous System.—Dr. Head (London) will open a discussion on sensory impulses in the brain and spinal cord. Among the papers to be read is one by Dr. Savill (London) on the influence of toxic blood states on the nervous system. Dr. Bond (London) will read a paper entitled A Description of Long Grove Asylum.

Section of Dermatology and Venereal Diseases.—Sir Malcolm Morris (London): On the treatment of lupus erythematosus. Dr. Whitfield (London): On some changes in the body fluids in relation to skin diseases.

Section of Diseases of the Urinary Tract.—Mr. Freyer (London) will open a discussion on total enucleation of the enlarged prostate, with a review of 600 cases of the operation; and another will be opened by Dr. Newman (Glasgow) on the early diagnosis and treatment of tuberculous disease of the kidney.

Section of Rhinology and Laryngology.—Sir Felix Semon (London) will open a discussion on the diagnosis and treatment of laryngeal cancer. Dr. Watson Williams (Bristol) will show models of the osteoplastic method of operation on the frontal sinus.

Section of Otology.—Mr. Cheate (London) will open a discussion on the infantile types of the temporal bone and their surgical importance; and Mr. Yearsley (London) will open one on the later stages of chronic catarrhal deafness. Mr. Cresswell Baber will read a paper on the treatment of otitis media non purulenta chronica. Dr. Gray (Glasgow) will deal with the relationships of the aquaeductus perilympathicus, the recessus perilympathicus, and the fenestra rotunda in reptilia, aves, and mammalia. Mr. Lake (London) will present a communication on the treatment of vertigo and tinnitus. Dr. Milligan (Manchester) will read a paper on the development of the auditory nerve in vertebrates; and Dr. StClair Thomson (London) will read one on the influence of nasal obstruction in chronic catarrh of the Eustachian tube and middle ear.

Section of Stomatology.—Mr. Goadby (London) will open a discussion on the present state of the scientific basis of the prophylaxis of dental caries; Mr. Turner (Edinburgh) and Mr. Waggett (London) will open a discussion on odontogenic suppurative maxillary and nasal sinusitis and their complications. Among the papers to be read are the following: Mr. Colyer (London): On the influence of the feeding of infants and of adenoids on the deformation of the dental arch. Mr. Hopewell-Smith (London): Some recent researches in dental and oral pathology. Mr. Payne (London): A note on the pathology of the so-called dangerous cyst. Mr. Turner (London): Normal movements of the remaining teeth after extractions. Dr. Wallace (London), the prevention of dental caries.

Section of Hygiene and Immunity.—Dr. Fowler (Manchester) will open a discussion on the sanitary uses of ozone. Dr. Sommerville (London) will read a paper on the teaching of hygiene.

Section of Military and Naval Sanitary Services.—Colonel Macpherson (London) will open a discussion on the necessity of uniformity in the use of diagnosis tallies in different armies.

Section of Maritime Medicine and Tropical Diseases.—Dr. Lamb (Kasauli) will open a discussion on the etiology and epidemiology of plague; and Drs. Rufer and Willmore (Alexandria) will open one on the annual epidemics of dysentery during the Mussulman pilgrimage.

The general secretary of the congress is Mr. Em. de Gross. Applications relative to the congress should be addressed up to August 24th to the Secretariate, VIII Esterhazy utca, 7, Budapest; after that date they should be addressed to the general offices of the congress.

EXCURSIONS.

Excursions to various places of interest have been arranged. Among the places to be visited are Kolozsvár, the ancient capital of Transylvania; Marosújvár, with its salt mines, lighted by electricity; the High Tatra, described as "the El Dorado of tourists"; the famous ice-cavern of Dobšina; Lake Balat, often called the Hungarian sea; the Lower Danube; Constantinople, Athens, Corfu, and Trieste; Bosnia-Herzegovina, Dalmatia, and the Hungarian littoral. Applications relative to lodgings and excursions should be addressed to the Central Travelling-Ticket Office, IV, Vigadó-ter, 1, Budapest, Hungary (Telegraphic address, Menetjegyiroda-Budapest).

OTHER MEETINGS.

The International Medical Press Association will hold its general meeting at Budapest before the congress.

The Permanent Bureau of the International Bureau for the Protection of Infancy will meet at Budapest on August 28th.

MODERN PATHOLOGY AS ILLUSTRATED AT ST. BARTHOLOMEW'S HOSPITAL.

PATHOLOGY has greatly broadened its horizon during the past two decades, and the new block now provided at St. Bartholomew's Hospital is striking testimony to the extent and significance of the change. The building was formally declared open on May 7th by the Lord Mayor of London, the brief ceremony concluding in the Great Hall of the hospital. A short address was there delivered by the Treasurer of the hospital (Lord Sandhurst), and a golden key presented to the Lord Mayor as a memento of the occasion by the architect (Mr. E. B. l'Anson). The new premises were then visited by the general company, and tea served at tables round the fountain in the quadrangle, where a band was playing. In his address Lord Sandhurst observed that exactly 700 years had passed since the date of the first recorded public transaction between the Lord Mayor of London and St. Bartholomew's Hospital. This was in the reign of King John, and took the form of a visit from the City representative of the time—Henry FitzAylwyn—to make arrangements with the hospital for the use of certain land near it as a burial ground for citizens who might die during the general interdict proclaimed A.D. 1208.

Another link with the past which Lord Sandhurst did not specifically mention is that the new building occupies the site of the house which Joanna Astley, nurse to King Henry VI, rented from the hospital on her retirement. It stood just opposite the Church of St. Bartholomew the Less—the church of the hospital and of the parish which it constitutes—on the right-hand side of the principal entrance of the hospital, commonly known as Henry VIII's Gateway. This house later on gave place to the row of shops, occupied by instrument makers and medical booksellers, familiar to so many generations of St. Bartholomew's students. Among them was a precursor of the modern tea shop—one which, even thirty years ago, when medical students were still esteemed "rowdy," was a formidable rival to "Bell's," "The Vi," and the College dining-hall itself. All of them have now disappeared, their place being occupied by the new pathological block, the library and museum, and the new out-patient entrance. With the exception, therefore, of the frontage of the new Post Office, the whole of the east side of Smithfield and Giltspur Street from Little Britain to Newgate Street is now faced by hospital buildings.

The new block is a building of six stories if the basement is included in the count, as it should be, since it is of an important character, has a separate entrance, and provides accommodation for the seemly keeping of the dead pending interment. Its arrangements include a waiting-room and a small mortuary chapel where bodies can be viewed by coroners' juries or friends of deceased patients. Communicating with this chapel by a short passage is a mortuary proper, this being provided with a refrigerating apparatus capable of preserving for an indefinite period as many as eighteen bodies, and a special lift by which bodies can be raised into the *post-mortem* department. This is on the highest story, its principal room being provided with top lights, six necropsy benches, and adequate supplies of water sprays and washing troughs. It is an excellent room which will both minimize the unpleasantness inevitably attaching to *post-mortem* investigations and facilitate accurate and informing work.

The other four floors of the building provide accommodation (1) for pathology in the old sense of the term, (2) for that clinical pathology which often nowadays helps so greatly to elucidate diagnosis and direct and assist treatment, (3) for chemical pathology which is still in its infancy, (4) for tutorial work and for conferences between members of the staff engaged in the general work of the hospital. The fourth floor communicates by a bridge corridor with the museum, and thence with the general library, the school buildings, the resident's quarters, and the out-patient department. In several of the rooms are tablets bearing the names of persons in whose memory they have been equipped, and one is appropriately dedicated to the pathologist Kankhack, whose death some twelve years ago was such a grave loss to St. Bartholomew's, to Cambridge, and to science in general.

Generous as are the proportions of the building, it is

evident nevertheless that the amount of space to be devoted to each particular object has been carefully thought out. For this reason the mere multiplicity of the rooms and their size is a striking object lesson in the extent of the work now expected of the pathological department of a great hospital. Better evidence still, perhaps, is afforded by the arrangements which have been made for the conduct of the work in this building. As a whole it is in charge of Dr. Andrewes, pathologist of the hospital, whose principal assistant is Dr. Mervyn Gordon. These two officers have as lieutenants six trained pathologists, two of whom will devote themselves entirely to investigations connected with clinical work of the hospital and researches necessitated by it, while the others will give part of their time to similar occupation and part to the training of students who have still to pass their examinations, or of those who require special pathological instruction in order to fit them for their duties in the wards. The general routine work will be done by pathological clerks, one of whom is attached to each physician and each surgeon and to the heads of special departments. Each of them is provided either with a special bench in a general laboratory or a separate room in which to prepare his reports on ward specimens, the results being tested and controlled by Dr. Andrewes's general assistants. Altogether, therefore, there will be some twenty-five men constantly engaged in pathological inquiry in this building, apart from general students. The fact that it is now considered necessary that every member of the treating staff of a hospital should be provided with a pathological clerk of his own brings out perhaps more vividly than would anything else the repute in which modern pathological methods are held, and the reliance which physicians and surgeons alike are nowadays disposed to place upon the information supplied to them by laboratory methods. It is not so long ago that the whole of such work was everywhere represented by a stand of urine-testing tubes and possibly a microscope on a side table in a ward. On this account, apart from its interest to pathologists in particular, the building is well worth a visit. For the general observer its outstanding features perhaps are the thoughtfulness of the arrangements for sparing the friends of deceased patients all unnecessary pain, and the mine of invaluable information represented by the room in which the clinical and pathological records of the hospital are stored and classified. Undoubtedly this building will do much to promote the chances of successful treatment in the wards, and go far towards ensuring the utilization of scientific methods among the general practitioners of the future.

The funds out of which it has been erected have been supplied, we understand, partly by friends of the hospital and partly by supporters of the school, while all rooms to be used mainly for tutorial purposes have been equipped entirely from the latter source. At one time it seemed as if the plan of rebuilding St. Bartholomew's piece by piece was not particularly wise, but it is now clear that by adopting it the institution as a whole will eventually be much more up to date than it would have been had all its parts been rebuilt simultaneously. It is to be hoped that the funds necessary to carry out the further changes in view will soon be forthcoming.

AN Egyptian League against Tuberculosis was formed at Alexandria in 1902. Beginning with one dispensary, it has now three, all of which are doing good work. Funds are being accumulated for the establishment of a sanatorium. The President of the League is Dr. J. Schiess Pasha. A movement for the formation of a similar organization in Cairo was suggested three years ago, but so far nothing has come of it.

MESSRS. SIEMENS BROTHERS AND CO., Caxton House, Westminster, have issued a supplement to their Electro-Medical Catalogue containing particulars of various types of switchboards for use in rapid and instantaneous radiography. The feature of chief interest about them is that they can be added to ordinary x-ray outfits, and by merely setting the time relay and closing the switch the apparatus becomes ready for rapid work. This will be appreciated by the medical man who, after using his tube for treatment or for screen observation, finds it necessary to make a short exposure. It is essential, however, that existing outfits, to be eligible for this additional convenience, should have at least a 16-in. spark induction coil, and a triple Wehnelt interrupter.

UTERINE CANCER.

APPEALS BY THE BRITISH MEDICAL ASSOCIATION.

At the Annual Meeting of the British Medical Association at Exeter in 1907 the Section of Obstetrics and Gynaecology adopted a resolution requesting the Council of the Association to appoint a committee to consider the best means of disseminating knowledge of the importance of the early recognition of uterine cancer. That committee presented a report which was considered and generally approved by the same Section at the Annual Meeting of the British Medical Association in Sheffield in 1908.

At its meeting on April 28th the Council of the British Medical Association approved the publication of the following appeals to the medical profession and to midwives and nurses respectively.

A.

AN APPEAL TO MEDICAL PRACTITIONERS TO PROMOTE THE EARLIER RECOGNITION OF UTERINE CANCER.

The attention of all Medical Practitioners is directed to the necessity of emphasising the curability by operation of uterine cancer in its early stages.

The adoption of a more extensive operation by the abdominal route has made it possible to deal successfully with cases hitherto regarded as inoperable, and to remove more of the pelvic cellular tissue as well as a portion of the vaginal walls; it is in these situations that recurrence is prone to develop.

Many patients now present themselves for examination and treatment when the disease is considerably advanced, and it is hoped that by a widespread and accurate knowledge of the early signs and symptoms the number of such patients will gradually diminish.

Special attention is directed to the following:

1. Cancer of the uterus is at first a local disease.
2. Cancer of the uterus is often a curable disease.
3. Operation is the only satisfactory method of treatment.
4. The earlier the disease is recognised the more hopeful are the prospects of treatment.
5. The risk of operation in early cases is slight, and the chance of permanent cure is good.
6. The recognition of early cancer is not usually difficult, and the disease should not be overlooked by the medical attendant.
7. A medical practitioner who fails to make a physical examination of a patient exhibiting any of the symptoms of uterine cancer incurs grave responsibility.
8. Treatment of symptoms without a physical examination is unjustifiable.
9. Early cancerous ulcers should not be treated with caustic; their appearance becomes masked, and valuable time is lost.
10. It is an error to wait and observe in order to arrive at a diagnosis.
11. In doubtful cases a diagnosis must and can be made in a few days.
12. To examine, to diagnose, and then to treat, should be the rule in all cases.

Symptomatology.

Uterine cancer is at first a painless disease which does not affect the general nutrition.

The early symptoms of cancer are:—Irregular bleeding of any description, even if there be only traces; bleeding post coitum; and watery, blood-tinged discharge. There may be no loss of strength or wasting, nor any condition to alarm the patient. Pain, wasting, profuse bleeding, and foul discharge, indicate advanced disease.

As the majority of cases occur between the fortieth and fiftieth year, the symptoms are too often regarded by the patient as due to "change of life." The medical attendant should not accept this assumption until he is satisfied that cancer does not exist.

Bleeding, however slight, occurring after the menopause, should give rise to suspicion that cancer is present.

Examination.

If a patient with any of the above symptoms comes for advice, a careful visual and bi-manual examination must be made before any treatment is recommended.

Should a patient refuse to be examined—and this is exceptional when the situation is explained—the medical attendant should decline any further responsibility, and no treatment should be advised. The examination should be made, even if bleeding is present, as valuable time may be lost by postponement until the hemorrhage has ceased.

It is most important to observe rigid aseptic precautions in all manipulations.

In the examination, the condition of the vaginal portion of the cervix and of the cervical canal should be carefully noted.

In the early stages new growth may be found on the surface of the vaginal portion of the cervix, in the lining of the cervical canal, or in the substance of the cervix. Any prominence on the surface of the vaginal portion or any ulceration, *i.e.*, a definite loss of substance, should at once arouse suspicion. A nodule or nodules, hard, inelastic, or irregular in outline, felt in the substance of the cervix, suggest the presence of cancer. If the whole cervix be affected, the relative hardness as compared with the soft elastic body is pronounced.

The detection of high-lying cervical cancers, and cancers of the body of the uterus, is only possible after curettage or digital exploration.

The signs common to the early stages of cancer of the cervix uteri are:—

- (1) The definite occurrence of new growth on the surface of the vaginal portion of the cervix, in the lining of the cervical canal, or in the substance of the cervix;
- (2) Friability;
- (3) Bleeding on manipulation.

(1) The definite occurrence of new growth on the portion vaginalis or in the cervical canal cannot fail to arouse suspicion. When, however, thickening of one lip or a portion of one lip of the cervix exists, the nature of the growth is difficult to determine if the mucous covering be still intact. It is then necessary to remove a portion of the affected tissue and examine it under the microscope.

(2) Friability is a sign of the greatest importance, and may be tested by the finger-nail, curette, uterine sound, or an ordinary long probe. Degrees of friability exist in early cases, depending upon the amount of interstitial tissue contained in the growth.

(3) The occurrence of free bleeding after the slightest manipulation is, when combined with friability, a valuable diagnostic aid.

Forms of Uterine Cancer.

Vaginal portion of the cervix.

- (1) *Infiltrating type.*—In this type, one lip, or a portion thereof, or even the entire vaginal portion of the cervix, is infiltrated with cancerous growth. Ulceration occurs early from the surface inwards, or necrosis may begin in the centre, and opening on the surface, lead to the formation of a deep ulcer, with undermined edges.

The growth is somewhat hard in consistence, but is still friable if tested with the probe, curette, or finger-nail.

- (2) *Papillomatous or polypoid type.*—This includes the so-called cauliflower excrescence, and is characterised by the growth from the margin of the os externum of a rounded or flattened tumour, varying in size, which may or may not have a definite stalk. It has a papillary surface, bleeds readily, and is very friable. More rarely it resembles a bunch of soft papillomata. Portions of the growth, pale red or greyish-yellow in colour, are easily detachable on examination.

- (3) *Superficial flattened type.*—This is characterised by a flattened growth on the vaginal portion which tends to spread over its surface. It is prone to early ulceration and is frequently seen clinically as an ulcer. The lip or portion affected is thickened

The ulcer has a sharply defined, raised edge, indented at places, yellowish-grey, finely granular surface, a moderate amount of loss of substance, and an infiltrated base. It bleeds readily on touch and the amount of hæmorrhage is entirely out of proportion to the amount of injury indicated. The finger-nail can detach small pieces from its surface.

Cervical Canal.

(1) *Superficial type.*—The inner surface of the cervical canal is lined by an irregular papillary growth which at first attacks the substance of the cervix superficially. As the growth increases portions of it may protrude through the external orifice of the cervical canal. When ulceration occurs the superficial portion of the growth is shed, with consequent hollowing out of the cervical canal, whilst the remainder of the periphery of the cervix is more or less thickened by infiltration. Where the external os uteri is narrow the process may be hidden, or patency of the os uteri may be produced by destruction of its margin, whilst in uteri where the os is already wide a crater-like cavity is formed.

(2) *Infiltrating type.*—The cancerous infiltration proceeds from the mucous membrane deep into the tissues of the cervix, and thus the whole cervix becomes thickened and enlarged, or the enlargement and infiltration may be limited to one or more portions of the cervical walls. Necrosis may commence on the mucous surface, or in the centre of the infiltrated area and may lead to extensive destruction of the cervical tissues.

Probably the majority of cancer cases which are overlooked are examples of disease affecting the lining of the cervical canal or the tissues of the wall of the cervix.

Cancer beginning in the cervical canal is not difficult to detect where the os uteri is dilated as in many multiparæ. The finger passed into the cervical canal feels irregular elevations or nodules from which portions may be removed. Free hæmorrhage follows this manipulation. Difficulty arises where the os uteri is not dilated and the disease is hidden. A sound carefully passed into the cervical canal may give the impression of impinging on an irregular nodular surface, or friable tissue may be removed by the curette. Free hæmorrhage following such manipulations is a suspicious sign. Thickening and hardening of the cervix may be detected by a rectal examination, which is most helpful in detecting cancerous nodules in the cervical walls, and should always be made in such cases.

Body of the Uterus.

If the vaginal portion of the cervix, the cervical canal and the cervical walls have been proved to be free from disease attention must be directed to the body of the uterus. The uterus may not be enlarged, although a cancerous growth exists in its interior. Usually, however, there is some increase in size, which in advanced cases may be considerable.

Microscopical Investigation.

In doubtful cases, if there be a suspicious hard nodule, or erosion, or ulcer on the external os uteri, a piece including a boundary of healthy tissue should be excised.

The vulva and vagina having been thoroughly cleansed, the posterior vaginal wall should be retracted by means of a speculum, and the cervix pulled slightly downwards with a volsellum. A wedge-shaped piece, the size of a pea or bean, including a margin of healthy tissue should be excised with a sharp knife.

The bleeding which follows this little operation should be stillied by the insertion of one or two sutures, or by firm tamponade with a strip of gauze. An anæsthetic is not essential. The patient should be kept in bed for 24 hours.

The tissue removed should be transferred to a small

stoppered bottle filled with absolute alcohol or methylated spirit, and forwarded without delay to an expert in uterine pathology.

Where the cancer originates in the body of the uterus or in the cervical canal, it is frequently possible by using the curette, to obtain a sufficient amount of tissue for examination without the aid of anæsthetics. If this cannot be done, it may be necessary under an anæsthetic to curette the whole interior of the uterus and cervix, special attention being paid to the region of the tubal orifices.* All fragments should be collected, including those which may have been washed out. The douche, if employed, should consist of sterilised water or a weak solution of corrosive sublimate (1 in 10,000), as carbolic acid and lysol interfere with the staining of the cells.

The fragments should be transferred to a stoppered bottle filled with absolute alcohol or methylated spirit.

If the expert's report is favourable the patient will be reassured, if unfavourable immediate operation is imperative.

The Operation.

The question of operation is best decided by the operator, who may require to examine under anæsthesia.

To Recapitulate.

- (1) Attend to all symptoms suspicious of cancer, and instruct the patient on their importance;
- (2) Examine immediately all cases of bleeding or abnormal discharge;
- (3) Make a definite diagnosis and do not wait for the disease to develop;
- (4) Urge immediate operation if the diagnosis is established.

The practitioner who diagnoses cancer in an early stage, when operation offers a probability of cure, renders a service to his patient as great as that rendered by the operator.

B.

AN APPEAL TO MIDWIVES AND NURSES IN ORDER TO PROMOTE THE EARLY RECOGNITION OF CANCER IN THE WOMB.

Cancer of the Womb is a very common and fatal disease in women, but it can be cured by operation when it is recognised early. A woman sometimes tells a nurse or midwife her ailments before she speaks to a doctor, and the nurse or midwife has then an opportunity of aiding our crusade against this terrible disease.

Cancer may occur at any age, and in a woman who looks quite well and who may have no pain, no wasting, no foul discharge and no profuse bleeding.

To wait for pain, wasting, foul discharge, or profuse bleeding is to throw away the chance of successful treatment.

The early signs of Cancer of the Womb are—

1. *Bleeding*, which occurs after the change of life.
2. *Bleeding* after sexual intercourse, or after a vaginal douche.
3. *Bleeding*, slight or abundant, even in young women, if occurring between the usual monthly periods, and especially when accompanied by a bad-smelling or watery blood-tinged discharge.
4. *Thin watery discharge* occurring at any age.

The nurse or midwife who is told by a patient that she has any of these symptoms should insist upon her seeing a medical practitioner in order that an examination may be made without delay. By doing so she will often help to save a valuable life, and will bring credit to herself and to her calling.

* Special care should be taken in using the curette as the cancerous uterus is easily perforated.

Nova et Vetera.

LEOPOLD AUENBRUGGER.

THE DISCOVERY OF PERCUSSION.

PERCUSSION as a means of testing whether walls were solid or covered hiding places, whether barrels were empty or full, and for a number of other purposes in ordinary life, must have been in use since the dawn of civilization. The whole art and mystery of the method as applied to tombs is expounded in *Edwin Drood* by Durdles to Mr. Jasper in the vaults of Rochester Cathedral:

"Now, lookee here. You pitch your note, don't you, Mr. Jasper?"

"Yes."

"So I sound for mine. I take my hammer, and I tap. . . I tap, tap, tap. Solid! I go on tapping. Solid still! Tap again. Hollow! Hollow! Tap again, persevering. Solid in hollow! Tap, tap, tap, to try it better. Solid in hollow; and inside solid, hollow again! There you are! Old 'un crumbled away in stone coffin in vault!"

It is surprising, therefore, that no one seems to have thought of using percussion of the human body as a means of diagnosis till its utility was discovered by Auenbrugger in the middle of the eighteenth century. The centenary of his death is to be commemorated by the University of Vienna on May 18th. A short account of the man is therefore opportune and may be of interest to some.

Joseph Leopold Auenbrugger was born at Gratz, in Styria, in 1722. His father is said to have been an innkeeper; however this may be, he was a citizen of credit and renown. Both he and his wife were held in high esteem for their blameless character and charitable disposition. They gave their son a solid education, and he had the advantage of growing up in a home atmosphere of the best kind. In due course he studied medicine at the University of Vienna, where he was a pupil of Van Swieten, who had sat at the feet of Boerhaave at Leyden, and on whom the mantle of that famous physician was believed to have fallen. After taking his degree, Auenbrugger settled in Vienna, but he does not seem to have been a teacher in the university. From 1751 to 1762 he was attached to the Spanish Hospital in Vienna, first as assistant, afterwards as physician. It was in 1754 that he noticed the difference of sound produced by striking the chest wall in various places. He pursued the line of clinical research thus opened to him for seven years, and in 1761 he embodied the results of his observations, "proved," in his own words, "again and again by the testimony of his own senses in the midst of labours and discouragements," in a work bearing the following title:

LEOPOLDI AUENBRUGGER

Medicine Doctoris
In Caesareo Regio Nosocomio Nationum
Hispanico Medici Ordinarii.

INVENTUM NOVUM

EX
PERCUSSIONE THORACIS HUMANI
PECTORIS MORBOS

Detegendi.

Vindobonae.

Typis Joannis Thomae Trattner, Caes. Reg.

Majest. Aulicae Typographi.

MDCCCLXII.

In the preface he says that he wished to call attention to a new method of detecting diseases of the chest which he had discovered. He goes on to say:

In making public my discoveries respecting this matter, I have been actuated neither by an itch for writing nor a fondness for speculation, but by the desire of submitting to my brethren the fruits of seven years' observation and reflection. In doing so, I have not been unconscious of the dangers I must encounter, since it has always been the fate of those who have illustrated or improved the arts and sciences by their discoveries to be beset by envy, malice, hatred, detraction, and calumny.

He confesses that there are still many defects in his work which can be remedied only by further experience and observation. After describing the sound produced by striking the chest of a healthy person in different parts, he gives a detailed account of the method of practising percussion. The thorax should, he says, be struck slowly and gently with the points of the fingers brought close together and at the same time extended. It may be noted that he recommends that while this is being done the

shirt should be drawn tight over the chest, or the hand of the operator should be covered with a glove of unpolished leather.

If the naked chest is struck by the naked hand, the contact of the polished surfaces produces a kind of noise which alters or obscures the natural character of the sound.

Had he but applied his ear as well as his hand, he would have anticipated Laennec. He proceeds to describe the dullness of the percussion note caused by the greater or less diminution of the volume of air in the chest due to compression of the lung either by effused fluid or solid growth. He proved the value of the method by experiments made with empty or partly full casks, and with a dead body, into the thoracic cavity of which fluid had been injected. He also closely compared the information yielded by percussion with the state of things found after death in cases of "scirrhus" of the lung (which he explains to be "the degeneration of the natural spongy substance of the organ into an indolent, fleshy mass"), vomica, empyema, pleural effusion, dropsy of the pericardium, extravasation of blood into the cavity of the pleura or pericardium, and aneurysm of the heart. He came near to the discovery of auscultation, for he says: "If the hand is laid over the situation of a vomica, as revealed by percussion, and the patient should cough, you will clearly distinguish the rattling of pus inside the chest. (*Streptum puris manifeste distingues in pectore interno.*)" Auenbrugger concludes with the wish: *Cedant haec miseris in solatium, veris autem medicinae cultoribus in incrementum artis: Quod opto.*

Auenbrugger's teaching fell on deaf ears; his discovery was ignored by those occupying the high places of medicine in his day, even by his own teacher, Van Swieten. The only physician of standing in his own day who appreciated the value of the discovery was Stoll, who succeeded De Haen as Professor at Vienna. The method was either confused with succussion, which is mentioned by Hippocrates, or not mentioned at all by contemporary writers. The lot which befell Auenbrugger's little book is an example of the attitude of the "superior person" towards anything new that does not emanate from his own lofty sphere, which has been one of the chief influences that have retarded the progress of medicine. It was not till the *Inventum Novum* was translated into French by Napoleon's physician, Corvisart, in 1808, that Auenbrugger's discovery obtained general recognition. But the fame thus gained by the author came too late, for he died on May 17th or 18th, 1809. It had previously been translated into French by Rozière of Montpellier, and went through two editions. But it was practically unknown till Corvisart stamped it with the impress of his great name, at the same time giving Auenbrugger the whole credit of the discovery. His wife had died a year before the French translation of his book appeared, and after that event he seems to have ceased to take any interest in the things of this life. He might have said as Johnson said to Lord Chesterfield when at the last moment that nobleman came forward as the patron of his *Dictionary*:

The notice which you have been pleased to take of my labours, had it been early, had been kind; but it has been delayed till I am indifferent and cannot enjoy it; till I am solitary and cannot impart it; till I am known and do not want it.

For notwithstanding the neglect of his *Novum Inventum* it must not be thought that Auenbrugger was either unappreciated or disappointed. His heart was in his professional work, and according to a biographer "his life was a model of honesty, philanthropy, genuine devotion to the science and art of medicine, and of kindly regard towards the poor as well as the rich." He had a large practice and was in favour with the Empress Maria Theresa and afterwards with the Emperor Joseph, who in 1784 ennobled him, bestowing upon him the title of *Elder von Auenbrugger*. This was not, however, on account of the discovery which gives him a lasting place in the history of medicine, but in recognition of his services to the public and his skill in physic. To the last he collected fresh proofs of the clinical value of percussion. He wrote some other treatises, but these are of comparatively little importance. The book on percussion was translated into English by Forbes in 1824.

He had a happy home life and had two accomplished daughters. He was fond of music and composed an opera

called the *Rauchfangkehrer*, which so pleased the Empress Maria Theresa that she asked him to write another. He declined, however, saying that he had something better to do than write operas.

Auenbrugger was interested in philosophy and general literature, and was the owner of a library which was considered large in those days.

As little is known about Auenbrugger, it is right that acknowledgement should be made of the assistance derived in the production of this brief sketch from Dr. C. N. B. Camac's *Epoch-Making Contributions to Medicine and Surgery, etc.*, and a paper entitled "Auenbrugger and Laennec, the Discoverers of Auscultation," by Dr. Edward O. Otis, of Boston, published in the *Boston Medical and Surgical Journal* of September 22nd and 29th, 1898.

INDIA IN 1907.

REPORT OF THE SANITARY COMMISSIONER.

THE report for the year 1907, which closely follows its predecessors in scope and contents, has been drawn up by Lieutenant-Colonel C. J. Bamber, I.M.S. Officiating Sanitary Commissioner with the Government of India, the statistical statements and tables, which compose more than half of the volume, being compiled by Major S. P. James, M.D., I.M.S. Certain changes have been made in the construction of these, which will be referred to below, and a few diagrams have been introduced illustrating the prevalence of plague in India and several provinces. The report consists mainly of a comment on the statistics collected during the year, relating to the general population, troops, and prisoners, with some remarks on the circumstances, climatic and otherwise, of which they are the representatives and effects. Information regarding the progress of research into the pathology and etiology of tropical diseases is scantier than in recent reports. Work done on enteric and paratyphoid fever is summarized at some length, and references are given to papers published on some other subjects. The report as a whole, while its methodical arrangement and lucid handling of figures are highly commendable, is more arithmetical and less expository than is desirable.

GENERAL CHARACTER OF THE YEAR.

The year presents a remarkable contrast to the preceding year. The main feature of 1906, as narrated in the *BRITISH MEDICAL JOURNAL* (vol. ii, 1908, p. 515), was a reduction in plague mortality, associated with an increase in the number of deaths due to fevers, bowel complaints, cholera, and small-pox, depending on conditions unfavourable to public health. In 1907, on the contrary, the excessive prevalence of plague raised the death-rates to a high level, while the ordinary causes of Indian mortality underwent considerable abatement. The climatic conditions were in some respects abnormal. The spring rainfall in Northern India was excessive, and caused damage to the early (*rabi*) crops. The monsoon rains arrived late, and were scanty in most provinces, causing shortage of the late (*kharif*) crops, which constitute the principal produce of the year.

This partial failure of crops resulted in general dearth of food, and gave rise to scarcity, almost amounting to famine, in many districts. The rains left off earlier than usual, and the months of October, November, and December were comparatively dry. The production of fevers and bowel complaints was on this account considerably diminished, and these ordinarily account for about 60 per cent. of Indian mortality. Politically the year was tranquil, and neither European nor Indian troops were employed on service either within or beyond Indian limits. Social conditions remained unaltered, and the year was exempt from catastrophes—floods, cyclones, or earthquakes—which sometimes occasion great loss of life.

VITAL STATISTICS OF THE GENERAL POPULATION.

Birth registration has been extended in Upper Burma. There are still areas in several provinces where registration has not been introduced. Registration by a professional agency has been experimentally tried in the district of Burdwan (Bengal), with the result that while the number of deaths recorded by the ordinary agency was found to be fairly accurate, the assigned causes were

largely erroneous. No change appears to have been made during the year in the agencies employed for recording births and deaths or testing the accuracy of the returns. There was a slight decline in the birth-rate of British India, from 37.80 to 37.65, the rate reckoned on the census of 1901 for the preceding quinquennium being 39.20. The highest rate (52.46) was returned by the Central Provinces, and the lowest (30.8) by Madras. The birth rate exceeded the death-rate in several provinces, and fell short of it in five, the defect in the Punjab amounting to 21.3. The death-rate of the year was 37.18, against 34.73 in 1906 and 32.91 in the preceding quinquennium. Excluding plague, the death-rate of 1907 was 32.02. The Punjab yielded the terrible rate of 62.10, nearly one-half of which was caused by plague. The Gujrat district had a mortality of 106.67, and one of its towns (Dinga) of 143.31. The lowest rate (24.3) was in Madras. Infantile mortality was somewhat lower—221.72 and 209.33 for males and females per 1,000 born, against 228.30 and 217.52 in 1906. This recession in a bad plague year would seem to suggest that infants under one year of age are not very liable to plague infection.

In all provinces the number of male infants born exceeded that of females, and in all except the Punjab the death-rate of male infants was in excess.

Details of registration in each province are given with great and, it must be remarked, unprofitable prolixity.

PREVALENT DISEASES.

Of the aggregate deaths, 53 per cent. were registered under the head of fevers, 14 of plague, 5 of cholera, 3 of bowel complaints, and 1 of small-pox, leaving 24 for all other causes. This rough classification is far from accurate, as the Burdwan inquiries and other special investigations show, but it is the best that can be got in India as yet. There was a slight rise in the mortality attributed to "fevers," but it is surmised that many fatal cases of plague found their way into this category. It is assumed that only about 25 per cent. of "fevers" are malarial. This is a conjecture founded on some inquiries conducted by Rogers and others. It is impossible to say with certainty whether in 1907 malarial fevers were in excess or defect, but the statistics of troops and prisoners indicate the latter. The highest fever rates were returned by the United Provinces (28.31), North-Western Frontier Province (27.44), Coorg (26.95), and Bengal (23.18); and the lowest, Madras (7.8), and Upper Burma (7.53). The mortality caused by kala-azar in Assam continues to decline. A report has been submitted by Captain S. R. Christophers, I.M.S., and Dr. Bentley, regarding malaria and blackwater fever in the Duars; but no information is given about the conclusions arrived at by these observers. A report has also been submitted respecting the relation between the prevalence of malarial fever and defective drainage in the Presidency division of Bengal, but the nature of it is not indicated. Reference is made to "antimalarial operations" carried out in some towns of Bengal, the Central Provinces, and Bombay, but the character and effect of them are not described. The distribution and sale of quinine in 7-grain packets is continued, but evidently on a limited and decreased scale.

The number of deaths attributed to plague rose from 356,721 to 1,315,707, the highest aggregate recorded since the introduction of the disease into India in 1896, the respective rates being 1.33 and 5.16. The Punjab heads the provincial returns with the enormous rate of 30.27; the United Provinces come next with 6.90, then follows Bombay with 5.06, and the Central Provinces with 3.18. In the remaining provinces the rates were smaller though none were entirely exempt. There was an increase of mortality in all the provinces except Eastern Bengal and Assam, Ajmere-Merwara, and Coorg, which suffered to a very slight extent. The immunity of Eastern Bengal and Assam is held to be remarkable, and worthy of special investigation. The report is silent as regards preventive measures, except that an outbreak of pneumonic plague in Darjeeling, introduced from Chupra and resulting in 7 deaths, is said to have been stamped out by "stringent measures," the nature of which is not stated. The Bombay Bacteriological Laboratory issued 620,923 doses of antipneumonic vaccine against 176,651 in 1906. Reference is made to instances of success attending the use of the prophylactic, but particulars are not given, nor of experi-

ments made in this laboratory regarding the use of rat and flea destroyers. The diagrams to which allusion has been made show the prevalence of plague in India, Bengal, the United Provinces, the Punjab, and Bombay during the years 1898-1907 inclusive. The remarkable seasonal phenomena of the disease are well brought out. A fall towards the close of the year is said to augur favourably for 1908.

There was a marked fall in cholera mortality in all provinces except Bengal, Coorg, and Lower Burma. The death-rate for British India as a whole was 1.81, against 3.05 in 1906. Bengal had a rate of 4.07, Eastern Bengal and Assam of 2.58. Madras of 2.2, and Lower Burma of 1.42; the remaining provinces were below the average. Statistical facts relating to the prevalence of the disease are given in great detail, but no additional light is thrown on causation, pathology, or treatment. There was a slight decline in the mortality caused by dysentery and diarrhoea, the death-rate for India being 1.25, against 1.35 in 1906. Small-pox mortality was also lower—0.46 against 0.48. The deaths of children under 10 years of age amounted to 69.70 of the total number; the high rate of 9.15 was recorded in the town of Barpeta, Assam, the head quarters of the Mahaparushiyas, "who on religious grounds object to vaccination." It is stated that their objections are yielding to persuasion, and that small-pox is diminishing. In the Punjab the death-rate of towns in which vaccination is compulsory was 0.93, compared with 1.72 in towns in which it is optional.

THE GAOLS.

The improvement in sickness and death-rates is progressive, and indicates an advance in "the arrangements for counteracting the influences of adverse climatic conditions and for preventing the spread of communicable diseases." The average number of prisoners was 107,675—2,407 less than in the preceding year. The death-rate, including the Andamans Settlement, was 18.51, the lowest on record. Excluding the Andamans, where convicts live under special conditions, and where the death-rate was 23.59, the rate for Indian gaols was 17.72, against 19.27 in 1906 and 21.12 in 1901-5. There was also a reduction in the rate of admissions into hospital—624 against 658. As usual, the chief causes of sickness were ague, dysentery, abscesses, ulcers and boils, and diarrhoea; and of deaths dysentery, phthisis, and pneumonia. There was a decline in the admission-rate of intermittent fever and a slight rise in the death-rate, the figures being 190.2 and 0.79, against 207.2 and 0.72 in 1902. The admission-rate and death-rate of remittent fever were unprecedentedly low, but the term does not indicate any definite type, and is to be supplanted in future reports by the entry "pyrexia of uncertain origin." Quinine prophylaxis is eagerly resorted to in all provinces, but the method employed varies considerably, and information regarding results is scanty.

Antimalarial measures are cursorily alluded to. Dysentery has never been less prevalent, and has never caused a lower mortality in the gaols of India than during 1907. The rates were 67.9 and 2.57, against 78.9 and 3.25 in 1906. There were fewer admissions and more deaths from diarrhoea, which is said to be more common and fatal among old and infirm prisoners. There was an increase in respiratory admissions and deaths, the mortality from pneumonia rising from 2.55 to 2.90. On the other hand, there was a satisfactory decline in phthisis prevalence and mortality, the rates falling from 8.8 and 3.21 to 7.5 and 2.74. Early detection and special open-air treatment are strongly recommended, and measures to this end are being adopted in many gaols.

The statistics of "anaemia and debility" are about the same as in previous years. There was a decrease in admissions and deaths from cholera (140 and 55 against 187 and 105), also from small-pox (65 and 6 against 82 and 9). There was an explosion of cholera in the Coimbatore Central gaol, in which 74 admissions and 32 deaths took place. The outbreak was considered to be water-borne. Plague, as might be expected, gave increased admissions and deaths (59 and 30 against 19 and 8). Most of the cases occurred in the prisons of the United Provinces, Punjab, Bengal, and Bombay. Sixty-five cases with 10 deaths were attributed to enteric fever, against 102 and 18. There was a reduction in the prevalence and mortality of influenza. Thirteen cases of cerebro-spinal

fever occurred, 11 of which were fatal. Only 2 admissions from Mediterranean fever were registered. Fifty-six cases of epidemic dropsy with 5 deaths were returned, and 107 cases of beri-beri with 12 deaths. These diseases were made the subject of special investigation, and considerable doubt still prevails as to the differential diagnosis. An inquiry was also carried out by Captain Foster, I.M.S., regarding the prevalence and mortality of dysentery in Bengal gaols. "A proposal has been made to establish at Kasauli a subsidiary gaol to accommodate prisoners bitten by rabid animals." The returns only show 7 admissions from dog and jackal bites, with no death. Thirty cases of snake bite were admitted, two of which were fatal. Over-crowding still exists in many gaols of all the provinces; but efforts are being made to remedy this and many other sanitary defects.

EUROPEAN TROOPS.

The strength of the European army in 1907 was 69,332. Of this number, 11,689 were located in hill stations, and 3,515 in hill convalescent depôts, 1,755 were marching, and 1,099 stationed at Aden. The health of the troops was excellent and the rates of admissions, constantly sick and deaths lower than in any preceding year. They were 756.4, 46.4, and 8.18, against 870.8, 51.4, and 10.43 in 1906, and 983.7, 60.7, and 12.11 in the quinquennium 1901-5. The invaliding rate was also lower. The decline in these rates was due to a decrease in all the chief causes of sickness and mortality. There has been a change in military administration. There are now two armies, northern and southern, in place of three commands and two divisions as formerly. This necessitates a recasting of health statistics, and renders a comparison with previous years difficult. This is the fourth alteration in the distribution of the army which has taken place since 1877, a circumstance which justifies the creation of definite and permanent geographical areas for purposes of statistical grouping and comparison. These, which are indicated on the map accompanying the report, possess the additional advantage of associating in the aggregate places similarly circumstanced as to physical and climatic characters.

There was a slight increase in the prevalence of influenza, which affected mostly troops stationed in the Indus Valley. Only 3 cases of cholera occurred, 2 of which ended fatally. This is the lowest number on record, excepting in 1899, when there were only 2 cases. There was also a decrease in small-pox, the admissions being 30 against 87, and deaths 1 against 4; 16 of the cases were in men who had not been successfully revaccinated. There was a great decrease in the prevalence of intermittent fever, the admission-rate having fallen from 176 to 152, and the number of deaths from 15 to 9. There was also a decrease in the admissions registered as remittent fever, a term which will not appear in future returns.

The admissions from "simple continued fever," though fewer than in 1906, were much more numerous than in previous years, owing to the more exact diagnosis of malarial cases. The term is to be discontinued, its place being taken by the formula "pyrexia of uncertain origin," which will include remittent fever as well. Antimalarial measures, including the prophylactic use of quinine, the use of mosquito nets, drainage, filling of hollows, destruction of larvae, "marching into camp" (the segregation of Europeans), sulphur fumigation, etc., are diligently carried out, and the intramuscular injection and prolonged administration of quinine undoubtedly minimize relapses. Only 5 cases were diagnosed as Malta fever. There has been a very satisfactory reduction in admissions and deaths from enteric fever, the rates being 13.1 and 2.77, the lowest recorded since 1888 and 1885 respectively. The subject is discussed at great length from the points of view of bacteriology, causation, and prevention. The importance of taking special action with reference to bacillus carriers is strongly insisted on. There is a standing committee on enteric fever which collects information and issues recommendations, and it is evident that every possible effort is being made to reduce the mortality caused by this disease in the European army of India. Only 8 cases of plague occurred with 3 deaths. A curious outbreak of multiple neuritis occurred at Poona, the causation of which is obscure. Dengue was much less prevalent, and bilharzia has nearly died out. The prevalence of phthisis was much the same as in previous years, and cases of pneumonia were

fewer, but deaths slightly more numerous. There was a decided abatement in dysentery admissions and deaths, and also in abscess of the liver. The fall in venereal diseases is progressive, and is attributed to moral influences.

There was less sickness and mortality among officers, the death-rate falling from 17.53 to 7.71. There was also considerable reduction in the sickness and death-rates of women and children. Altogether the record is one of improved health, due no doubt to the more favourable conditions of the year, but also, it is to be hoped, to more enlightened and strenuous sanitary efforts.

NATIVE TROOPS.

The strength of the native army was 126,392. Of this number 9,030 were marching, 1,509 in Aden and other places outside India but in the Indian command, 749 in Colombo, 734 in Singapore, and 3,050 in China; 22,710 were located in hill stations. The admission-rate, 628.9; constantly-sick-rate, 21.7; death-rate, 6.27; and invaliding-rate, 5.76, were the lowest on record. The death-rate does not include deaths on sick leave or furlough; if these be added, the rate is raised to 8.51, slightly higher than that of the European army. There was a reduction in all the principal causes of sickness and mortality. There was a slight rise in influenza, which was specially severe in Quetta. Cholera fell from 94 cases and 62 deaths, to 34 and 24, and small-pox from 79 and 4 to 48 and 5. There was a decrease in admissions and deaths from ague and remittent fever, also in admissions from "simple continued fever," many cases registered as such being probably malarial. Twelve cases of kala-azar occurred, the diagnosis being confirmed by splenic or hepatic puncture. Typhus fever is rare among native troops, but 24 cases were returned as such with 4 deaths. Of these, 23 occurred in three regiments stationed at Peshawar. The infection appears to have been derived from mule corps drivers, who contracted the disease in the surrounding villages.

Twenty-six cases of relapsing fever were admitted of which 3 died. The spirillum was discovered in all of them. There were no cases in the European army. There was a rise in admissions and deaths from enteric fever, which numbered 182 and 44. The cases occurred in 84 regiments located in 53 stations, and in only 10 were more than 3 cases admitted. The increase is held to be due to more accurate diagnosis. The number of recorded cases of Malta fever also increased; 62 were diagnosed as such with 2 deaths; of these, 30 occurred in Rawal Pindi—28 of them in the 35th Sikhs. The blood of 39 goats which supplied milk to the Sikhs was examined by Captain Brayne, I.M.S., in the Kasauli Institute, and it was found that that 11 of them agglutinated the *Micrococcus melitensis*. Notwithstanding the increased prevalence of plague in India there was a diminution of admissions—85, with 56 deaths against 147 and 83 in 1906. In 66 stations where the disease was present the troops escaped. The admissions from scurvy and phthisis were about the same, but the death-rate of the latter was lower, amounting to 0.33 against 0.20 in the European army, and 3.07 in gaoles. The death-rate of Gorkhas was 1.03. Efforts are being made to improve their barracks. Pneumonia and other respiratory diseases were more prevalent and fatal, especially in Upper India. Dysentery and diarrhoea were less prevalent, and there was a fall in the admission-rate from venereal diseases, which only amounted to 14.7. There were only 7 admissions for beri-beri, 6 of them in Aden. The admissions for guinea-worm (472) were mostly in Central India. There were none in the European army, but 438 in the prisons.

VACCINATION.

There was an increase in the number of vaccinations performed during the year; greater in revaccinations than in primary operations. The percentage of success in both classes was higher, as also the number of operations done by each vaccinator. The rate per 1,000 of census population was 36.07, a rise; and the ratio to estimated births 44.36 per cent. The cost of each successful case was about the same. Each province has its *dépot* for the manufacture of vaccine except the Central Provinces, where lymph is prepared at the head quarter stations of districts. Inoculation is still practised in some parts of Burma and Assam.

The prevalence of plague interfered in many places with vaccination. A machine invented by Major Entrican, I.M.S., for filling tubes has been used with satisfactory result.

SANITARY ADMINISTRATION AND WORK.

No change of importance took place during the year in sanitary administration. The appointment of a sanitary engineer for the province of Eastern Bengal and Assam has been sanctioned. A sum of Rs.6,000 has been sanctioned in Burma for the erection of model sanitary works. The details in the report indicate sustained effort in prosecuting and maintaining sanitary works, and local bodies are spending money freely on current sanitary purposes. There has been a falling-off in the sale of manure in the Punjab, and sewage farming in Madras has not been attended with success.

MISCELLANEOUS.

The number of pilgrims who left Bombay for the "Haj" was the largest on record. Special precautions were taken to prevent the exportation of plague. The disease broke out at Jeddah in January, but did not attain large dimensions or spread, and information regarding the health of the pilgrims is scanty. Interesting summaries are given regarding the work done in provincial laboratories, which have been reorganized and strengthened and are doing excellent work. A course of lectures with practical instruction has been arranged for hospital assistants in the Bombay bacteriological laboratory, and in the King Institute of Preventive Medicine instruction has been given to medical officers, sanitary inspectors, vaccinators, plague inspectors regarding the subject matter of their duties. Brief reference is made to special inquiries conducted during the year regarding plague, enteric fever, dysentery, malaria and blackwater fever, lathyrism, and gaol dietaries, and a list is given of scientific publications issued during the year. Mr. W. W. Haffkine, C.I.E., is now engaged in scientific research in the laboratory attached to the office of the Sanitary Commissioner with the Government of India.

LITERARY NOTES.

We regret to announce that the appearance of Lord Lister's *Collected Papers*, which were ready for publication, will be slightly delayed by a serious fire which broke out in the binding house of the Oxford University Press, near Aldersgate Street Station, on May 7th, and did damage estimated at £30,000. All the bound copies, except one or two, have been destroyed or damaged. Fortunately a number of unbound copies escaped destruction, but all the lithographic plates were burnt, and will have to be reprinted. We understand that special efforts are being made at the printing works at Oxford to replace the volumes that have been destroyed.

A new volume will be added this week to Messrs. Methuen's "New Library of Medicine." It is by Dr. Harrington Sainsbury, Senior Physician to the Royal Free Hospital, and is entitled, *Drugs and the Drug Habit: Chapters on the Dynamics of a Remedial Particle*.

The April number of *Janus* contains an article on malaria in Tropical America and among Indians by Dr. Otto Eftertz of the Isthmus of Tehuantepec, Mexico, which, apart from its scientific interest, contains some interesting anthropological and historical notes. He says the natives themselves recognize that they suffer from malaria in a far more malignant form than foreigners. This they explain by the assumption that the latter have "stronger blood." When told it is because the foreigners take quinine and they do not, they do not believe it. They refuse to take quinine except in extremely small doses, as they say it hurts them. Their own healers preach the same doctrine, the argument being "Quinine is hot, fever is hot." According to Indian pathology and pharmacology, the primary classification of diseases is into "hot" and "cold": in accordance with this remedies are divided into "hot" and "cold." The first law of Indian therapeutics is that the disease and remedy must be of different denomination—the opposite dogma to *Similia similibus curentur* of the homoeopaths.

Therefore they treat malaria with "cold" purges, cold drinks, cold irrigations of the bowels, and so forth. The favourite internal drug is a nut called *cedrón*, powdered and mixed with *mescal*, a native whisky which is supposed to be "cold," whereas other alcoholic drinks are hot. If they do take quinine, they go at once into cold water so as to counteract the heat of the quinine. A term of insult for a regular doctor is, "He is a quinine doctor." They have the greatest belief in patent "pills of life," "pink pills," "pills of health," etc.; quinine pills, however, they reject by whatever name it is attempted to disguise them. Indians do not consult regular doctors; they only buy from them patent medicines which most of the regular practitioners sell. On the general question of malaria, Dr. Effertz says that, limiting the observations to natives, it might be said Africa has practically no malaria while the disease is rife in America. On the other hand, if only Europeans are taken into account, it might be said that Africa is full of malaria while America is practically free. He suggests that the reason why American malaria is milder as far as Europeans are concerned than African is that up to comparatively recent times Europe was a great field of the disease and, therefore, Europeans possess a fair amount of hereditary immunity—not enough to protect them against the strong African variety, but sufficient to enable them to resist the mild American disease. He explains the greater relative malignity of malaria as it affects Indians by the fact that in America malaria has been introduced or at any rate generalized in comparatively recent times. In Europe malaria is younger than in Africa, but older than in America. This, according to Dr. Effertz, explains why the disease is to Europeans far more malignant in Africa than in America. It explains why Europeans die where Africans thrive, and why Europeans thrive where Indians die. Recent historical researches have shown that in the Old World malaria has been introduced or generalized in historical times in countries where it was thought to have always existed. Dr. Effertz argues that if in the Old World with its frequent wars and great movements of population malaria could remain comparatively localized for many centuries, it is reasonable to believe that in America, where such movements were very limited, malaria—if we refuse to admit its recent introduction—may have remained localized. The history of the Conquest shows that at least in Mexico, in the isthmuses of Tehuantepec and of Panama, and in Peru there was no malaria when the Conquistadores landed. Dr. Effertz holds that in a country where malaria was endemic the Conquest would have been equally impossible. It must not be forgotten that the Conquistadores had no quinine. In Mexico we read of fevers only in the expedition to Honduras, where Cortes nearly died. Nor can there have been malaria in Panama. No malarial disease is recorded among the conquerors of Peru, and in Peru itself there was no malaria. To discover the cradle of American malaria we must find a place where Indians resist malaria just as well as Africans and where Europeans resist it less than Indians. That place has not yet been looked for. Dr. Effertz further supports his thesis that malaria is of comparatively recent importation in America by the fact that, although quinine is extracted from a tree of American origin, native healers knew nothing of its febrifuge properties. These were discovered by European doctors. The native Indian healers are well acquainted with plants having medicinal properties. They discovered every plant which is of any use in syphilis, their remedies for that disease having repute even among the white. These remedies are generally family secrets; they are certainly some improved decoction of Zittmann. In Indians syphilis is extremely benign, whereas malaria is extremely malignant. It is the extreme benignity of syphilis in Indians which persuades Dr. Effertz that the disease is American in origin, and the skill of Indian healers in treating the disease is an additional argument for this view. On the other hand, the extreme malignity of malaria in Indians is a strong argument in favour of the recent introduction of malaria among them, and this argument is corroborated by the helplessness of Indian healers in dealing with the disease.

Surgeon Fernand L. de Verteuil, R.N., has kindly called our attention to an instance of false concord (*Treponema*

pallidum), which recently escaped our vigilance; it should, of course, have been *pallidum*. He goes on to say:

This organism was first called by Schaudinn and Hoffmann, its discoverers, the *Spirorhynchus pallidus*—the name by which it is still most generally known. They, however, on account of certain morphological and other characteristics, subsequently gave it the name of *Spironema pallidum*, which was finally changed to that of *Treponema pallidum*. As this is Schaudinn's last nomenclature, it should be the term used in referring to the specific germ of syphilis.

We take this opportunity of calling attention to the contempt shown by so many writers on parasitology for the elementary rules of etymology. They insist on writing *aclylostomum* or *aclylostoma*—for they are not consistent even in their heresies—and justify these atrocities by the fact that they are in accordance with the rules adopted by the Nomenclature Committee of the International Congress of Zoology. On this we need only say that the fact only proves that mixed congresses can produce monsters. The word is not only hideous to the eye, but has not a shadow of justification in the Greek language, from which it is presumably derived. The Greek word for something bent or hooked is *ἀγκυλος*, and there is no such word as *ἀγκυlostoma*. In the spelling adopted by the Congress of Zoology, *g* is a very bad transliteration of a *γ*, which would be nasal before *k* or *χ*, and the *ch* is wrong, because the Greek is *h*, and not *χ*. The proper form is *ancilostoma*, or *ankylostoma*. To lessen the risk of mispronunciation, the form adopted by this JOURNAL, after full consideration as to the best English rendering of the Greek original, is *ankylostoma*, and it may not be out of place to state that the word is neuter; therefore *Ankylostoma duodenalis* should find no favour with gods, men, or printers. According to Stiles, *aclylostoma* has been "emended" six or eight different times; we venture to say, in the words of Hamlet, that it should be reformed altogether.

In the sixth volume of the *Life of Richard Wagner* (Kegan Paul, Trench, Trubner and Co., Limited, 1908, pp. 452) Mr. William Ashton Ellis discusses the causes of the ill-health of the composer of *Tannhäuser*. Nordau bluntly writes him down a degenerate; but if we accept Lombroso's teaching, which of us will scape that stigma? Mr. Ashton Ellis accepts the theory of eyestrain, and quotes Dr. George M. Gould, who has included Wagner among his crowd of distinguished sufferers from astigmatism. Dr. Gould's view is that the composer's constant headaches, colds, and attacks of erysipelas were part of his disease, but his gloomy and pessimistic outlook on life and frequent longing for death were due to the same cause. His love of walking was but Nature's way of relieving the tired eyes. According to this theory we are all more or less sufferers from eyestrain. But in Wagner's case we have some definite clinical evidence from an ophthalmologist who actually saw the patient. This is Sir Anderson Critchett, whose testimony is as follows:

The great composer complained to my father that he was suffering from severe frontal headaches, insomnia and inability to work for more than short periods without distress. At my father's request I tested and examined Herr Wagner's eyes, and found that in each he had a dioptric of myopic astigmatism. He was both astonished and delighted when he saw music through the spherocylindrical glasses which corrected his error of refraction, for the notes, lines and spaces were seen with a cleanly cut definition which up to that time he had never known. After his return to Germany he sent us several kind and grateful messages, and the assurance that the unpleasant symptoms had been much relieved. In the ardour of composition the glasses not infrequently came to grief, and I was amused to receive a request that I would order *six* pairs to be sent to Bayreuth.

In another letter Sir Anderson says:

I feel sure that the degree of astigmatism was the same in each eye, but the vision of the two eyes was not identical, though there was no very marked difference.

Sir Anderson cautiously adds:

Expert opinion will doubtless vary respecting the extent to which the error of refraction exerted a sinister influence on the life of the great composer, but none can deny that it may have been an important factor in the troubles to which you allude.

Whatever may be thought as to the eyestrain explanation of Wagner's sufferings, Mr. Ashton Ellis's readers must be grateful to him for a very interesting addition to Wagner literature. The book shows abundant signs of careful study and research, and barring certain eccentricities of style, is eminently readable.

PRACTICE OF MEDICINE AND SURGERY BY UNQUALIFIED PERSONS.

THE following circular has been addressed to medical officers of health by the Local Government Board in England:

LOCAL GOVERNMENT BOARD,
WHITEHALL, S.W.,
23rd April, 1909.

SIR,

I am directed by the Local Government Board to state that their attention has been drawn by the Lord President of the Council to the following resolution adopted by the General Medical Council during its recent session:—

That the General Medical Council being of opinion that the present Medical Acts do not sufficiently enable persons requiring medical aid to distinguish qualified from unqualified practitioners, and that it is contrary to the interest of the public that medical and surgical practice should be carried on with impunity by persons holding no recognized qualifications, requests the Government to take steps for the appointment of a Royal Commission to inquire into the evil effects produced by the unrestricted practice of medicine and surgery by unqualified persons.

Before deciding what steps, if any, should be taken in the matter, the Lord President is desirous of obtaining some definite information on the points referred to in the resolution, and has approached the Board on the subject.

With a view, therefore, to assisting the Lord President, the Board would be glad if you would, as briefly as possible, state:—

(a) Whether the practice of medicine and surgery by unqualified persons is assuming larger proportions in the district for which you act as Medical Officer of Health; and

(b) The effects produced by such practice on the public health of the district.

The Board would be much obliged if they could be furnished with the information asked for at an early date.

I am, Sir,

Your obedient Servant,

S. B. PROVIS,
Secretary.

To the
Medical Officer of Health.

A correspondent informs us that to this communication he returned the following very pertinent reply:

In answer to your inquiry as to the practice of medicine and surgery by unqualified persons.

There is no unqualified practice in this district except by chemists who practise both medicine and surgery by prescribing and dispensing their own prescriptions and also by dressing or otherwise advising as to the treatment of various injuries.

Neither practice is for the good of the public health, and I have known cases in which the delay thus caused has been not only serious but even fatal.

Medical News.

MISS FLORENCE NIGHTINGALE entered on her ninetieth year on May 12th. She was made a member of the Order of Merit in 1907—the only woman who has received that honour—and received the honorary freedom of the City of London in the following year.

THE McGill University of Montreal intends to confer the honorary degree of LL.D. on Dr. George A. Gibson, of Edinburgh, at the Medical Convocations on June 9th. Dr. Gibson gave the inaugural address of the Medical Faculty of the McGill University on September 22nd, 1908, his subject being *The Limits of Knowledge*.

THE course of four lectures on statistical methods in physiology and medicine to be given at the London Hospital Medical College by Mr. Major Greenwood, jun., M.R.C.S., L.R.C.P., will commence on Friday, May 21st, at 4.30 p.m., and will be continued on June 4th, 11th, and 18th. The lectures are open to students of the University of London, and others on presentation of their cards.

DR. STUART McDONALD, F.R.C.P.E., who has been appointed Professor of Pathology in the College of Medicine, Newcastle-on-Tyne (the Medical School of the University of Durham), and Pathologist to the Royal Victoria Infirmary, Newcastle, has, since 1900, been Lecturer in Pathology in the School of Medicine of the Royal Colleges, and in the School of Medicine for Women, and Pathologist to the Royal Edinburgh Hospital for Sick Children, and to the Chalmers Hospital.

THE Harben Lectures of the Royal Institute of Public Health will be delivered this year by Professor R. Pfeiffer, Director of the Hygiene Institute, Breslau, in the Lecture Room, 37, Russell Square, W.C. The first lecture, on the

importance of bacteriolysins in immunity, will be given on Monday, June 21st; the second, on endotoxins and anti-endotoxins, on June 23rd; and the third, on the problem of virulence, on June 25th. Each lecture will be given at 6 p.m., and persons interested are invited to attend.

THE twelfth meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act, 1902, was held at the Privy Council Office on May 12th, Mr. Almeric W. FitzRoy, the Clerk of the Council, in the chair. The following witnesses attended: Mr. Sydney Stephenson, M.B., F.R.C.S.; Dr. Sidney Barwise, County Medical Officer of Health, Derbyshire, on behalf of the Public Health Committee of the Derbyshire County Council, and on behalf of the Midland Medical Union; Mr. Walter Schröder, Deputy Coroner, County of London, Central District.

THE number of students who have entered at the London School of Tropical Medicine this session is 50. The rapid increase in the number is straining the accommodation of the school to its utmost limits. The committee is therefore unable to accept any more students for the present course; in special cases, however, application may be made to the director in case a vacancy has occurred. There is still room for students who desire to take out the advanced courses. The next session commences on October 1st. Among those who have entered for the present session are 12 officers of the Colonial Service, 7 of the Indian Medical Service, 1 of the Medical Service of the Royal Navy, 1 in the service of the Rangoon Municipality, and 1 in that of the Australian Government. There are 24 private students, besides 2 from the missions, and 2 medical officers of the United States Army.

ALMOST ever since its institution the Army Council has shown itself commendably anxious to secure co-operation between the military and civil branches of the medical profession, whenever such is likely to promote the efficiency with which the duties of the Army Medical Service are carried out. The latest instance of this policy is an appointment recently made at the principal military hospital, that at Millbank. This hospital is the head quarters of the Army Nursing Service, and in connexion with members of its staff, and in the case also of soldiers' wives, questions of gynaecology sometimes arise requiring expert advice. In consequence the post of Consulting Gynaecologist has been brought into existence, and has been filled by the appointment of Dr. W. S. A. Griffith, of St. Bartholomew's Hospital.

THE physician or surgeon approaches art so far as it affects the human frame from an anatomical standpoint, and in the Academy Exhibition this year the nude is a good deal in evidence. In some pictures it must be supposed the artist intends the figures to be looked at from afar, since the outlines are not definite. Many others display a very high standard of anatomical knowledge. In fact there are only two pictures the figures in which are seriously open to criticism from the anatomical point of view. In "Once Upon a Time" (339) the muscles forming the lower part of the neck are too prominent, while in "The Dragon Fly" (511) the lower limbs are much too long in proportion to the trunk. Mr. Benjamin Clemens's group, "The Expulsion" (1649), is an excellent example of how a correct knowledge of anatomy adds force to sculpture: by anatomy is meant not merely a correct knowledge of the distribution of the muscles of the body. Adam is represented with an expression of mingled apprehension, alertness, and determination. The whole pose of his body intensifies this expression; every limb is in a position of activity, every muscle stands out sharp and distinct under the skin ready to act at any emergency. In the figure of Eve by his side there is apprehension, but mingled in her case with a looking back rather than forward; her body, too, is in a position of activity, and the great skill that the artist has shown lies in his representation of this same position of activity in the two forms, male and female, side by side. In the woman the contraction of the muscles fails to disturb the smoothness of the skin, and it is only at the knees that they can be seen, while the joints are less acutely bent in contrast to the male figure. Many of the portraits of ladies in evening dress represent strained position of the shoulders, which are held somewhat high, the scapulae being pulled back so that their vertebral borders are almost touching one another. It is not a peculiarity of one artist or one sitter, for it occurs many times (24, 26, 148, 322, 404, 403, 720). This habit of position will be handed down to succeeding generations. One other point needs mentioning in a notice of anatomy at the Academy: it is the speaking likeness of Mr. William Pearson (612), the Prosector to the Royal College of Surgeons.

British Medical Journal.

SATURDAY, MAY 15th, 1909.

THE DOCTOR AS A VICARIOUS PHILANTHROPIST.

THE position in which medical men are placed when called to attend urgent cases of labour or street accidents, with the certainty that in most cases they will receive no remuneration, is fast becoming intolerable. Two cases that have recently occurred in the north have forcibly emphasized this. In the first case, that of Dr. Morgan of West Hartlepool, a medical man has been pilloried in the public press for not attending a street accident when called on, though he was not the police surgeon, and despite the fact that having been refused payment by the police authorities in other cases to which they had called him, he had notified them that he would not in future respond to their summons. No notice was taken of his explanation that he was not informed of the serious nature of the case, nor had he any opportunity of attending the inquest to rebut the statements made about him. The case, as will be seen from a report of a special meeting of the Hartlepoons Division published in this week's SUPPLEMENT, has excited a good deal of feeling in the local profession, and it is unanimous in protesting against the unjust criticisms of which Dr. Morgan has been the object. In the second case, Dr. Wright, of Tow Law, near Bishop Auckland, was called on late at night to go to a labour case. The husband of the patient stated that Dr. Wright demanded that his fee should be guaranteed, and sharp words ensued. Dr. Wright denies that he refused to go, and says that the husband deliberately turned away. Another doctor was summoned, and on his arrival found that twins had been born, but that the mother had died from heart failure through exhaustion. The coroner described it as a "lamentable case," but reminded the jury that the impression that a doctor is a public servant and bound to go when called was incorrect, as a doctor was entitled to be paid or to know when he would be paid. The jury returned a verdict that death was due to heart failure arising from exhaustion from want of proper attention at confinement, and a rider was added to the verdict that it was "unwise of doctors to raise the 'question of fees.'"

Two facts stand out prominently in these cases: In the first case it is clear that Dr. Morgan was grossly ill-treated in not being afforded an opportunity of being at the inquest where his conduct was in question; and in the second case, the coroner, though he correctly stated that the common impression was wrong, yet exceeded his duty in accepting the rider to the verdict. The wording of the rider is somewhat curious. It might bear the meaning that doctors would show more wisdom not to mention fees, but to give some other reason for not attending. That might, perhaps, show more worldly wisdom and might prevent some irritation, but it leaves out of account the element of conscience, of which medical

men are not quite devoid. What the jury probably meant, however, but hardly liked to say after the coroner's remarks, was that doctors ought to go to such cases whenever summoned without question, and trusting to chance for payment afterwards. That is the popular view, and seems to be the view of most municipal authorities, if not of Parliament itself, if we may judge by the Midwives Act.

Now, it may be conceded that if in a particular case the question were simply that a doctor, knowing that refusal to attend would involve suffering or danger which he might prevent, yet refused to go on the sole ground that his fee was uncertain, he would fairly be deemed guilty of inhumanity. In the words of the Poor Law Commission, "the physical condition of the patient should be the first consideration," and "neither the promptitude nor the efficiency of the treatment should depend on whether the patient can pay for it." That applies to a public medical service, and only perhaps in a second degree to private practice; still every member of the profession, including Dr. Morgan and Dr. Wright, will readily agree to it. So far the popular impression is right; so much common humanity demands; but when all this is granted, we have only faced half the question. For it is obvious that the primary responsibility for making proper provision for medical attendance in confinement cases rests on the patient or her husband; if they fail for any reason to make such provision the duty belongs to the community as a whole and certainly not to any one section of it, and it is neither reasonable nor just for the community to attempt to throw its own duties on the shoulders of any particular class, such as the medical profession. This is freely acknowledged in the case of paupers, who are clothed, housed, fed, and medically treated at the expense of the State, even though their poverty be their own fault. So far is this carried as regards medical treatment that paupers are actually better off in this respect than the working classes who, by dint of hard struggling, manage to keep themselves just above the level of pauperism. The anomaly is accentuated when we find that the State actually accepts a theoretical responsibility for the latter class but in numerous directions fails to make provision for practically discharging its responsibility. The Midwives Act is a forcible case in point. The whole Act is a practical acknowledgement that it is to the present and the future interest of the community that parturient women should be properly cared for. The conditions in which medical aid should be obtained are carefully prescribed, but the means for obtaining such aid are omitted. The State sets out to do a generous thing, but its generosity turns out to be a cheap generosity at the expense of the medical profession. It is not paupers who are in question; they are already fully provided for under the Poor Law. It is that large class just above the level of pauperism, women who can just afford by careful saving to lay by a midwife's fee, but if any emergency occurs, are totally unable to pay the doctor's fee in addition. For some time after the Act came into force it was thought that, though the Act itself made no provision for medical assistance, counties and county boroughs would arrange, with the consent of the Local Government Board, to pay medical fees in midwives' cases under Section 133 of the Public Health Act of 1875. More than six years have elapsed, and of the 62 administrative counties of England and Wales not a single one has availed itself of that section, while of the 74 county boroughs only 3, Cardiff, Liverpool, and

Manchester, pay such fees. Newcastle and St. Helens did actually commence, but they have ceased and left the duty to boards of guardians. The hardship suffered by this large and deserving class of women was fully recognized by the Local Government Board in its circular of July, 1907, in which boards of guardians were advised to pay a fee under the Poor Law Amendment Act of 1848 to any medical man attending a midwife's call under the Midwives Act. Of the 640 Poor Law unions, less than 100 have made any response, and even of these many have either refused to pay for any but paupers, or have attempted to restrict the work to their own district medical officers, or offer a totally inadequate fee of 10s. 6d. for operative interference, or else hedge round the payment with such conditions that it is practically certain that in most cases the doctor will be no better off than before. Thus the advice of the Local Government Board, which was followed up by similar advice from the Privy Council Office in February, 1908, has been simply ignored, and all the beneficent intentions frustrated by most boards of guardians. The Local Government Board seems absolutely helpless to do anything more, however much it might wish.

In this state of things what must medical men do? If they refuse to attend these cases without guarantee of a fee they are called brutal and inhumane. If they do attend, they are voluntarily taking on themselves a burden which the Local Government Board acknowledges ought to be borne by the community; they are doing State work without State pay, and, as experience shows, if they will do it they may go on doing it indefinitely. There can be no wonder, then, that in Essex, Norfolk, parts of the East End of London, Salford, and numerous other places medical men have notified the authorities and the coroners that they will refuse to attend until a fee is guaranteed, as they object to their feelings of humanitarianism being exploited by the local authorities. It is impossible to condemn this attitude in spite of its deplorable results, and even though the Midwives Act is thereby in danger of becoming a failure. The whole cost to the State, if all local authorities were compelled to pay a fee, would be trifling compared with the benefits to the community. In 1907 the cost in fees in Manchester only amounted to £247, but the result has been that parturient women in Manchester may be confident of obtaining medical aid with the least possible delay. It is not suggested for one moment that patients who can pay for themselves should not be compelled to do so, but the authorities must see to that: it has been done in Manchester, where a donation of a few pounds a year to the Charity Organization Society procures the needed information as to the ability of patients to provide for themselves.

The same state of affairs exists with regard to medical attendance in street accidents. In London, Manchester, Salford, and a few other places there are definite arrangements made for payment on fixed scales of fees to medical men called by the police to attend cases of accident or sudden illness occurring on the streets. But in by far the greater number of towns there is no provision at all. The authorities simply evade their responsibility by trusting that the humanitarian feelings of medical men will compel them to do the work for nothing.

It is impossible that this condition of things should continue. Humanity will always claim sacrifice, and will always get it from the medical profession. It is freely admitted that a man's responsibility for helping others increases with his ability to help, but it can

never be conducive to the welfare of the citizens that any one section of the community should be systematically exploited for the rest. Sydney Smith said that philanthropy in practice generally meant that Jones thought Smith should do something for the relief of people in distress, and this view is generally held by the public in respect of medical practitioners. It is high time that even coroners and their juries should realize that, however convenient it may be to be charitable at another man's expense, the doctor cannot live if he is to be regarded as a vicarious philanthropist.

THE PROBLEM OF UTERINE CANCER.

It is exactly a third of a century since Freund, on January 30th, 1878, removed by the abdominal route a uterus which showed "tubular carcinoma of the 'portio' with isolated carcinoma of the fundus" from a woman whom he was able twenty-six years later to present to a congress at Breslau. In the interval many technical problems have been debated and much experience has been accumulated by surgeons and pathologists, and both technical problems and experience have contributed to the general recognition of the fact that many cases of uterine cancer have been transferred to the category of curable disease. With cancer of the fundus the curability is even now almost universal, but with cancer of the cervix a large number of recurrences still arise. Of these recurrences, almost all are found to begin in the scar of the old operation, and are to be interpreted as due to the operation having been made through already affected tissue. The surgeon has learned that if women are to reap the full benefit of the wider range which the abdominal operation has given, the cases must go to him earlier.

Of the patients who at present reach the operator three in every four have passed through the hands of their family doctor, and of these a very appreciable proportion have been kept under treatment for some time without any local examination having been made. So long as this is the case the medical profession cannot divest itself of the charge of being responsible for some part of the incurability of cancer. The greater part of the delay in cases seeking our aid is, however, due to the folklore of the menopause, which makes irregular bleeding an ordinary and transitory phenomenon, and leads the woman herself to postpone a call for assistance. The problem of getting our cases of uterine cancer in an early stage is, therefore, substantially that of creating a new folklore among womankind, so that they shall no longer treat irregular bleeding as normal at the change of life, and shall not wait for pain and wasting before they come to seek assistance with the fear of a commencing cancer.

How the education of women is to be accomplished is a question which has for some time engaged the attention of gynaecological societies, and, on the recommendation of the Obstetric Section at the Annual Meetings at Exeter and at Sheffield, the Council of the British Medical Association appointed a special committee to report on the matter. Under the chairmanship of Dr. F. J. McCann, this committee has gone very fully into the matter, and has prepared a report whose recommendations were approved at the last meeting of the Council. In common with the other societies, the committee has recognized that there are two available channels through which women may be approached—the general practitioner and the two now

organized services of midwives and nurses, who, themselves women, have at times an earlier access to the ears of other women than the medical profession itself. To each of these channels the committee has prepared a special entrance in the form of an appeal which in these days can be made available through the professional press. Both appeals appear elsewhere in this issue, and copies were forwarded last week to medical and nursing papers throughout the British Empire.

The appeal to medical practitioners is a somewhat elaborate document, in which a detailed account is given of the symptomatology of uterine cancer and the methods of examination, special emphasis being laid on the uprooting of what is merely an ancient leechlore, that cancer is a condition to be recognized by pain, severe bleeding, and cachexia. One fact of which the full import may not at once be recognized is that in this appeal is laid down very distinctly a doctrine of professional responsibility which would make failure of the practitioner to insist on local examination almost a malpraxis.

The second appeal, to Nurses and Midwives, is much the most simple and direct document of the kind which we have seen prepared for circulation in any country. It would be no serious task to commit the whole of it to memory, and it seems well adapted to the knowledge which both nurse and midwife may be expected to acquire in the course of their training. The committee has ended each appeal with a just recognition of the essential merit of each factor in the course of a woman to the cure of her uterine cancer, the nurse who sends her to a doctor, the doctor who recognizes the condition, and the surgeon who removes it.

The growth of a folklore is slow like its decay, and it will be interesting to see how soon with modern ways we can adapt that of cancer to the new capabilities of its treatment.

THE BUDGET AND MEDICAL AUTOMOBILISTS.

IN the article dealing with the Budget last week the fear was expressed that the statement by the Chancellor of the Exchequer in introducing the Budget could not be held to imply an intention to make any rebate of the new petrol tax in the case of medical automobilists. This fear proves to be correct, for, in reply to a question put to him in the House of Commons by Dr. Cooper, Mr. Lloyd George said that medical men would not be entitled to the rebate. The profession, therefore, is now aware precisely how matters at present stand, and is in a position to take steps accordingly. Arrangements have already been made to ask the Chancellor of the Exchequer to receive a deputation representing the British Medical Association; and there are some indications which augur well for its success. Thus, a more recent question put to him by Mr. Joynson-Hicks (Manchester) Mr. Lloyd George met, not by a definite refusal to reconsider the point, but by a statement to the effect that he was at present disposed to doubt whether a rebate to medical men in respect of petrol as well as car licences would be justified. There have been indications, too, that the House at large would view a rebate with approval. Even from the Government benches, for instance, came a suggestion that in default of a rebate the tax on petrol would seem almost to amount to a special income tax on medical men. Furthermore, the case for a rebate is undoubtedly strong in itself. Since,

as has been already recognized by Mr. Lloyd George, there are considerations which make it right to put a lower tax on the cars of medical men, it would be unreasonable to cast those considerations aside when dealing with the article which is essential to the use of those vehicles. A great deal of support for the case for a rebate could doubtless, too, be derived from the individual experience of medical motorists. A good many instances in point are supplied in the letters published this week (p. 1208). The calculations in the notes on the subject last week were purposely based on an estimate of the minimum additional expenditure which the new taxes would throw upon medical motorists. As was there indicated, a distance of 5,000 miles is certainly not an overestimate of the distance annually travelled by a medical man on his professional rounds. There is no doubt, indeed, that far greater distances are often travelled by the very men who can least bear any additional expenditure—men whose net returns from practice are small and whose use of cars confers a great benefit on the scattered communities among whom they work. The distance of 5,000 miles, it may be said, was mainly adopted because in these columns and in motor journals it has frequently been used as a convenient unit on which to found estimates of the annual expenditure of medical men on motor cars. Similarly, as regards petrol consumption, it is undoubtedly true that medical men whose work lies chiefly in towns cannot expect to secure the same mileage per gallon as if they were running from point to point. Furthermore, by no means all medical men use, or should be expected to use, cars so small as those of the 8-h.p. type; nor are all cars of that description as satisfactory in respect of petrol economy as those on which the estimate of 25 miles was founded. Hence, apart from the natural objection of medical motorists to be handicapped by further additions to their inevitably heavy expenditure, it would be easy to show that unless a rebate is granted the tax may create hardships of a kind probably quite unanticipated by Mr. Lloyd George. These considerations will doubtless be borne in mind by the deputation which is to wait on him, but to ensure success it is absolutely essential that each man should also act for himself. There are points which constituents can bring out with much better effect in conversations with individual members of Parliament, or in private letters addressed to them, than by a deputation, and every medical motorist should lose no time in communicating with the member representing his district.

INSURANCE FOR MEDICAL MEN.

AS was pointed out a short time ago, the results of the work of the Medical Insurance Committee, established jointly by the BRITISH MEDICAL JOURNAL and the *Lancet*, prove how valuable such an agency is to medical men. The field covered by the agency established by the Committee is steadily widening, and it is clear that medical men are beginning to some extent to realize the advantages offered to them, especially in insuring against personal accidents. The agency is conducted on thoroughly business-like lines under the superintendence of Mr. Guy Elliston, 429, Strand, London, W.C., from whom full particulars can be obtained. With the exception of a small amount, absorbed by clerical expenses, the whole of the profit of the agency has gone to the insurers. The members of the Committee in giving their time to the work are actuated by benevolent motives, as it is intended, when the volume of the business of the agency has increased, as it ought to increase, that the surplus shall be devoted to the assistance of the benevolent agencies of the profession. Possibly

not every person who takes out an insurance policy of any kind is aware that there is a considerable difference between the sum which he pays by way of premium and the amount which enters the coffers of the company which insures him. In other words, there is, in the conduit between the pocket of the insured and the insurer, a leakage in the shape of agency fees. The ordinary insurer cannot avoid this leakage—this payment of moneys over and above the true equivalent of the risk accepted by the insuring company—but it is otherwise with the policy-seeker who deals with the Medical Insurance Committee. In his case the leakage is abolished, for a pipe is provided which conducts back into his pocket the greater part, while any surplus will be used for the benefit of his unfortunate brethren. The *modus operandi* is of the simplest kind: the Committee itself acts as an agent, hands out policies, and retains in its own hands the percentage of all the premiums received by it on behalf of the company for which it acts as agent. This percentage, however, it does not keep itself, but when expenses have been paid hands back a part to the insurer himself. The forms of insurance which the Committee undertakes at present are in respect of personal accidents, of fires, and of burglaries, as well as life insurance and insurance against that liability which was thrown upon the medical profession in common with all other employers of domestic and other labour by the Act of 1906.

UNQUALIFIED PRACTICE.

WE reproduce in another column a circular letter which the Local Government Board in England issued recently to medical officers of health. It will be remembered that at the last meeting of the General Medical Council a report from the Unqualified Practice Prevention Committee was presented by Dr. Langley Browne, chairman, and that on his motion, seconded by Dr. Latimer, the Council adopted a resolution pointing out that the present Medical Acts do not sufficiently enable "persons requiring 'medical aid'" "to distinguish qualified from unqualified practitioners," and that it is contrary to the interest of the public that medical and surgical practice should be carried on with impunity by persons holding no recognized qualifications, and requesting the Government to appoint a Royal Commission to inquire into the evil effects produced by the unrestricted practice of medicine and surgery by unqualified persons. The circular letter quotes this resolution, and states that the Lord President before deciding how to act desires to obtain information as to whether the practice of medicine and surgery by unqualified persons is assuming larger proportions and as to the effects produced by such practice on the public health. It may perhaps be assumed that the Local Government Board is already in possession of information establishing the notorious fact that the Medical Acts are ineffective to attain the expressed purpose of the Legislature, otherwise we would have been disposed to criticize the terms of the first of the two questions which it has addressed to medical officers of health; the point is far wider than the terms of the first question. It is not merely whether unqualified practice is increasing, but whether the Acts are ineffectively drawn to prevent it. The point is perhaps covered by the second question, because the words "such practice" should be taken to refer not to the matter of increase but to the effect of the practice as it exists, whether it be increasing or not, and no doubt medical officers of health will not have overlooked this distinction. As will be seen, one medical officer of health, who has already replied to the inquiry from the Local

Government Board, has drawn attention to the evils arising from the great prevalence of counter prescribing—that is to say, unqualified medical practice by chemists and druggists. There is reason to believe that the term "counter prescribing" does not adequately indicate the whole extent of the evil, for there are cases on record in which chemists have not only prescribed over the counter, but have paid medical visits to sufferers in their own homes. As the Local Government Board and the Lord President of the Council are in an inquiring frame of mind, it might perhaps be well that the Divisions of the British Medical Association should take the opportunity of laying before one or other office information in their possession as to the prevalence of unqualified practice and the injury which it inflicts on the public health.

THE DEVELOPMENT OF TRYPANOSOMES IN TSETSE FLIES.

AT the meeting of the Royal Society on May 6th, the Secretary announced that Colonel Sir David Bruce, who is in charge of the Sleeping Sickness Commission at present in Uganda, had telegraphed to the Society on April 3rd that the Commission had confirmed Kleine's observations on the period during which the tsetse fly is capable of transmitting a trypanosome infection. A letter was received on April 30th from Sir David Bruce, dated Mpumu Chagwe, Uganda, April 3rd, confirming the telegram, and stating that the Commission had "repeated Dr. Kleine's experiments with *Trypanosoma gambiense* and *Glossina palpalis*, also with a 'trypanosome of the dimorphon type and the same 'tsetse flies, and found the flies infective after sixteen, 'nineteen, and twenty-two days.' Thus confirmation quickly comes to Dr. Kleine's original work, and the fact that trypanosomes develop in tsetse flies may now be said to be established. This discovery must of necessity, as was pointed out in the JOURNAL of May 1st, have a considerable influence on the prophylaxis of the human disease, because once the cycle in the fly is completed, it may be capable of transmitting infection for long periods afterwards, just as with the *Stegomyia fasciata* and yellow fever. The *Bulletin* of the Sleeping Sickness Bureau, No. 6, to be issued this week, will contain an article discussing the significance of the observations and pointing out that they should lead to experiments to find out what species of tsetse flies can serve as true hosts for the various species of pathogenic trypanosomes, whether the trypanosomes contained in the blood of an infected person are able at all stages of the disease to infect *G. palpalis*, what is the nature of the cycle of development, and in what part of the fly it takes place. It is noted that in Kleine's experiment the trypanosome transmitted came from a country infested by *G. morsitans*, but yet underwent development in *G. palpalis*, a fact which raises the question whether, since more than one species of the tsetse fly can serve as true host for an animal parasite, why not also for *T. gambiense*, the parasite of man? We have no doubt that experiments of the nature indicated will shortly be undertaken, or have already been commenced. Dr. Kleine, who is director of the German organization against sleeping sickness in German East Africa, is to be heartily congratulated on the brilliancy of his original observations.

ALCOHOL AND PROPRIETARY REMEDIES.

TO many students of the minuter records of the doings at the Courts of mediæval monarchs it may seem that, so far as recorded conversations are concerned, the only wise men were the official jesters. They certainly had the advantage of being able to sail

safely somewhat nearer the truth in their conversation than other people; but in any case it is an old observation that many a wise thing is said in jest. As an instance in point we quote a recent saying of one of the professional jesters of the *Globe* with reference to the new imposts on alcohol.

"The public do not realize," says a doctor, "that in the production of almost all medicinal products alcohol is a *sine qua non*." Can it be that this accounts for the vast popularity of some patent medicines?

The right way to reply to the question would be to borrow an American phrase and say "Got it in once," for the position actually is precisely what is humorously suggested by the querist. Time after time it has been shown that where alcohol prohibition laws are in existence the consumption of certain proprietary remedies rises and falls automatically in precise ratio to the severity with which the prohibition laws are enforced. Nor is this difficult to understand, because though many proprietary remedies are by no means pleasant to take, some of the less unpalatable are little more than disguised alcohol. A proportion of the consumers are perfectly aware of their contents, and buy these concoctions because they provide an easy way of getting the alcohol which they cannot otherwise buy. Nor does this happen only in the prohibition States of America, for in other countries there are persons who would not like to be known as alcohol drinkers, while their constant reliance on a medicine bottle merely excites sympathy. On the other hand, the majority of purchasers of these remedies buy and use them in absolute innocence; they take them because they find themselves stimulated thereby, and are unaware that the stimulation is merely alcoholic. The fact that so many proprietary remedies consist mainly, if not entirely, of coloured, sweetened, or otherwise "doctored" alcohol is not, of course, the only objection to them; but it is one strong objection, and it would be a step in the right direction if vendors of proprietary remedies which contain a considerable proportion of alcohol were obliged to affix to the bottle a full statement of their contents in plain language.

THE ROYAL SOCIETY'S CONVERSAZIONE.

THE first of the two conversazioni given annually by the Royal Society was held at its rooms in Burlington House on Wednesday, and was, as usual, well attended. Several exhibits dealt with radium and the rare gases of the atmosphere. Mr. Francis Fox exhibited samples of pitchblende from Trenwith mine, Cornwall, and specimens of uranium bromide, uranium oxide, and other constituents. Sir William Ramsay showed the properties of liquid radium emanation. Professor J. Norman Collie had an exhibit of perfectly pure neon, which, when enclosed in a tube with mercury and shaken glows with a bright orange-red colour, even at ordinary pressures. If the gas is enclosed with mercury in a silica tube and the mercury boiled, the mercury vapour glows bright green at pressures almost as high as the atmosphere. The most interesting exhibit in this connexion, however, was Mr. T. H. Laby's demonstration of Professor E. Rutherford's method of counting the alpha particles—a marvel of ingenuity and accuracy. By an electrical method a deflection of an electrometer is obtained as each alpha particle, derived in this instance from uranium, passes into a cylinder. Dr. Bashford showed for the Imperial Cancer Research Fund a series of diagrams illustrating recent advances in knowledge of cancer, and a specimen of the kangri, the portable fire basket worn in Kashmir, the use of which leads to cancer of the skin of the abdomen. Dr. Waller

reproduced an experiment first shown by him in 1878 illustrating the electric conditions of the heart, and showing how the different orientation of the heart in man and in quadrupeds may be demonstrated electrically. The eccentric condition in man was illustrated by the fact that the electric phenomena were best shown by dipping the two hands into two beakers of saline, whereas in the dog the best results were shown by immersing a fore and a hind leg respectively. This method of studying the heart's action is not expected to have extensive application in medicine, but it is hoped that it may prove of value in giving additional evidence in certain cases. Mendelism was represented directly only by a case of *Abraxas grossulariata* (currant moth), illustrating sex-inheritance (Mr. L. Doncaster). An account of the results established by the study of the males and females of this variety is given in Professor Bateson's book reviewed in this issue. Incidentally the subject of heredity was touched upon by Professor Karl Pearson, Mr. E. Nettleship, and Mr. C. N. Usher, by some plates illustrating Mendelism and by some pedigrees of man contributed by the Eugenics Laboratory. Other exhibits of interest were some optical instruments, including a new form of optometer for the examination and measurement of defects of vision (Professor W. F. Bassett); the stages in the life-history of the tick, *Ornithodoros moubata*, responsible for the transmission of tick fever (Lieutenant-Colonel W. B. Leishman); and a microscopic section of the aorta of King Menephtah, traditionally regarded as the Pharaoh of the Exodus, showing senile calcification (Mr. S. G. Shattock). Two demonstrations were given in the lecture room, the one by Dr. A. E. H. Tutton, F.R.S., the revelation of crystal structure by polarized light, and the other by Dr. Hans Gadow, F.R.S., of a series of photographs of the scenery, animals, vegetation, and native tribes of Mexico.

THE LOCAL GOVERNMENT BOARD AND PUBLIC VACCINATORS.

EVEN those members of the profession who consider that too much regard is given by medical organizations to questions of remuneration cannot cavil at the action of the Association of Public Vaccinators in seeking an opportunity to be received in deputation by the President of the Local Government Board on the subject of grievances mentioned in the correspondence published in this issue of the *JOURNAL* (p. 1215). The deputation is refused a hearing because the "points" have been brought before the President's notice, and received his consideration. This is poor comfort for those who have received unjust treatment at the hands of boards of guardians, as the grievances remain unabated, and no assurance is given that any steps will be taken to prevent the recurrence of the harsh treatment narrated in the correspondence. If, as is stated by the Local Government Board, there is no power, under the existing law, to prevent the scandals mentioned, a speedy reformation or amendment of the law is strongly indicated. Public vaccinators are subject to the supervision and stringent inspection of the Local Government Board, and common justice demands that they should be protected from vindictive and spiteful treatment such as these cases demonstrate. The reply from the Local Government Board contains a repetition of a principle which the Board professes to recognize. It is asserted that where the offices of district medical officer and public vaccinator are held together the remuneration for each office should be proportioned to the duties of the office. In practice, however, appointments have been sanctioned by the

Board which violate and disregard this principle. Where the holders of these appointments have fought for the establishment of this principle their efforts have been in vain, and in some cases they have suffered dismissal, receiving no assistance or encouragement from the central authority. Concerning fixity of tenure the Board relieves itself from responsibility by shrinking behind the excuse—no power. It has, however, the power to seek such power. Moreover, the position is somewhat contradictory. By the simple process of an Order, known as the Dewsbury Order, the Board recently conferred fixity of tenure on the public vaccinator at Dewsbury. Right comes to all at last, though often slowly, and the battle with the apathy of the department where the just claims of medical officers are concerned must evidently be waged over and over again.

LONDON'S SMOKE PALL.

THE Public Control Committee of the London County Council has had under consideration the question of smoke abatement and the advisability of the Council's powers being strengthened in the matter. At present, apart from the special cases of locomotives on railways and on roads, the County Council has power to act only in default of a borough council. The borough councils, in their turn, find it difficult to obtain convictions under the Public Health (London) Act, 1891, because the sections which confer powers upon them contain so many qualifying words. The only provision of real value is that dealing with "black" smoke, and this limitation of an effective section is unfortunate, as very frequently smoke which is not black is emitted in such volume as to cause a serious nuisance. The Committee advises that legislation should be promoted next session to provide for the deletion from Section 24 of the word "black," to bring the premises of the Government, local authorities, and statutory companies under the operation of the Act, and to enable the County Council to deal with smoke arising from premises outside the boundary and drifting into London. The Committee points out that the million domestic chimneys in London are responsible in winter for probably one-half of the smoke nuisance. Some of the densest fogs have occurred on days when most of the business premises have been closed, and Dr. W. N. Shaw, of the Meteorological Office, states that London loses half its sunshine in winter and one-sixth in summer owing to the density of the smoke pall. A bank of smoke has been observed to rise to a height of 3,000 or 4,000 ft. and to be carried by the wind in a sunlight-obscuring trail for fifty miles. Abolition of the open fire in favour of the closed stove system while it would undoubtedly result in a purer external atmosphere, would sacrifice much of the fresh air within doors, for which open fires, by providing a good deal of ventilation, are largely responsible. The Committee looks for a reduction of domestic smoke from the adoption of firegrates which secure better combustion of coal, and to the growing use of gas and electricity for heating and cooking. The report concludes with the suggestion that yet another subject should be added to the day school curriculum—that instruction should be given to the children in the principles of combustion, so as to make them grasp the fact that smoke is not inevitable, but commonly results from the wasteful use of fuel. With the object of educating public opinion the Committee recommends that power be sought to spend not more than £500 a year in the advancement of measures for the abatement of smoke nuisance. The Finance Committee, however, places a check upon the reforming zeal of the Public Control

Committee. It "views with apprehension" any proposal for obtaining additional powers which might involve the Council in increased expenditure of an unascertained amount.

TREATMENT OF SCHOOL CHILDREN.

WE noted a short time ago that the London County Council had made arrangements with the Queen Victoria Jubilee Institute for Nurses for the treatment of school children suffering from suppurating ears. The scheme provided that there should be given to children found by the school doctor to be suffering from the affection cards intimating that treatment should be provided, the parents being instructed to obtain medical advice. The cards prescribed the form of treatment to be given, the medical practitioner being required only to sign the prescription. To this a footnote was added, as follows: "It must be distinctly understood that the London County Council will not be responsible for the treatment prescribed or given." We learn that the card has now been amended in consequence of a communication sent to the Council by the Metropolitan Counties Branch of the British Medical Association,¹ suggesting that the method of treatment prescribed on the card should be omitted and blank lines substituted, on which the full instructions of the medical practitioner in charge of the case could be inserted. The Branch also took objection to a request to the parent to "consult your own doctor, or take the child to a hospital for advice," on the ground that the children should not be referred to institutions founded and maintained by charity, but if not under the care of their own medical attendant should receive care under a regular medical service. The card was altered in accordance with both these suggestions, and the Council, taking warning from the case to which attention was recently called in this JOURNAL, has substituted words less calculated to frighten parents. The notice as it now runs reads as follows: "This child is reported as having discharging ears. As careful nursing treatment is often efficacious in such cases, the Council is prepared," etc.

THE PREVENTION OF MALINGERING.

A CIRCULAR has been issued recently by the Scottish Mine Owners' Defence and Mutual Insurance Association, Limited, which at first sight would appear to be quite uncalled-for, and apt to be construed as an interference with medical practitioners in the due performance of their duties. The circular referred to—which, we presume, is issued to mine owners insured with the association mentioned—states that its directors have agreed to appoint inspectors to supervise workmen in receipt of compensation for accidents, with the view of seeing that those who have received slight injuries should not remain idle longer than is necessary, and also to assist the medical officers—we presume of the association—in reporting as to the condition of workmen who have received more serious injuries. Three inspectors have already been appointed, all ex-police constables, and the directors propose to appoint others. The circular further states that the directors contemplate making arrangements for further medical supervision in Fife and Clackmannan. It will be noticed that the inspectors already appointed are to assist the medical officers in reporting on the condition of the workmen. One would like to know what is exactly meant by medical supervision by the inspectors. There is much to be said in favour of a system of inspec-

¹ Metropolitan Counties Branch. Medical Inspection of School Children. SUPPLEMENT, BRITISH MEDICAL JOURNAL, April 3rd, 1909, p. 155.

tion, provided it is judiciously carried out. Those medical practitioners who have had much to do with employees in railway companies and industrial works, and especially referees under the Workmen's Compensation Act, must come across many cases of slight accidents in which workmen go on drawing compensation pay long after they are able to resume work. In such cases we can see no objection to the system of supervision as indicated in the circular referred to. An intelligent and tactful lay inspector would prove of much assistance to the medical officer of companies or the official referee; he would be able to report what the medical man could not do, or even be asked to do—namely, the movements of the injured workman. This may seem a system of private detectives, but the matter must be looked at from the employer's point of view as well as from the men's. Workmen who take the advantage of the Workmen's Compensation Act for trivial injuries, which they are apt to magnify, and who, had this Act not been in force, would never think of absenting themselves from work, are a charge upon the industry of the country, which has to be paid out of the earnings of the industry concerned; that is to say, in the long run, partly out of the wages of honest workmen, and partly out of the profits of the employer. With reference to cases of more serious injury, we do not think the services of a lay inspector meet the case; in such cases nothing but skilled advice should be taken. For this purpose the association should employ medical inspectors.

SPIRITUAL MINISTRATIONS IN THE SICK ROOM.

At the annual meeting of the subscribers and friends of the Border Counties Home for Incurables, held recently, the Bishop of Carlisle, who presided, is reported to have said that the clergy were often hindered by doctors in their ministrations to the sick. He went on to say that he was one of those who were thoroughly persuaded that God worked by means in every department of life, and to neglect the means which He had provided in the way of surgical skill and medicinal remedies was really to get out of co-partnership with God in the matter of the art of healing. He was speaking in the presence of a tried medical friend, with whom he had never spoken upon the subject he was about to mention; but he most firmly believed that during the last thirty years a considerable part of the medical profession had been to blame for the development of what he thought was mis-called Christian Science. No doubt they had acted from the highest motives, but it had been quite a common thing for medical men to place difficulties in the way of the clergy and ministers of religion attending sick beds. He dared say that these medical men had met clergy and ministers of religion who had often seemed to be not wise, not calm, not helpful in the sick room, and had found that their ministrations had been medically injurious; and, therefore, on the ground of the medical injury which had been wrought by imprudent and unwise representatives of religion ministering to the sick, they had put great difficulties in the way of the clergy attending to the sick, especially when the latter were in a state of fever and high excitement. Now he was one of those who believed that there was no influence so wholesome, so quieting, so tranquillizing, so remedial, or so medicinal upon the sufferer as the influence of religion brought wisely and calmly to bear upon the sufferer. He was not talking in the air, but he spoke of what he knew, when he said that it was a very great wrong to put any hindrance in the way of an approach to true, calm, and deep religion at the bedside of the affected and suffering. Dr. Henry Barnes, who spoke after the bishop, said, with regard to

Christian Science, that he did not think that all the members of the medical profession were to blame in the respect that had been mentioned. Personally, he had never interfered between a clergyman and a patient, and whenever a patient had expressed a desire for a clergyman to be called in he had always been willing for the latter to come in and give that sympathetic help which the patient required. For our own part, while fully agreeing with the bishop that the influence of religion on those who have faith in its teachings is likely to be beneficial in sickness, we do not think that patients in "a state of fever and high excitement" are in a condition favourable to its operation. But on the general question we believe that the profession at large shares the sentiments expressed by Dr. Barnes. Spiritual ministrations are outside the doctor's sphere of action; his duty is to do the best he can for the bodily welfare of the sufferer under his charge. He has no right to keep the minister of religion out of the sick room unless either from the condition of the patient or from his knowledge of the personality of the clergyman there be reason to fear that his influence is likely to be the reverse of beneficial. There are tactless parsons just as there are inconsiderate doctors. If the patient is in danger of death, the consolations of religion should never be refused him if he or those about him wish for them. With such matters the doctor has as little right to interfere as with the arrangement of the patient's worldly affairs.

THE INDIAN MEDICAL SERVICE.

SOME recent events have produced a feeling of serious apprehension among the officers of the Indian Medical Service. The first of these events is a dispatch, dated December 11th, 1908, from the Secretary of State to the Government of India, stating—according to an abstract published in that country—that he has decided that the time has now arrived when no further increase of the civil side of the service can be allowed, and when a strong effort should be made to reduce it, gradually extending the employment of civil medical practitioners recruited in India. The Government of India is instructed to consider what appointments can best be filled in this way, and in future no appointment is to be made in succession which would involve an addition to the cadre of the Indian Medical Service. We have not had an opportunity of perusing the dispatch, the text of which has not hitherto been published in this country, but there is a fear that it may foreshadow a great reduction in the number of district civil officers. On the other hand, this is not what the abstract of the dispatch—which alone has so far been published—says, and it may not be the intention of the Secretary of State. We understand that his dispatch was a reply to one from the Government of India containing proposals for the building up of an independent medical service in India, to which the well-qualified and best class of native Indian university students should be appointed. It is hoped that this plan may be carried out without affecting the popularity or rights of the Indian Medical Service, but as we have said, we feel that judgement must be reserved until the text of the dispatch has been published. The other matter which has caused anxiety is the appointment of Lieutenant-Colonel C. D. Lukis, I.M.S., Principal of the Medical College in Calcutta, a very excellent officer of twenty-nine years' service, over the heads of all the administrative officers, surgeons, generals and colonels, and over several lieutenant-colonels selected for promotion, to succeed Sir Gerald Bomford as Director-General of the Indian Medical Service. There is a strong feeling that in the interests

of the service no officer should become Director-General who has not had at least a year of military administrative work, and a similar or even longer period of civil administration.

EXOPHTHALMIC GOÏTRE.

In a recent issue of *Ophthalmology*, Dr. Baker has discussed in a very practical manner the future of patients suffering from exophthalmic goitre. It had been asserted that as soon as the disease has been diagnosed the thyroid should be removed: and Dr. Park in a paper on the subject read at Cleveland, seemed to think that unless thyroidectomy were done the patient perished miserably. Baker at the same meeting said that the only fatal case he had seen had died under the surgeon's knife. This remark roused so much opposition that he was led to look up and tabulate all the cases at his disposal. Of 50 cases, 44 still lived and none of those dead died from the disease or its complications. Most of these cases had recovered completely. Baker expresses a strong opinion that the natural tendency of the disease is towards recovery. He finds that tinnitus aurium, though not a symptom, is apt to be aggravated in Graves's disease. Marriage and especially childbirth exerts a favourable influence. The exciting cause is a mental shock, the stress of modern life, or worry. Rest is by far the most important factor in the treatment, but hydrotherapy has proved useful. The medicinal treatment is symptomatic. The patients should be encouraged in every way to believe that they will get well.

THE LATE MR. H. L. BARNARD.

THE friends of the late Mr. Harold Leslie Barnard, whose untimely death at the age of 41 deprived English surgery of one of its most promising representatives, have resolved to publish as a memorial a volume which shall include all his contributions on abdominal surgery. At the time when Mr. Barnard joined the staff of the London Hospital in 1900, he resolved to publish such a volume, and engaged two of his former pupils, Dr. F. Wood-Jones and Mr. Stanley Beale, to prepare drawings of his specimens for the work. Death stepped in when the task was approaching completion, and his friends now propose to carry out his intention. The volume will be edited by Mr. Sherren, and his friend and pupil Dr. H. H. Bashford will contribute the biography. The drawings made are of great merit, and while they will much enhance the value of the work will materially add to its cost, which is estimated at £200. The committee which has been formed appeals to Mr. Barnard's friends and pupils to assist it liberally and promptly by forwarding subscriptions to the Honorary Secretary and Treasurer, Dr. Cecil Wall, 6, Cavendish Place, Cavendish Square, W. Should the response be sufficient, it is hoped to present a copy of the book to every subscriber, and in any case to give subscribers the benefit of a special subscription price of half a guinea; the published price of the book will be 15s.

"IN THE NAME OF THE PROPHET—SOAP!"

We regret that in a paragraph under this heading in the *BRITISH MEDICAL JOURNAL* of May 8th the "statement" of "ment of sober fact" which a medical practitioner felt "in honour bound" to make as to the virtues of a certain soap—sent to him, it would seem, by the manufacturers as a disinterested mark of kindness—the address from which the "statement" emanated was, by a copyist's error, wrongly given. It should have

been 53, not 63, Harley Street, as printed. We apologize for the mistake, but as the full name and qualifications of the grateful recipient of the soap were given, the error of a figure in the address cannot cause any confusion as to the identity of the writer of the "statement," which is published as an advertisement in *Nash's Magazine*. The complainant in this case says, "Let places, no less than persons, receive 'the credit which is their due.'" We assure our correspondent that we had no intention of robbing the highly respectable mansion from which he writes of whatever credit may be its due.

THE CREMATION SOCIETY OF ENGLAND.

THE report of the Council of the Cremation Society of England for 1908, which appears in the *Transactions* recently issued, states that the crematorium at Liverpool, which was built by the efforts of local friends of cremation, under the guidance of Mr. Alfred Holt, has been taken over by the Corporation. That body has appointed a subcommittee to manage it, of which Dr. Caton is chairman, and among its members are Mr. Alfred Holt and Dr. Nicholson, in whose hands the management, while it was a private concern, practically rested. It is further stated that the City Council of Nottingham proposes to apply for a loan to provide a new cemetery, which will include a crematorium. The hope is expressed that the proposal to build crematories which is under the consideration of other city and town councils, particularly those of Bournemouth, Bristol, and Cardiff, will shortly take definite shape. A large increase in the number of applications for membership of the society has resulted from the reduction of the subscription for life membership, and the extension of privileges to any crematorium in Great Britain. Among the persons of note whose remains have been cremated at Golders Green since 1903 may be mentioned W. E. H. Lecky, Herbert Spencer, Sir Leslie Stephen, Sir Henry Thompson (founder of the Society), Sir Henry Irving, Mr. T. H. Wakley, Mr. Thomas Wakley, Sir Richard Strachey, Sir William Randal Cremer, Archdeacon A. S. Aglen, D.D., Mr. H. O. Arnold-Forster, Madame Antoinette Sterling, and Mr. R. H. Boyce, C.B.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Medical Men and the Duty on Petrol.—On Friday in last week the Chancellor of the Exchequer stated in reply to Dr. Cooper that medical men will not be entitled to a rebate of duty paid on the petrol used in their motor cars. On Monday Mr. Joynson-Hicks asked the Chancellor of the Exchequer whether, having regard to the fact that he was proposing to place only half the additional tax upon motor cars owned by doctors for use in their profession, he would, on the same principle, give them a rebate upon the petrol they consumed. Mr. Lloyd George replied that he had already made a considerable concession to doctors in respect of the licences for their motor cars, and he was inclined to doubt whether there was sufficient reason for also granting them a rebate on petrol. In reply to a further question from Mr. Joynson-Hicks, Mr. Lloyd George said that he never liked to refuse representations from any of the interests affected by bills with which he was concerned, but it was a question of time. He would, if he could, certainly meet any deputation which was representative. Mr. Chiozza Money asked whether Mr. Lloyd George would give consideration to the fact that, as the doctor used his petrol in relation to his profession, the duty amounted to a special income tax; but no answer was returned. In reply to another question, Mr. Lloyd George declined to extend to veterinary surgeons a remission of duty on motor cars.

The Spirit Duty and the Cost of Medicines.—Mr. Lonsdale called the attention of the Chancellor of the Exchequer last week to the fact that one effect of the proposed increase of 3s. 9d. per gallon on the duty on proof spirit would be an advance in the price of many medicines, and asked whether he would consider the advisability of granting a special rebate on spirits used in preparing medicines. Mr. Lloyd George said that he had received a number of letters on this point to which he was giving careful consideration. He could not promise anything at present.

Tuberculous Milk.—Mr. Tyson Wilson asked last week with reference to a report by the Sanitary Committee of the Shropshire County Council on a complaint made by the Liverpool Sanitary Authority that tuberculous milk was being sent to that city from Market Drayton, where the cowhouses and cattle were found to be in dirty condition and one cow was affected with advanced tuberculosis, whether the cow was sold and lost sight of, and what steps would be taken by the Local Government Board. Mr. Burns replied that he had seen the report. According to that report the facts were as stated in the question. He found from the clerk to the Drayton Rural District Council that their sanitary inspector attended the auction at which the cow was sold. He had reason to suppose that it would be sent either to Stoke-upon-Trent or to Newport, and he communicated with the inspectors of both places. He subsequently received information showing that the cow had in fact been sent to Newport and slaughtered there, that it had been found unfit for human food, and had been given to pigs. He understood that the cow had been dry for a month or six weeks prior to its sale, and that as soon as it was found to be diseased it was kept isolated. After the sale the cowshed was thoroughly disinfected. There were, as stated in the question, defects in the cowshed, and the district council caused the attention of the agent of the property to be drawn to them. The defects were being remedied. The case did not seem to call for further action. The local authorities and their officers appeared to have taken all practicable steps to deal with it.

Diseased Meat.—Mr. Ffrench asked whether the inspectors at Hull found during the last quarter numbers of livers infected with parasites, such as immature tapeworms and flukes; whether out of ten plucks from Rotterdam six livers were seized in one ship, and six out of a consignment of twenty in another ship; whether, in addition, seven pig livers, one pig pluck, and calf liver were destroyed as unfit for human food; whether all this came in with the Danish Government label certifying it fit for human food; and, if so, what action it was proposed to take? Mr. Burns replied that the facts as to the articles condemned were substantially as stated in the question, except that the consignments appeared to have been contained in packages bearing labels attesting inspection by the Dutch and not by the Danish Government. He had asked to be informed of all cases in which it was found necessary to condemn certified meat such as was referred to in the question, with a view to communication being made to the foreign authorities concerned.

The Public Abattoir, Belfast.—In answer to a question last week, Mr. Birrell stated that the Belfast Corporation decided last autumn to proceed with the erection of a new abattoir, and the necessary plans had been completed. The Corporation deferred taking further action pending consideration of a report to be made by a deputation appointed to visit abattoirs in other countries. The Local Government Board understood that the report would shortly be laid before the Corporation.

Glanders in London.—In answer to a question put by Mr. Anstruther Gray with reference to the prevalence of glanders in London, Sir Edward Strachey said that the London County Council were and had been for some time past taking all possible steps to eradicate glanders in London, and it was hoped that the strict enforcement of the provisions of the Glanders Order of 1907 would prove of considerable service for the purpose. The disease was

not nearly so prevalent in London as it was a few years ago; in 1904, for instance, the number of outbreaks was 1,038, whereas last year the number was 495.

Beri-beri on the Steamship "Cardiganshire."—In answer to a question as to a death from beri-beri on this ship, Mr. Tennant said the man referred to died of beri-beri when ten days out on a voyage from Bangkok to Zandam. The cause of beri-beri had not yet been definitely ascertained, but it was probable that bad and insufficient food might predispose to the disease. He was, however, informed by the owners that the food supplied in the *Cardiganshire* was better and more abundant than the India Government scale required. The man was medically examined before joining the ship, and had been on board nearly three months; but as he developed dropsy four days after joining it was possible that he took beri-beri on board with him. He was not aware whether he had had previous sea service. No other death from beri-beri had occurred on board this vessel during the last three years.

The Cost of Vaccination in England and Wales.—In answer to Mr. Lupton, who asked for the details of expenditure on vaccination, Mr. Burns said last week that the following table gave the particulars desired, so far as it was possible to supply them. It was not practicable to apportion the salaries of medical advisers, inspectors, and other officers of the Local Government Board, who were only partly engaged in dealing with vaccination cases:

EXPENDITURE ON VACCINATION IN ENGLAND AND WALES.

Financial Year.	Remuneration of Public Vaccinators and Vaccination Officers, Costs of Prosecutions, and other Expenses Defrayed by Boards of Guardians.*	Awards to Public Vaccinators.	Cost of Production and Distribution of Vaccine Lymph by the Local Government Board.		
			Salaries and Wages of Staff.	Hire of Calves.†	Other Expenses.
	£	£	£	£	£
1834-95 ..	82,961	9,823	2,369	266	981

Cregagh District Sewage.—Mr. Devlin last week asked a question as to the delay in connexion with sewage purification in the Cregagh district, and Mr. Birrell replied that the Local Government Board had made a provisional order in compliance with the petition of the Castlereagh Rural District Council for powers to acquire land compulsorily for the purpose of providing a system of sewerage for the Cregagh portion of the district, and this order would be submitted to Parliament for confirmation during the current session. The Board would regard favourably an agreement in the matter between the council and the Belfast Corporation, but it was not within the scope of its duties to effect such an agreement.

MANCHESTER AND DISTRICT.

MEDICAL AID IN STREET ACCIDENTS.

SOME recent events have shown that it is high time that some uniform arrangements were made throughout the country for the proper recognition of the services of medical men when called to accidents or cases of sudden illness in the streets. A few weeks ago, in answer to a question in the House of Commons, Mr. Asquith stated that in London a fee of 3s. 6d. was paid for cases occurring between 7 a.m. and 7 p.m. and 7s. 6d. between 7 p.m. and 7 a.m., and also that for giving evidence about such cases in the police courts 10s. 6d. was paid if within two miles of the doctor's residence and 2s. 6d. for each additional mile, with a maximum total fee of 21s. But it appears that there is no such arrangement in the great majority of our large towns, and practically nowhere in the country districts. Hitherto authorities have simply trusted to the humanitarian feelings of medical men, and it has very rarely happened that proper medical assistance has not been readily available, even though in most places every medical man knows quite well that in three cases out of four he will never be paid for his trouble. When an accident occurs everybody is ready to run for a doctor, but it often happens afterwards that everybody, even including the patient, denies any liability. It is a fact that the police in some towns have had instructions not themselves to send for a doctor; irresponsible bystanders may do so, and the police are then not liable. It is by no means uncommon for every doctor in the neighbourhood to be called, and in a short time three or four arrive on the scene only to find that the case was a trifling one or that some other doctor has already attended to it, and none of them receive anything for their trouble, though they may have been called away from a surgery full of private patients. The public has been educated to regard services thus voluntarily given without remuneration as a right which it can claim at any time. And though a doctor may have gone to half a dozen cases which have turned out to be trifling, and for which he has never been paid, if by any chance he fails to go to a case which proves serious, he is at once branded as inhumane, even by people who would pass by an accident on the other side of the street. That this is no imaginary picture is seen from a case which has recently occurred at West Hartlepool, where Dr. Morgan, a well-known practitioner, and the last man in the town who should be charged with inhumanity, has been pilloried in the public press for failing to attend an accident in the streets. It appears that he had no intimation that the case was of a serious nature, nor has it even been proved that it was possible for him to attend, and, what is far worse, he had no opportunity of attending at the inquest afterwards to rebut charges made against him. Several cases similar to the above have occurred in Manchester and Salford, and representations have from time to time been made to the authorities. It is satisfactory to state the joint committee of the Manchester and Salford Divisions has now been officially informed by the solicitor to the town clerk of Manchester that the scale of fees paid to the police surgeons "applies also to ordinary medical men when called in by the police to cases of accident or sudden illness in the streets." This scale is 3s. 6d. for attending by day and 7s. 6d. by night, with a fee of 21s. for attendance in the police court to give evidence. The official intimation however continues:

I may add that it very rarely happens that it is necessary for the police to call in ordinary medical men, as by an arrangement with the Telephone Company the police officers can use any telephone, and by this means obtain the services of the police surgeons and horse ambulances in which to convey patients to the infirmary quicker than they could obtain the services of other medical men.

For Salford, the Chief Constable writes: "The fees payable to medical men for attending street accidents in the borough or attending court are upon the same basis as those quoted by Mr. Asquith," that is, the same as given

above for London. Tramway accidents are in a different category, the arrangement being that the Salford Tramways Claims Department will pay 5s. for first aid in any tram accident, but the claim for the fee must be accompanied by a short report of the injuries and any statement the patient may have made with respect to the accident. For first aid alone 3s. 6d. has generally been paid.

It is evident that until some similar arrangement has been made universal throughout the country, there will be constant dissatisfaction; and nothing but an organized demand for the matter to be put on a business-like footing will prevent a repetition of the unfortunate event at West Hartlepool.

WALES.

THE EBBW VALE DISPUTE.

THE Ebbw Vale dispute seems to grow more and more confused. The following paragraph, which we quote from the *South Wales Daily News* of May 4th, describes what, as far as we know, is its latest phase:

The Ebbw Vale Workmen's Doctor's Fund dispute, having existed over three years, is now as far off settlement as ever. A meeting of the Cwm and Wainlwyd section was held at the Public Hall, Cwm, on Monday evening, May 3rd, when Mr. F. Griffiths presided over a large attendance. The chairman, in his opening remarks, gave a summary of the proceedings that had taken place since the signing of the original agreement, and said that the manner in which the second ballot was taken was unfair, and was an insult to the intelligence of the voters. The ballot boxes had been carried about by persons deeply interested in the result; and while he did not attribute any unjust motive, it was nevertheless not above suspicion. It was decided to instruct the solicitor to proceed for the recovery from the fund of the money awarded by Judge Owen in the county court to the Cwm section, and that, as far as the future was concerned, that matters be left in the hands of the committee to proceed in the best and most speedy way to recover what have been incurred since, and that an injunction be applied for.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

DUNDEE AND ITS SANATORIUM.

DUNDEE has missed an opportunity of honour. For some years it has, in dealing with phthisis, pursued a policy which has developed gradually through the stages of sputum examination, voluntary notification, and the establishment of a municipal dispensary. Last autumn the medical officer of health, in his report as a delegate to the International Congress on Tuberculosis, developed a scheme for the complete management of the phthisis problem. The main provisions of this were compulsory notification, municipalization and development of the Sidlaw Sanatorium, and segregation of incurable cases. The sanatorium with its forty beds was to be handed over as a free gift, but without endowment, and the financial burdens involved were estimated to require a rate of 2d. The Convener of the Health Committee met this scheme with enthusiasm and almost too great energy, and succeeded in carrying it through unmodified up to a point at which the transfer agreement had been signed, and the transaction could be closed by securing the sanction of the Local Government Board, which had been promised in advance, and the assent of the Scottish Secretary. Unfortunately, the matter had become complicated by personal questions, and by a proposal to redress an old grievance, due to the astuteness of an ancient official, which confers on Dundee the distinction of being the only place where the health-rate falls entirely on the occupier. The new rate was to be called the sanatorium rate, and was to fall equally on owner and occupier. This evoked the hostility of certain interests which were eventually successful in expressing so much public opposition that the town council which at first passed the scheme with only three dissentients, eventually at a special meeting asked the directors to cancel the agreement. That Dundee has thrown away the honour of being the first city in the kingdom to own a sanatorium for phthisis is a matter of less serious import than the unawakened public conscience it has revealed in the process. This seems to foreshadow neglect, as, of the two other ways in which the phthisis problem may be met, being more probable than a root

and branch method of improving the conditions of housing and employment which would afford appreciable results a generation hence. Any such method is even less likely to harmonize with the visible interests of the Chamber of Commerce and the House Factors Association who have been so successful in their present agitation. One unfortunate result of the present fiasco is that it has impaired the charitable support which was hitherto given to the Sidlaw Sanatorium. The results of treatment in early cases have been excellent, and it will be a catastrophe for Dundee if such relief as the Sanatorium at present affords to the phthisical of that community is withdrawn.

A WEST AFRICAN ARROW POISON.

At a meeting of the Royal Society of Edinburgh a communication was submitted by Sir Thomas Fraser and Dr. Mackenzie, Carnegie Research Scholar, on *Strophanthus sarmentosus*. It was one of the many species of the genus *strophanthus* found in Africa. A considerable number of years ago the seeds of another species came into Sir Thomas Fraser's possession, and were fully examined in regard to chemistry and action, but as the species from which the seeds were obtained was unknown the results were not published. Many efforts had been made to obtain the flower and other parts of that plant, but for a long time were unsuccessful. Specimens of several unexamined species, however, were collected, and among them was a complete and large collection of the fruit and flower of *Strophanthus sarmentosus*, and with the materials thus obtained investigations had been made. *Strophanthus* was found over a large part of West Africa—Gambia, Senegambia, Senegal, and especially in Nigeria. Most of the material had been collected by officers of the Colonial Medical Service. These gentlemen brought under the notice of the authors of the communication the prevalence in Nigeria of the use of poisoned arrows, the main ingredient of whose poison was derived from the seed of the *strophanthus*. A large number of these poisoned arrows had been obtained by the kindness of Sir Frederick Lugard. *Strophanthus sarmentosus* is a creeper or vine. The seeds are small. Sir Thomas Fraser said that the pharmacological investigation was made with an alcoholic extract from which had been removed a large quantity of fat and other inert substances. Because of the therapeutic interest which was attached to the seed of the *Strophanthus hispidus* in the treatment of cardiac disease, the action of the product was fully examined, and the result showed that the contractions of the heart were modified by it much in the same way as by the official drug. It might be expected, therefore, that *Strophanthus sarmentosus* would also become a remedy of much importance and value.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

THE PERMISSIVE PROVISIONS OF THE TUBERCULOSIS BILL.

A STRONG deputation from the local branch of the National Women's Health Association of Ireland appeared before the monthly meeting of the Coleraine Urban Council, and with statistics and arguments urged the adoption of compulsory notification and other clauses of the Tuberculosis Prevention (Ireland) Act of 1908, which is to come into force on July 1st. Several ladies spoke, and the Chairman said that the urban council had already anticipated much of the work, and was willing to bear its share of the expense of a county sanatorium; the work of the association had its strongest sympathy, and he advised the ladies to bring pressure on the county council.

When it is remembered that on both sides the discussion was carried on by the laity, and that one side was exclusively composed of ladies, the circumstance marks an enormous advance in the education of public opinion and in public health administration.

THE Japanese Government has decided to establish five leper colonies, in which at first about 1,000 patients affected with the disease in a severe form will be compulsorily isolated. The foundation of a leper hospital at Osaka and of a home in the island Kin-Sin is also under consideration.

Special Correspondence.

BERLIN.

Boy Suicides.—Sanitation of German Health Resorts.

GERMAN psychologists and German statisticians are giving much thought just now to the subject of boy suicides, and, indeed, it is time they should do so, for, in spite of the wide publicity given to these deplorable events by the newspapers—even, perhaps, by very reason of that publicity—the wildest notions on the subject seem to prevail. Not only are fantastically high figures circulated and accepted in other countries, but in Germany itself the general belief is that the evil is increasing at an alarming rate, and that overwork and brutal treatment at school are chiefly, if not exclusively, responsible for it. The Prussian Cultus-Ministry placed at the disposal of Professor Gerhardt, a theologian of mark, and himself a school teacher, its large and carefully sifted collection of material on the subject, embracing all the higher-grade boys' schools in Prussia, and covering the twenty-nine years 1880–1908. He has now published a pamphlet with well-arranged tabular information in which the correct figures can be read at a glance. If, in spite of endeavours evidently conscientious, he has not, in some of the inferences he draws from them, been entirely able to overcome certain prejudices inherent in his profession and position, still the figures stand there, and likewise the medical reports on a large number of cases; these speak a language impossible to misunderstand. The tables demonstrate that the average boy suicides, that is, the number compared with the actual number of pupils, though it has varied from year to year, has not increased during the last twenty-nine years. That in fact, except for the year 1908, the average of the last five years has been comparatively low. For instance, in 1883 the proportion was 0.013 per cent. (17 suicides out of 129,971 schoolboys), whereas in 1906 it was only 0.0077 per cent. (16 out of 205,883), these examples being taken at random. The highest proportion, 0.0146 per cent. (20 out of 136,908) was reached in 1889; the lowest proportion, 0.0037 per cent. (5 out of 131,836) in 1882. The figures for last year (1908) were again deplorably high, 0.0124 per cent. (28 out of 224,823). Unfortunately some families resolutely refused to furnish any data or information that could have thrown a light on the suicide, and in a few cases neither family nor friends nor doctor nor teachers were able to give any clue whatever. Undeterred by these blanks in his list, Gerhardt set valiantly to work to classify the information afforded by the cases of the last ten years, a total of 170, and found mental disease, oftenest a hereditary suicidal mania, fully proved in 31 cases. The surmise may be hazarded that the families who withheld all information may probably have done so for fear of disclosing to the world similar hereditary tendencies. In 47 cases no connexion whatever was traceable between school life and the catastrophe. These were none of them backward or (apparently) in any way abnormal, nor had they undergone punishment, or been worried by ironical remarks, or insulted in any way, nor did they go in dread of examinations. They were, without exception, satisfactory, steady pupils of average powers, a few of them distinctly above the average. In one group of cases miserable family dissensions (impending divorce of the parents, illegitimacy, etc.), in another early profligacy and venereal disease with fear of its detection drove the lads to their early death. Unrequited love, à la Werther, and the sudden death of parents gave the clue for the *taedium vitae* of a few others. A few killed themselves out of pure fanfaronade ("what a stir it would make," said one of these misguided boys to a friend), and three were the result of the mysterious contagion that sometimes goes out from dark deeds such as suicide. In conclusion, Gerhardt lays the blame more on the home than on the school, on the want of psychological watchfulness at home, whether it arise from ignorance or indifference. It is, at any rate, certain that his pamphlet will remove a great part of the odium that has rested on German schools so long. Still, the fact remains that the German matriculation, being a very difficult examination—far more difficult, as is believed in Germany, than the

matriculation of other countries—the less diligent or less gifted among the boys, who feel themselves bound to go through with it, or who are kept to it by their parents, are obliged to remain in school bondage at an age when they naturally long for a freer life—that they grow stale at school, in fact. No psychologist will deny the corollary that at so critical an age, and under such anomalous circumstances, terror of not being able to pass the examination after all may largely contribute towards bringing out inherited instincts which, but for such terror, might have continued dormant.

Two days' deliberations were given to the question of obligatory sanitary arrangements in German spas and health resorts by a special committee of medical and hygienic experts. The meetings were held in the hall of the Imperial Board of Health, and members of the Board, besides delegates from the Prussian ministries of trade, and of agriculture, and from the ministries of the various Federal States, were present and joined in the proceedings. The milk supply—especially at seaside places—was one of the chief subjects under discussion, and a schedule of requirements was drawn up. Further, a motion for the obligatory formation of a sanitary committee in every German health resort was carried. The establishment of a Central Balneological Bureau in Frankfurt-am-Main was suggested, and was warmly approved by the meeting. Proper steps towards realizing the project will, therefore, be taken.

Correspondence.

THE BUDGET.

SIR,—I hope you will permit me to criticize the article on p. 1133 of last week's JOURNAL, in as far as it refers to the new tax upon petrol.

Our motor cars are an expensive necessity, not a luxury. I need not advance arguments why we should be classed in common justice with other commercial consumers of petrol.

In my opinion the amount of petrol consumed per mile run, and consequently the gravity of the new tax, has been underestimated in the article. I am prepared to grant that the average mileage may be about 5,000 per annum; it is impossible to dogmatise, but I cannot admit that 200 gallons of petrol would be the average consumption for the above mileage of an 8-h.p. car.

It is conceivable that in a sparsely-populated country district, with good roads, few gradients, and comparatively few stoppages, an 8-h.p. car might average 25 miles to the gallon, but in the case of the ordinary city or suburban doctor every one will admit that the ratio of consumption will be increased by fully 40 per cent.

Take my own case, I have an 8-h.p. car. I practise in and around a large city. I use from 350 to 400 gallons per annum; I cannot give my exact mileage, but I fancy it is not more than the average. The large consumption is due to the frequent stoppages, startings, and turnings incidental to one's routine work, and further to the fact that the car is of low power, and therefore a considerable amount of the work has to be done on second speed in traffic and side streets. When I have had to make a long run I have averaged nearly thirty miles to the gallon.

The amount I am mulcted in at present for my small car as far as taxes are concerned is:

	Per annum.
Self and chauffeur's driving licences	£ s. d.
Chauffeur's Inland Revenue tax	... 0 10 0
Car under 1 ton, Inland Revenue tax	... 2 2 0

£3 7 0

In future it appears:

Self and chauffeur's driving licences	... 0 10 0
Chauffeur's Inland Revenue tax	... 0 15 0
Car over 6½-h.p., half tax	... 1 11 6
8 gallons of petrol per week at an increased cost of 4d. per gallon (3d. tax)	... 6 13 8

£9 15 2

From the information I have been able to obtain from several professional friends, such an estimate is well within the mark. One friend who runs a 10-12-h.p. car, and whose "round" is similar to my own, uses 2 gallons a day.

I hope, Sir, that the JOURNAL will stand by the members in this new imposition by offering a most strenuous opposition to the new tax. As you point out on page 1133, it would be highly anomalous if the petrol were regarded as used for other than "commercial purposes."

In the widespread agitation from all sources against the incidence of the multitudinous proposals contained in the Budget, lies the danger that we doctors may be overlooked.

Further, I hope all medical men—for practically all are motorists or potential motorists—will without delay write to their respective members of Parliament.

The Chancellor's remission of half the licence duty was greeted with a chorus of approval from both sides of the House, and I am convinced that the "petrol tax" is due to an oversight.—I am, etc.,

Higher Broughton, May 8th. W. BRUCE BELL, F.R.C.S.E.

SIR,—It is the ascertained opinion of the medical men residing in this district who use a motor car for the purposes of their profession, that the proposed tax of 3d. per gallon on petrol will be an unfair impost upon them.

That it will be a heavier tax upon them than upon the owner whose car is a luxury is indicated by the following considerations:

1. The doctor's mileage is largest in the winter, the other's in the summer.

2. The petrol consumption of the winter months is considerably greater (owing to heavy roads, etc.), than that of the summer.

3. The continual stops and restarts considerably increase the amount of petrol used.

4. It is admitted by those road surveyors whom I have consulted that the average doctor's car, unlike the heavy, high-powered, and rapidly travelling vehicle, is not responsible for appreciable damage to road surfaces.

These contentions, which can be supported by figures, seem to show that, even if the commercial rebate were allowed, the doctor would still be paying as heavy a tax as his neighbours.—I am, etc.,

J. C. NEWMAN, F.R.C.S., M.B., B.C.

Bishop's Stortford, May 10th.

SIR,—It is probable that the tax on petrol will press more hardly on medical motorists than would be indicated in your editorial on the subject. You assume that 5,000 miles is a fair average yearly run for a medical car and the expenditure at a gallon per twenty-five miles.

With regard to petrol consumption, it must be remembered that in our work, involving as it does such frequent stops, far more petrol is used than in making a non-stop run of the same distance. Thus I have an 8-10 car which on good roads and running straight will do more than twenty miles to the gallon, but which on ordinary roads in winter, and with about twenty stops a day will average only about fifteen miles to the gallon. Again, though your estimate of sixteen miles a day may be right for men in towns with some country practice, it is too low for the country doctor, who will average more nearly thirty miles, or between 9,000 and 10,000 miles per annum. This being so, the petrol tax will tell heavily on us. I know that for myself; I consume 60 gallons of petrol a month. At an increase of 4d. per gallon brought about by the tax that means £1 a month, or £12 a year, rather a big tax on a country doctor. When we learn that there is to be a rebate for "commercial" users of petrol, but that this is not to apply to medical men, I think we should make every effort to have this injustice removed in committee.

For an injustice it is. The "commercial" user, the trader who carries goods or passengers, will, it is quite certain, in the vast majority of cases get his money back at a profit. If not he has his remedy and applies it. With us how very different is the case! Many a time when we start out to see a distant patient we know that the fee, if ever paid, will barely recoup us for expenses, and that as frequently as not we shall never see a penny. It is not equity to give the trader a rebate and to withhold from those who may have to work at a loss from quite other than a commercial motive. I suggest that each medical man interested should write or see his member of Parliament and endeavour to get this injustice remedied.—I am, etc.,

Cupar Fife, May 9th.

C. E. DOUGLAS.

SIR,—Is it not proper for the British Medical Association to take action with reference to the proposed tax on the breathing spaces of towns—those, at least, that are in private hands? The proposal reminds one of the old window tax, in that it inflicts a penalty on the supply of fresh air.—I am, etc.,

Tunbridge Wells, May 10th.

P. C. SMITH.

SIR,—May I ask, Is it fair that doctors owning motor cars should pay only half the tax on their cars, while doctors using horse carriages should continue to pay the whole tax, as if they were used for pleasure and not as a means of earning a "mere living"?—I am, etc.,

May 10th.

AN M.D. WHO DRIVES A CARRIAGE.

SIR,—In regard to Dr. O'Connor's suggestion of making the increased Budget duties a ground for agitating for increased capitation rates for sick clubs, there are, I think, grave objections. That the average rates are too low is undeniable, but surely we have surer and firmer grounds for a higher remuneration than the occurrence of a temporary increase in the drug bill. The prices of drugs vary from time to time and Budgets are soon altered, and if we adopt Dr. O'Connor's suggestion we are forging a two-edged sword that may be used against us later on when the spirit duties are taken off or reduced and the price of drugs fall. To be logical we should then accept proportionately smaller club rates. Does Dr. O'Connor urge this? Such an arrangement can be of no benefit to the doctor, but only lead to friction and confusion.

We were mere retailers of drugs there might be some justification of this course. But I think there is no occasion for the profession to emulate the practice of the "trade," who appear to be making increased charges on spirits absurdly out of proportion to the proposed increased duty, and who (at present at any rate) are doing rather a profitable trade on the Budget.—I am, etc.,

May 9th.

CLUB DOCTOR.

PROFESSIONAL UNION AND THE BRITISH MEDICAL ASSOCIATION.

SIR,—I was interested to see Dr. Horseman's letter publicly acknowledging his debt of gratitude to the Association for what it had done in raising contract fees in his district.

As an incentive and encouragement for other Divisions to co-operate for their own internal and possibly eternal welfare, I should also like to mention what has been accomplished in my Division in that direction.

Some five years ago I was asked to organize, under the auspices of the Division, the union of practitioners in my district by calling upon and securing the signature of every medical man to a bond not to accept any new club without first consulting a committee that was appointed. In this way every man became a candidate on equal terms. The excellent results of this personal canvass are shown in the medical rates of three clubs being raised to 6s., in one case the former scale being just doubled. We have had one failure, a newcomer and non-member of the Association, who first agreed to act in concord with the other applicants for the higher rate, and then accepted the lower.

Last year a meeting was held in conjunction with a neighbouring Division, notice of which was sent to sixty-five general practitioners, and succeeded in obtaining their agreement to a minimum 6s. new club rate, and at our own last annual meeting a resolution was unanimously adopted, making it compulsory for no new club appointment to be accepted at a less rate.

I hope that other Divisions throughout the country will see their way to adopt such a scheme when clubs fall into the market, either by the decease or retirement of their medical officers. Six shillings may not perhaps be termed an ideal minimum at which to rest content, but it is in the right direction, and is certainly preferable to remaining for ever at the 3s. or 4s. rate which spells either slavery or quackery.—I am, etc.,

May 10th.

G. H. GRANT DAVIE,
Hon. Secretary, Manchester (South) Division.

HOME CONDITIONS AND EYESIGHT.

SIR,—With reference to Dr. L. F. Richardson's remarks upon the conclusions of Miss Barrington and Professor Pearson that "there is no evidence whatever that over-

crowded, poverty-stricken homes are markedly detrimental to the children's eyesight," it may be pointed out that generally when the homes are overcrowded the districts in which those homes are situated are also overcrowded, and that these conditions are distinctly detrimental to the children's vision—that is to say, to the acuity of vision.

Some time ago I examined the vision of 1,000 country-town children for the Board of Education and of 50,000 children for the London School Board, the London children being taken from every variety of district. These children for purposes of comparison have been divided into six classes or divisions, in whom the following variations in the quality of eyesight have been noted. (The figures denote percentages of defects):

- I. Jewish children residing in the East End and mostly of Russian nationality, 37.16.
- II. Children of poor working-class parents living in crowded neighbourhoods where there are no wide thoroughfares, 29.04.
- III. Same class as II, but not so much walled in and wide thoroughfares available, 27.0.
- IV. Country-town children, but mostly of poorer class than V or VI, 21.0.
- V. Children living in more or less semi-suburban localities, 19.01.
- VI. Children residing in more outlying suburbs and those attending higher-grade schools, 18.0.

With regard to the East End Jewish children, the organic defects are not greater than in the other children, but they are incapable of being corrected to the same extent as other children. Various theories have been put forward to account for this, but so far none has been found to explain the fact.

It may be mentioned that when children of Classes II and III are sent into the country at holiday times, many of them at a distance of 500 yards cannot distinguish a cow from a cottage, but their vision improves daily.—I am, etc.,

London, W., May 10th.

H. CRITCHLEY, M.D.

SIR,—Mr. Richardson quotes and seeks to explain Miss Barrington's and Professor Pearson's paradoxical statement that there is "no evidence whatever that overcrowded, poverty-stricken homes, or physically ill-conditioned or immoral parentages are markedly detrimental to the children's eyesight." The statement is not only paradoxical, but directly contrary to the experience of any one who has had much to do with an ophthalmic out-patient clinic. Apart from errors of refraction, by far the most common cause of defective vision is the presence of corneal nebulæ, resulting from phlyctenular keratitis, and this disease is undoubtedly associated with bad food, bad air, and parental neglect. How, then, does it happen that the total number of those with defective vision is not (if it is not) greater among these neglected children than among those who are better cared for? The explanation that I would suggest is that among the latter class the proportion of studious children is so much greater than among the former that they are more subject to school myopia, and that this factor, as far as the acuity of distant vision goes, is sufficient to balance the greater prevalence of corneal disease among the less cared for children.—I am, etc.,

London, W.

A. HUGH THOMPSON.

TETANUS OCCURRING AFTER SURGICAL OPERATIONS.

SIR,—I read with interest Mr. Richardson's communication¹ on post-operative tetanus, and enclose a brief note of two cases occurring in my own practice.

H. M., male, aged 10, was admitted to the General Hospital, Birmingham, April 20th, 1898, for tuberculous glands along the carotid sheath on the left side. These were excised on April 22nd, and a satisfactory convalescence followed until May 4th, on which day the boy was to be discharged from hospital. The sister of the ward then mentioned that the patient complained of a stiff neck, and on examination I found the head in a position due to spasm of the left sternomastoid. The patient swallowed with difficulty, but there was no stiffness of the jaw or pain on opening it, no definite twitchings of the muscles; the wound was healed except for a tiny place at the point of insertion of the drainage tube. The subsequent daily history showed a constant increase in the gravity of the symptoms, which became typically those of ordinary tetanus, and on May 7th breathing was very difficult, owing apparently to spasm of the

¹ BRITISH MEDICAL JOURNAL, April 17th, 1909, p. 948.

diaphragm. On May 8th the spasms were very bad, and the patient was given chloroform for a short time, and artificial respiration was performed. He died on the morning of May 10th.

Tetanus antitoxin was given six-hourly, beginning on May 5th and continued till the time of death.

The second case was in a private hospital. A lady aged 35, the subject of early carcinoma of the breast, was operated upon on Halsted's lines on October 31st, 1905. The wound healed *per primam*, and the patient was getting up, but on November 13th it was noticed that she was perspiring rather freely, and again on November 14th: on November 15th pain was complained of in the neck and jaw, and it was found that the muscles of those parts were definitely rigid. From this time onwards the symptoms of tetanus were well marked, and continued to increase until November 25th, when they began to abate slightly, but rigidity of the muscles of the back and to some extent of the abdomen continued until December 8th, when it finally disappeared. Tetanus antitoxin was administered every six hours from November 15th until November 26th, subsequently at less frequent intervals till December 1st, then once a day for three days, then every other day until December 11th, when the antitoxin was discontinued. An occasional dose of potassium bromide was also given, and from time to time morphine when severe pain was complained of and sleep seemed to be badly needed.

An interesting point in connexion with this case is that when I saw the patient's husband and told him of the grave condition which threatened his wife, he said that he had at once recognized the nature of her complication because some months previously he had lost one of his horses from lockjaw, and his wife's symptoms reminded him of those from which the animal had suffered.

Whilst all the elements entering into an operation which is followed by tetanus will naturally be closely scrutinized by the operator, I am bound to say that I had not particularly attributed blame to the catgut employed. My methods of preparing catgut have varied during the period covered by these two operations, but I have always periodically tested the gut by cultivation, and have had no reason to suspect that it was infected by any pathogenic germ at any time.—I am, etc.,

Birmingham, May 15th.

GILBERT BARLING.

SCHAUDINN'S OBSERVATIONS ON HALTERIDIUM.

SIR.—The importance of Schaudinn's work to scientific medicine is so pre-eminent that it would be extremely unfortunate were an impression to become current that on a material question of fact the accuracy of his observations had been successfully impugned. Two separate passages in the last issue of the *BRITISH MEDICAL JOURNAL* (May 8th, 1909) seem, however, to convey the idea that on a zoological point closely connected with the parasitic haematology of man the investigator was mistaken.

Most of Schaudinn's researches were so complex and technical that confirmation has necessarily been tardy; and, for the same reason, in none of them has it been so long delayed as in the case of his work on halteridium. In view of recent observations, however, these criticisms can scarcely be justified; and it now appears to be probable that Schaudinn's conclusions on the developmental changes of halteridium, as on questions of more immediate medical interest, will be fully accepted by zoologists. This agreement is clearly indicated in an article on nuclear dimorphism in halteridium by Dr. H. M. Woodcock,¹ in which, after referring to the work of Lühe and Miyajima on *protoplasma*, he says:

This feature (nuclear dimorphism) in halteridium, even regarded by itself, is, to my mind, most suggestive; and it is with very great pleasure that I bring forward what is, I believe, the first definite piece of evidence tending to confirm one, at all events, of Schaudinn's celebrated conclusions.

—I am, etc.,

London, W., May 10th.

W. CARNEGIE BROWN.

THE CAUSE OF DYSMENORRHOEA.

SIR.—In the *JOURNAL* of April 17th Dr. G. E. Herman returns to the consideration of dysmenorrhoea, and the expression of an opinion as to its causation by so eminent a gynaecologist must perforce command widespread attention.

Dr. Herman remarks that in about one-third of all cases the pain suddenly begins after years of painless menstruation. Thereupon he enunciates a theory of causation which assumes the presence of a centre in the spinal

cord or sympathetic system, having control over the movements of the genital canal. To the imperfect development of this hypothetical centre is ascribed the characteristic pain of spasmodic dysmenorrhoea.

What, then, may I ask, is the degree of development of this centre in the class of patients to which reference has just been made?

Their painless history of years' duration effectively debars any association with such a maldeveloped "sexual" centre, and yet the sequel to their period of normal menstruation, we are told, is dysmenorrhoea. In the course of his address, Dr. Herman again states his well-known objections to the "obstructive" theory of this disease. Nevertheless, in speaking of the normal dilatation of the cervix during menstruation, he adds, "In dysmenorrhoea this natural dilatation is absent, and in consequence the contractions of the uterine body are morbidly violent and painful." Save a mechanical stimulus emanating from the cervix, in what other way can the latter evoke these violent and painful movements from the musculature of the uterine body? Comparison with other viscera affords abundant proof of the fact that such movements of involuntary muscle constantly occur in the presence of some mechanical obstruction.

That "the canal in its undilated, unrelaxed state is quite big enough to let the patient bleed to death through it" may be true of an intermenstrual period, and of that alone; for I am not aware of any observations which have been made as to the patency or otherwise of the cervical canal during the acme of a dysmenorrhoeal spasm, and these alone would be apposite to the question of cervical obstruction. I submit that, during an attack, the lumen of the canal is temporarily occluded by spasm of the cervical musculature, and the consequent relative obstruction thereby produced evokes the painful spasms from the uterine body. Disappearance of the pain in a few hours follows upon dispersion of the cervical stenosis, and is accompanied by establishment of the menstrual flow.

Least the purpose of these remarks be misconstrued, let me hasten to add that I have penned them in no spirit of carping criticism, but with due appreciation of the exact statement and acute reasoning to be found in Dr. Herman's admirable and authoritative address.—I am, etc.,

Dukinfield, May 7th.

GERALD RALPHS, M.B.

COAGULATION TIME OF THE BLOOD.

SIR.—In a letter in your last issue, Professor Sabrazès states that I borrowed and altered his method of estimating the coagulation time of the blood.

Until I received a letter from him, two or three months after the publication of my paper, I did not even know that he existed, much less that he had written a paper on, or discovered a method for estimating, the coagulation time of the blood.

My method was suggested to me by independent observation during routine work on the Widal reaction for typhoid, where the samples are received for examination in small glass capillary tubes.—I am, etc.,

Edinburgh, May 8th.

J. P. McGOWAN.

SIR.—I think my deductions from Dr. Addis's figures are correct. As I understand him, he made three observations a day for fifty days = 150 observations. Of these, the shortest time was 8 min. 45 sec., and the longest 11 min. 41 sec. The longer of these times exceeds the shorter by 2 min. 56 sec., which is 33.5 per cent. of 8 min. 45 sec., and 25.1 per cent. of 11 min. 41 sec. I took the percentage on the smaller quantity because I am accustomed to do so, and find it on the whole more convenient; and on this basis it is, I think, correct to say that there is a difference of 33 per cent. among 150 trials. The variations in each case of his subsequent experiments are very much less than this, and are, in comparison, remarkably uniform.

I have found that the blood last drawn frequently, but by no means constantly, coagulates first. Dr. Addis finds that it constantly does so; and as a method which gives constant results is, *prima facie*, more accurate than one whose results are inconstant, it would seem that his method is to be preferred to mine. On the other hand, I have found in a very large number of observations that the clotting time shortly after a meal is constantly less

¹ *Quarterly Journal of Microscopical Science*, January, 1909.

than the clotting time shortly before a meal, while Dr. Addis has constantly found no difference in this respect. The difference may be due to a difference in the composition of the meals. It is clear that the clotting time is extremely sensitive to disturbance, and very minute alterations in the conditions in which the blood is placed have a very sensible influence upon the rapidity of coagulation.—I am, etc.,

London, May 7th.

CHAS. MERCIER.

TSETSE FLY AND GAE.

SIR,—The intimate association of tsetse fly with buffalo has, as your readers are no doubt aware, been much emphasized recently by Mr. Selous; and I now desire to bring to notice instances of what appear to be an unquestionably close association between tsetse fly and members of the *Suidae*, represented mainly by wart hogs and bush pigs in this country, and widely distributed here as in other parts of Africa.

Some time ago I was informed by one of our medical officers that he had seen *Glossina morsitans* settling on wart hogs he had shot; but I then thought nothing more about the matter. Lately, the resident of an adjoining district, writing on the subject of the distribution of tsetse fly in his neighbourhood, stated that he had observed these flies, which, on the captures being submitted, proved to be *Glossina morsitans*, settle on the carcass of a wart hog literally in hundreds.

I presume that these observations tend, at any rate, to indicate that where there are wild pigs, there tsetse also are present; and further, that the species, *Glossina morsitans*, apparently feeds voraciously on pig's blood.

Last week I received a report from a medical officer stationed at the north end of the lake (Nyassa) in connexion with measures directed against the entry of sleeping sickness into the Protectorate. *Glossina fusca*, a species of tsetse which, it will be remembered, has been shown experimentally to be capable of transmitting *T. gambiense*, had previously been located by two observers at the north end of the lake in a very restricted locality; and Dr. Davey, the medical officer here referred to, proceeded to this spot to ascertain whether the fly was still to be found there. His search proved fruitless, and after travelling about four miles he saw a bush pig, which he bagged. On approaching it he found that what appeared to be tsetse flies had settled on the carcass; but his boy, who carried a fly net, not being with him at the time, he killed two of the flies, and on examination found that they were *Glossina fusca*.

I submit these observations for what they may be worth, and refrain from making any deductions therefrom.—I am, etc.,

H. HEARSEY,
P.M.O., Nyassaland.

Zomba, March 12th.

AN APPEAL.

SIR,—We desire to bring under the notice of your readers the case of a registered medical practitioner of many years' standing, and in good repute in this city. Owing to circumstances of a family nature, not in the least degree discreditable to him, and to his indifferent health of late, he is in urgent want of pecuniary help to enable him to maintain his position. We therefore venture to appeal for that assistance to the members of his own profession, who are always willing to help their brother practitioners.

Any of the undersigned will be glad to receive any donations that may be kindly sent in response to this urgent appeal.—We are, etc.,

ANDREW J. HORNE,

President, Royal College of Physicians of Ireland.

JOHN LINTAIGNE,

President, Royal College of Surgeons in Ireland.

JOHN W. MOORE, M.A., M.D., D.Sc., F.R.C.P.I.,

40, Fitzwilliam Square, Dublin.

CHARLES R. CAMEON, Knt.,

51, Pembroke Road, Dublin.

May 11th.

SEWER AIR.

SIR,—I am glad to note in your annotation on sewer air¹ you mention the work of Dr. David Arthur, which has been somewhat overlooked. My own bacteriological ex-

periments² and topographical investigations corroborated Dr. Arthur's theses as to certain sewers or drains which Professor Delépine expressly excludes from the general application of the results of his valuable and laborious investigations.—I am, etc.,

Norwich, May 8th.

J. T. C. NASH.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The Admission of Women.

THE following memorial has, we are informed, been submitted to the Home Secretary in reference to the proposed new by-law concerning the admission of women:

[COPY.]

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Right Honourable Herbert Gladstone, M.P., etc.,
Home Secretary.

SIR,

On behalf of this Society we desire to enter an emphatic protest against the mode of admitting women to the Diplomas of this College contemplated by the Council of the College in the By-law (Section XXVI) now submitted for your approval and sanction.

1. We wish to point out that the proposed procedure under the Medical Act of 1876 (39 and 40 Vict., c. 41) is totally gratuitous and unnecessary, since it is equally open to the College Council to admit women in the same manner as all previous changes in the constitution of the College have been made, namely, by means of an amending Charter.

2. The effect of admitting women under this Act of 1876 must be to create an inferior order of Fellows and Members who are unable to take any part in the government, management, and proceedings of the College. Although the whole property of the College is vested in the existing Members and they provide a very large proportion of the College income, it is unfortunately at present the case that they have no voice in the government or management of the College. Therefore the women Members under the Act of 1876 would not be in much worse case than their male colleagues are at present; but they will be debarred for all time by the Act from ultimately acquiring the same position as the men. The case of the women Fellows under the Act would be, however, different. In the Fellows of the College is at present vested the whole right of electing and sitting upon the Council; they therefore control the entire "government, management, and proceedings." The women Fellows, if this by-law is sanctioned, will be for ever prevented from sharing in this right.

3. We further submit that the adoption of this Act by the Council is a retrograde step in view of the position which women have attained in the profession since 1876. We believe that women are now admitted for degrees or diplomas by all the qualifying bodies except the older Universities (Oxford and Cambridge), but so far as we can learn none of these bodies have utilized the provisions of this Act nor made any distinction between their male and female graduates or diplomates. On the contrary in all the newer Universities provision has been made in the Charters for equalizing the position of the sexes.

4. It will be within your knowledge that a Royal Commission has been appointed to consider the whole question of University Education in London. The Royal Colleges of Physicians and Surgeons have appointed delegates to confer with delegates from the University of London, with the object of establishing a scheme for conjoint examinations between these three bodies, in order that a University degree may be obtainable by the average London student on the same conditions as at the provincial Universities. A joint representation is to be made on behalf of this scheme to the above-mentioned Royal Commission. The position of women graduates under this scheme if this By-law is sanctioned will be anomalous and unprecedented. It is well known that at London University there are no disabilities on the ground of sex. Therefore as regards one of the bodies co-operating in this scheme and granting a conjoint degree women will be admitted on the same footing as men, but as regards the others they will be placed in an altogether inferior position.

5. At the last Annual General Meeting of Fellows and Members the following resolution was carried *unanimously*: "That this meeting is of opinion that women when admitted to the Diplomas of the College should have equal rights with men." In par. I, Section XXVI, it is stated that women will be admitted "on the same terms and conditions as men," but in par. 2 totally different conditions are imposed under the Act of 1876.

6. Last year the Council took a poll of the Fellows and Members on the question whether women should be admitted at all. The result of this poll showed a majority against the proposal. The Council has therefore refused to abide by the result of its own poll. A supplementary poll was at the same time taken by this Society, asking three questions, which the Council

¹ BRITISH MEDICAL JOURNAL, May 8th, 1909, p. 1142.

² "Sewer air and its purification, especially from a bacteriological point of view," *Public Health*, 1902.

refused to include in their poll. One of these questions was: "If you desire that women should be admitted, do you consider that they should be admitted under Charter, with full Collegiate rights?" To this over 90 per cent. of the members replying did so in the affirmative. We therefore ask you not to sanction this By-law on the grounds:

1. That it is unnecessary;
2. That it places women in an inferior position under an Act not adopted by any other qualifying body.
3. That par. 1 is in that contradiction to par. 2.
4. That women will be invidiously treated under the scheme for a future London degree; and
5. That the Council have throughout this matter acted directly in the face of the opinion expressed by the Fellows and Members of the College. Should you require any further information, we very respectfully ask you to receive a small deputation from this Society.

Signed on behalf of the Committee of the Society,

W. G. DICKINSON,

A. S. MORTON,

Hon. Secs.

May 1st, 1909.

PROPOSED BY-LAW.

SECTION XXVI. Admission of Women.—(1) Pursuant to the powers conferred by the Medical Act, 1876, and subject to the provisions therein and hereinafter contained, women may be admitted as Members and Fellows of the College and may obtain Diplomas in Dental Surgery on the same terms and conditions as men; and so far as it is necessary to give effect to this By-law, words in the By-laws and Regulations of the College which import the masculine gender shall also import the feminine gender, and all proper alterations shall be made in the form of the Letters Testimonial, Diplomas, Certificates, and Licences granted by the College. (2) Women shall not be eligible as members of the Council and shall not vote at or take any part in any election of a member or members of the Council, or attend any meeting of Fellows or of Fellows and Members (except meetings convened for the delivery of Lectures or Orations), or otherwise take any part in the government, management, or proceedings of the College. (3) Women shall not be eligible as members of the Court of Examiners or for any Examinership to which the Council appoint.

UNIVERSITY OF LONDON.

KING'S COLLEGE.

Advanced Lectures on Physiology.

THE following two courses of special lectures will be delivered in the Physiological Laboratory, King's College, London, during the present term:

1. A course of eight lectures on the Senses of Hearing, Taste, and Smell, by Professor C. S. Myers, M.A., M.D., on Fridays (May 7th to June 25th), at 4.30 p.m.
2. A course of four lectures, with experimental demonstrations, on the Secretion of Urine, by Professor T. G. Brodie, M.D., F.R.S., on Mondays (June 7th to 28th), at 4.30.

These courses are free to all internal students of the University of London, and to all medical practitioners on presentation of their cards.

UNIVERSITY OF LIVERPOOL.

INSTALLATION OF THE NEW CHANCELLOR: HONORARY DEGREES.

ON Saturday, May 8th, the Earl of Derby was installed as Chancellor of the University of Liverpool, and a number of honorary degrees were conferred upon distinguished persons. St. George's Hall, in which the ceremony was held, was crowded. The handsome, massive mace presented to the university by Dr. Richard Caton, was used for the first time on this occasion.

The Earl of Derby, who succeeds his father in the office of Chancellor, was introduced by the Vice-Chancellor, who conferred upon him the degree of Doctor of Laws.

The new Chancellor expressed his sincere anxiety to follow the traditions of his house by taking part in the public life of the county.

Honorary degrees were then conferred as follows:

Doctor of Laws:

- The Right Honourable Arthur James Balfour.
- Admiral Lord Charles Beresford.
- The Right Honourable Augustine Birrell.
- The Right Honourable Sir John Tomlinson Brunner.
- Richard Caton.
- The Right Honourable the Earl of Crewe.
- Robert Gladstone.
- Sir Donald MacAlister.
- Guglielmo Marconi.
- Field Marshal the Right Honourable Earl Roberts.
- Paul Vinogradoff.

Doctor of Letters:

- Edward Meyer.

Doctor of Science:

- Francis Darwin.
- John Lancelot Todd.

Doctor of Engineering:

- The Honourable Charles Algernon Parsons.

Master of Arts:

- William Fergusson Irvine.

Professor MacCunn, in presenting Dr. Caton, introduced him as one to whom the university owed a far deeper debt than it could ever hope to repay. Eminent and honoured in his pro-

fession, his name would be enduringly associated with the rise and progress of the Medical School of Liverpool, with the arduous labours of the Chair of Physiology, with the philanthropic work of the Royal Infirmary, and with the enterprise of the Liverpool School of Tropical Medicine. To none more than to him did the university owe its translation from dream to conception, and from conception to accomplished fact. He had also carried the instincts and methods of the man of science into the School of Archaeology, and the public spirit of the citizen into the humane and imperious problems of public health and the housing of the poor. Nor, with the memorable tenure of the Lord Mayoralty of the city fresh in their minds, were they likely to forget that in honouring him they were rendering what was due to a citizen in whom lifelong academic ties, sympathies, and services had been united with all that was unselfish, strenuous, and honourable in the traditions of our municipal life. The students who greeted the honorary graduates with songs composed for the occasion and accompanied by the great organ, received Dr. Caton with the following lines:

He's a dear kind doctor,

As kind as ever could be;

He's a dear kind doctor,

For city and 'Varsite.

If you went to Caton,

And tinkled the town hall bell,

The moment he'd take your pulse,

You'd always feel quite well.

In presenting Sir Donald MacAlister, Professor MacCunn said that he was eagerly claimed by Liverpool as one of their most distinguished sons, since it was the privilege of one of her great schools to witness and to hasten the dawn of those commanding and versatile intellectual powers which had won such signal and widespread recognition throughout the length and breadth of the academic and scientific worlds. The University of Liverpool was particularly delighted to honour the distinguished Principal and Vice-Chancellor of the University of Glasgow, which was thrice fortunate in having called to its service the varied knowledge and experience which Sir Donald MacAlister possessed.

In presenting Mr. Francis Darwin, Professor Harvey Gibson described him as one of the foremost authorities in botany, a pioneer in experimental physiology, and the author of a model biography of his great father.

Professor Ronald Ross, in presenting Dr. J. L. Todd for the honorary degree of Doctor of Science, spoke of his distinguished and arduous labours in connexion with sleeping sickness. In 1902 Dr. Todd was recommended to the School of Tropical Medicine by Professor Osler and Professor Adams, and became assistant lecturer on tropical medicine, and afterwards director of the laboratories at Rancorn. Practically at his own expense he furnished the experimental research laboratory of the school. He especially distinguished himself by devoted research in Africa and in Liverpool with regard to sleeping sickness and spirillum fever. The gospel of the prevention of sleeping sickness by organized methods, which he constantly preached, had been accepted by the British Colonial authorities and by the Belgian officials on the Congo. He was engaged with the late Dr. James Everett Dutton, who fell a martyr to work on the Congo expedition of 1903-4-5 on sleeping sickness. On that occasion, working independently, they made discoveries which proved the discovery in British East Africa in connexion with the so-called tick fever made by Dr. Ross and Dr. Milne some time before. Largely owing to the work of Dr. Todd, and that of his collaborators, the Liverpool School had received an increased grant from the British Government. It was with great reluctance that the Liverpool School recently parted with Dr. Todd, but he felt that after six years' absence from his native land of Canada he must accept the post of associate professor in protozoology in McGill University—his own university—that had been offered to him.

EXTRAMURAL SCHOOL OF MEDICINE, EDINBURGH.
DR. JOHN KEAY, Medical Superintendent, Bangour Village Asylum, has been appointed jointly with Sir John Batty Tuke, Lecturer on Mental Diseases at the Extramural School of Medicine, Edinburgh.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examination indicated:

THIRD PROFESSIONAL.—C. E. Drennan, M. Drummond, R. A. W. Ford, G. J. Fraser, J. Gornley, P. Grace, F. J. Graham, L. A. Moran, F. H. Montgomery, J. McMullin, T. B. Newman, R. O'Connor, M. A. O'Callaghan, W. Rabby, A. A. Russo, H. C. Smyth, T. M. Thomson, F. W. Warren, R. H. Weir.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

CARDS TO PATIENTS.

W. F. C. W.—There is no objection to information as to a branch surgery being given to patients, but there is always a danger that cards may be handed about and will then be regarded as advertisements.

Medico-Legal.

CHARY JOHN wishes to know the best test for a case of feigned deafness and blindness on one side following a railway accident.

A DEATH FROM CHLORODYNE.

At an inquest held recently by the Coroner for the City of London, the jury brought in a verdict of accidental death from an overdose of chlorodyne. The case had been adjourned in order that an analysis of the viscera and of the stomach contents might be made, since one medical witness held that death was due to heart failure accelerated by alcoholism; while the divisional surgeon of police, Dr. Kearney, detecting the odour of chlorodyne, believed that death was due to this drug, as proved to be the case. The analysis was carried out by Dr. Womack of St. Bartholomew's Hospital, who said that the deceased appeared to have taken about 4 oz. of chlorodyne. Such an amount would contain 1 gr. of morphine, in addition to Indian hemp, treacle, extract of liquorice, and prussic acid. In response to the coroner's inquiries, it was pointed out that purchasers of chlorodyne were not obliged to sign the Poisons Register, because it did not contain quite 0.4 per cent. of prussic acid, or as much as 1 per cent. of morphine. The Coroner said he thought that the law ought to be altered, vendors of secret cures and proprietary remedies being obliged to state the contents on the bottles and wrappers used.

WORKMAN'S COMPENSATION CASES.

Serious and Permanent Injury.

A case (Shenton v. Stafford Coal and Iron Co.), decided by Judge Ruggs at Stoke on April 15th, is important as showing that it may sometimes devolve on a medical referee to decide whether an injury is "serious and permanent." In his judgement, the judge said that the applicant was a miner, and the defence set up was that he had been guilty of serious and wilful misconduct, and that that was the cause of the injury. After hearing the case, he came to the conclusion that the applicant had been guilty of serious and wilful misconduct, and that he came under the section of the Act which said that no workman who brought about his injury by his own serious and wilful misconduct could recover compensation, except in two cases. One exception was that where death resulted, and where compensation was claimed by the dependents, and the other exception was where the injury resulted in serious and permanent disablement to the workman himself. In the course of the case, he expressed the opinion that he was obliged to find on the facts that the workman was guilty of serious and wilful misconduct. Then the question arose, Was the injury of a serious and permanent character? There was a great conflict of medical opinion, and in the end it was decided that the applicant should be seen and examined carefully by an entirely independent medical man, who was one of the medical referees of the court. This had been done, and the medical referee reported to him that there was no doubt, in his opinion, that the injury was of a serious and permanent character. Consequently, the man was entitled to compensation. Workmen, particularly those engaged in mines, should know the great risk they ran of being deprived of their compensation altogether if they deliberately broke the rules of the mine, or if—as was in his opinion equally bad—knowing it was their duty to make themselves acquainted with the rules, they deliberately abstained, as in this case, from making themselves acquainted with them. It was only under very rare circumstances, when these facts existed, that workmen could recover compensation. Fortunately, in one sense, and unfortunately in another—because the plaintiff's injury had been declared to be both serious and permanent—the Act of Parliament, very liberally in the interests of the workman, declared that even where he had brought the injury upon himself by his own misconduct he should still be entitled to receive compensation. The judge said that he did not understand the Act of Parliament to mean that it was necessary for the injury to be lifelong. It must be an injury the effects of which would not be temporary, and it was an injury which might perchance last the man's life.

A Claim in Respect of Ringworm.

In the case of Millington v. Woodward, which was heard at the St. Helens County Court on April 22nd, the applicant had been employed as a blacksmith's improver. He was first employed in August, 1908. At the end of October he was sent to attend a horse which was suffering from ringworm, and in consequence he caught the disease. Judge Sand, after hearing the evidence of the applicant, said he could not see how it could be contended that Millington did not contract the disease from the horse. Dr. Officer said that the lad had suffered from most virulent ringworm. Dr. Jackson, who had examined the applicant for the insurance company, said that on January 25th the lad was perfectly recovered, but there was no doubt that he had had ringworm. The Judge gave an award in favour of Millington for 8s. a week from November 17th up to date.

Loss of a Hand.

In a case which was heard at the Bradford County Court on May 4th the applicant had been at work in the respondent's quarry. When loading a wagon a small piece of shale or stone

flew out and caused a cut on the thumb. Blood-poisoning in the right hand and arm followed, necessitating the amputation of the hand. The employers resisted the claim on the ground that there was nothing to connect the injury with the accident. Judge Graham, in giving judgement, said that he had thought during the argument that the poison might have been introduced into the system by reason of the applicant bandaging the thumb with a dirty rag. Dr. Horrocks, however, a medical man of great experience, had expressed the opinion that the poison entered the system through the wound. His Honour therefore held that the applicant had made out a *prima facie* case. The applicant would have 8s. 8d. a week.

PAYMENT TO MEDICAL WITNESSES IN THE CORONER'S COURT.

R. M. G., a member, makes inquiries into this matter, and many a time and oft we have replied to similar questions, especially those which related to the fees payable to medical officers of hospitals and workhouses, in which our correspondent is especially interested.

"* We would refer our correspondent to the BRITISH MEDICAL JOURNAL of September 14th, 1907, in which we published a full report on the subject, quoting various opinions and interpretations that had been expressed by various local authorities, and the results. The whole question turns upon the reading of Subsection 2 of Section 22 of the Coroners Act, 1887, with which all coroners are familiar. This section is somewhat ambiguous. We believe the coroners themselves are quite ready and willing to pay the medical fees if they were assured they would be reimbursed by the local authorities. It is quite open to "R. M. G." to sue the coroner in the county court, but we should advise him first to consult a solicitor. At the present time a Departmental Committee of the Home Office on Coroners Law is sitting, and a subcommittee of the Medico-Political Committee of the British Medical Association is preparing evidence for submission to it. A bill to amend the Coroners Act prepared for the Association some years ago contained a clause providing that every legally qualified medical practitioner who attended a coroner's inquest in obedience to a summons from the coroner should be entitled to receive remuneration at the rate of 1 guinea for every day such practitioner attended to give evidence.

AND

POOR LAW MEDICAL SERVICES.

PUBLIC VACCINATORS AND POOR LAW DISTRICT MEDICAL OFFICERS.

On January 18th, 1909, the following letter was addressed to the President of the Local Government Board on behalf of the Association of Public Vaccinators of England and Wales:

1, Mitre Court Buildings,
Temple, E.C.

Sir,—

The Council of this Association has had before it on many occasions during the past 12 months complaints from Public Vaccinators, who are also District Medical Officers, that they are compelled to do the work of District Medical Officers for inadequate remuneration, the plea of the guardians being that such inadequate remuneration is amply made up by the fees received from Vaccination.

So far has this been carried that in several instances where a Public Vaccinator has resigned his District Medical Officership he has been immediately deprived of his Vaccination Appointment.

This appears to the Members of the Council most inequitable and they would like to lay their views upon the subject before you personally and with that object I am requested to write and ask you to favour them with an appointment when a small deputation could wait upon you for that purpose.

The Deputation would also like to be permitted to mention the question of fixity of tenure, as, in the opinion of the Council, that question is closely connected with the matter above referred to.

The Council will be meeting again on the 29th inst., and I should esteem it a favour if you could let me have a reply to this letter before that date.

I am, Sir,

Your obedient Servant,
(Signed) CHAS. GREENWOOD,
Organizing Secretary.

This letter was acknowledged on January 19th, and on January 28th the President of the Local Government Board asked to be furnished with a short statement in writing of the points upon which the Association of Public Vaccinators desired an interview. To this communication the following reply was sent:

March 31st, 1909.

To the Secretary of the
Local Government Board.

Sir,—

Referring to the Association's letter of January 18th last, and to your answer thereto of the 28th ultimo, and in compliance with the President's request, we now beg to submit the following short statement of the points upon which the Association are seeking an interview:

1. The complaints of public vaccinators who are also district medical officers are as follows:

- (a) That their work as district medical officers is inadequately paid for, because the guardians contend that a part of the remuneration they receive as public vaccinators must be regarded as payment for their work as district medical officers, and reduce their remuneration accordingly.

If this contention is correct, their contracts as public vaccinators are incorrect and misleading, as they are performing their duties as public vaccinators for remuneration below the statutory minimum, and consequently are at a disadvantage as compared with other public vaccinators who are not also district medical officers.

For Example.—(1) The Aston Board of Guardians recently proposed dividing their union into two districts and appointing a whole-time officer in each, but to pay them, in respect of their district medical officers' duties, on a different basis. In one district, with a population of 91,000, the salary as district medical officer was to be £200, whilst in the other, with a population of 114,000, it was to be only £100, and this despite the fact that when this latter district was originally formed your board insisted upon a minimum of £150.

The reason given by the guardians for this difference in salary was that the vaccination was more valuable in the latter district than in the former.

The Newhaven Board of Guardians, when applied to by one of the public vaccinators for increased vaccination fees, refused to grant same, because this public vaccinator, as district medical officer, was considered to be fairly well remunerated.

These two examples of the way in which the remuneration of district medical officers is set off against their remuneration as public vaccinators and vice versa are only samples of what is going on in many unions.

- (b) That in cases where public vaccinators who are also district medical officers resign the latter appointments because of the inadequacy of their remuneration therefor, their contracts as public vaccinators are terminated by notice.

Examples.—1. The Pontefract Board of Guardians peremptorily dismissed the public vaccinators for the Castleford District because they resigned their positions as district medical officers owing to the inadequacy of the salary, which worked out at seven farthings per attendance (which included medicines). The board accepted the resignations, although they admitted that the work was well done, and despite the fact that when the question of the vaccination fees was being discussed the board decided the two appointments were entirely separate, and the vaccination fees were reduced, and agreed upon, the vaccination contracts were forthwith terminated solely because the public vaccinators had felt compelled to resign the district medical officeships.

2. The Poole Board of Guardians in the same manner and for the same reason (namely, resignation of the district medical officership) put an end to the vaccination contract with Dr. M. Eden Paul.

3. Similarly, the Driffield Board of Guardians peremptorily dismissed Dr. A. T. Brand from his post as public vaccinator.

2. As to the question of fixity of tenure:

(a) The Departmental Committee of 1904 appointed to inquire into the subject of vaccination expenses—after pointing out (par. 57) that the position of public vaccinators was a serious one in view of the fact that, although they may have given up the greater part or even the whole of their private practices in order to devote their time to public vaccination, they are merely contractors and liable to have their contracts determined at twenty-eight days' notice—suggested (par. 95) that the law should be amended so that every public vaccinator might become an "officer," "and . . . have fixity of tenure," and "that public vaccinators generally . . . would regard such a change as some compensation for the reduction which we propose should be made in their fees."

(b) The Committee further suggested (par. 96) that when a public vaccinator was under contract for vaccination at the time when any new Act or Order affecting fees came into force he should have the option of remaining a contractor instead of becoming an "officer," in which case no reduction below the minimum fee payable under the Order of 1898 should be made.

Despite the reduction in fees by the board's order of 1907, the suggestions of the Departmental Committee that fixity of tenure should be given as some compensation for such reduction has not hitherto been acted upon.

We are, moreover, requested to inform you that there still exists a strong feeling of disappointment and dissatisfaction in regard to the amount fixed as a minimum fee for domiciliary vaccination, which fee, in view of the obligations entailed and the responsibilities incurred, is

considered under any circumstance at present existing wholly inadequate.

Upon these points, therefore, the Council of the Association are anxious to meet the President and discuss with him more in detail the position of public vaccinators.

We are, sir,

Your obedient servants,
(Signed) ARTHUR DRURY, M.B., C.M.,
President.
CHAS. GREENWOOD,
Organizing Secretary.

To this the following reply was received:

Local Government Board,
Whitehall, S.W.,
May 3rd, 1909.

Sir,—

I am directed by the Local Government Board to advert to your letter of the 31st March last, containing a statement of the points upon which the Association of Public Vaccinators of England and Wales desire an interview with the President.

The points referred to in that statement have been brought to the President's notice, and have received his consideration, and under the circumstances it does not appear to him necessary to trouble the proposed deputation to attend.

With regard to the combination of the offices of district medical officer and public vaccinator, the board recognize that in ordinary circumstances where these offices are held together the remuneration for each office should be proportioned to the duties of the office. But they think that where an officer is required to devote his whole time to public appointments the guardians may properly have regard to the total remuneration which will accrue to him in respect of those appointments. The board have no power under the existing law to prevent the guardians from giving notice to a public vaccinator to determine his contract where he has resigned office as district medical officer, nor are they empowered to give public vaccinators fixity of tenure.

I am, Sir,

Your obedient servant,
(Signed) JOHN LITHBY,
Assistant Secretary.

THE DIPLOMA IN PUBLIC HEALTH.

At a meeting of the Metropolitan Asylums Board on May 8th the Hospitals Committee reported having considered a letter from Dr. H. Kenwood, Professor of Hygiene at University College, London, in which he asked, on behalf of members of his course for the diploma in public health, whether the existing conditions under which the candidates are "signed up for the three months' attendance upon a fever hospital which is required by the regulations for the diploma" can be modified. The medical officer for the general purposes (Dr. Cuff) submitted a full report on the subject, giving in detail the steps which led to the adoption of the present regulations, and pointing out that the present scheme does not accommodate itself to the circumstances of the large majority of the candidates for the diploma in public health. The existing arrangements require candidates who wish to study administration in the board's hospitals to reside therein. The committee had gone into the matter very carefully, and while of opinion that the present arrangements involving residence should be retained unaltered, thought the steps should be taken as suggested by Dr. Cuff to supplement the facilities now afforded by instituting at two of the board's hospitals, as an experiment, classes at which candidates for the diploma might receive instruction in administration without being compelled to enter into residence. They recommended:

That, subject to the sanction of the Local Government Board, the existing facilities for the study of hospital administration afforded to candidates for the diploma in public health is supplemented by the institution at two of the hospitals, as an experiment, of classes for the instruction of candidates in hospital administration without requiring them to enter into residence, and that the Local Government Board be furnished with a copy of the report on the subject by the medical officer for the general purposes (Dr. Cuff). This was agreed to without comment.

CHARGES AT ISOLATION HOSPITALS.

J. L. M.—It is becoming more and more the custom for sanitary authorities to make no charge for patients admitted into isolation hospitals. There is nothing to prevent a charge being made.

EDUCATION AUTHORITIES AND MEDICAL TREATMENT.

F. T. T.—The Education (Administrative Provisions) Act, 1907, Clause 13 (1) (b), gives a local education authority "power to make such arrangements as may be sanctioned by the Board of Education for attending to the health and physical condition of the children educated in public elementary schools." Unless the local education authority has obtained the sanction

of the Board of Education to some special regulation giving the power to enforce treatment, which is exceedingly unlikely, and which would be open to challenge, it would not have a legal right to have a child's hair clipped on one side. It can, however, indirectly insist on treatment being provided by excluding the child and prosecuting the parents for its non-attendance should they fail to have the child properly treated.

Obituary.

CHARLES MACKENZIE MACRAE, M.D.,

STORNOWAY.

A VERY old, if not the oldest, member of the medical profession in the north of Scotland, Dr. C. M. Macrae, of Barvas Lodge, Stornoway, died, at the ripe age of 91, on May 4th. He retired from practice three years ago on account of growing infirmity, and resigned his public appointments at the same time: one of them—that of medical officer of health for Stornoway—he had held for over sixty years.

Dr. Macrae was an M.D. of Edinburgh University, taking that degree as well as the L.R.C.S.Ed. in 1848. He laboured all his professional life amongst the Lewis islands, by whom he was highly respected. For a long period of years he and his colleague (the late Dr. Roderick Millar) had the entire charge of 30,000 inhabitants of the Lewis, scattered over an area of 650 square miles.

Dr. Macrae took a deep interest in everything that concerned the welfare of the Lewis people. He was an Honorary Sheriff-substitute, a J.P., and for many years Chairman of the Stornoway School Board. In 1895, on completion of fifty years' practice in the island, he was presented with an illuminated address and purse containing two hundred sovereigns, along with a silver tray and a tea and coffee service for Mrs. Macrae. He was the author of an article on Lewis in the *Encyclopædia Britannica*, and had written also on the medical topography of the Outer Hebrides.

HERBERT MURRAY RAMSAY, F.R.C.S.EDIN.

It is with great regret that we record the death of Mr. H. M. Ramsay, which occurred on April 29th, at the Cotswold Sanatorium, near Painswick, at the early age of 45. The immediate cause of death was tuberculosis following on an attack of infective pharyngitis contracted in the early autumn of last year.

Mr. Ramsay was the son of the late Captain Douglas Ramsay, R.N., of Aldburgh, Suffolk. He received his medical education at St. Bartholomew's Hospital, and, after taking the diploma of M.R.C.S.Eng. and L.R.C.P.EDIN. in 1885, joined the Army Medical Service, serving with the 1st Battalion Scots Guards from 1888 till 1896, when he retired, and started private practice in Hertford Street, Mayfair. He practised there with great success until incapacitated by the onset of the illness which proved fatal. He was for several years Medical Officer of the Inns of Court Rifle Volunteers, retiring in 1906 with the rank of Surgeon-Major.

Mr. Ramsay was much interested in the welfare of the soldier, and was a prominent member of the Union Jack Club; he was one of the three founders of the Canteen and Mess Co-operative Society, which has for its object the supplying of all soldiers' requirements at the lowest possible price and of the best quality. On the formation of the Territorial Force he was gazetted Lieutenant-Colonel, and put in command of No. 1 General Hospital, but his illness prevented his taking up active duty. The funeral took place at Charlton, near Malmesbury, where he and Mrs. Ramsay were well known, as they were frequent visitors at Charlton Park, and had endeared themselves to the residents of the village and district. The church was completely filled, and among the congregation were many London friends, including several members of the medical profession as well as many villagers who desired to show a last token of respect. The coffin was covered with numerous floral tributes.

We have to announce the death, on May 2nd, of Dr. DONALD MURRAY, for many years a well-known practitioner

in Leith. A native of Stornoway, where he was born sixty years ago, Dr. Murray entered Edinburgh University as an arts student, but subsequently studied medicine and graduated M.B. and C.M. at St. Andrews University. After graduation he settled in Leith, where he very soon built himself a large practice. He was Admiralty Surgeon, and had also medical charge of the troops at Leith Fort.

WE regret to have to announce the death of Dr. D. S. MACDONALD, who for the past nine years had been practising in the island of Jura. His death was indirectly due to an attack of influenza contracted some months ago. A graduate of Aberdeen University, Dr. MacDonald, after making a voyage to Labrador, commenced practice in Inverness, where he remained a few years; from there he went to Sleat, acting as Parochial Medical Officer with much acceptance. Finally, he settled in Jura, where by his devotion to duty he gained the esteem and regard of the inhabitants of that lonely island. Practitioners on the mainland have little idea of the privations of their brethren who, under very trying circumstances, have to carry on their work, in many cases far from any of their brethren, for whose advice and help they would be only too grateful. Dr. MacDonald's practice was in one of these isolated islands, and he will be much missed by the inhabitants, in whose welfare he at all times took a kindly interest. Dr. MacDonald was a widower, leaving three sons who are resident in Canada and two daughters to mourn his loss.

A considerable circle of younger Edinburgh men will hear with sorrow of the removal by death of Dr. DAVID IONE ROBERTS, a gifted and attractive personality. Born in Wales thirty-one years ago, young Roberts studied medicine in Edinburgh with conspicuous success. He was a favourite both with teachers and fellow students. He possessed qualities which made him one of the most companionable of men; he was an accomplished musician, and had a cultured voice of large range; he was an artist to his finger-tips. Soon after graduation evidences of chest weakness showed themselves. Dr. Roberts made a noble stand against the enemy and, devoting himself to work in the field of tuberculosis, took office as medical superintendent in two sanatoriums successively. Only last year, although his strength was not what his friends would have desired, he succeeded in taking the D.P.H., with a view to promotion in public health work. A valuable post was almost within his grasp, when considerations of health prevented his pressing the advantage. Unfortunately, a serious aggravation of his illness occurred this spring, and after a last brave struggle he had to give in. He passed away in Edinburgh on May 4th. He leaves, with many fond memories which will linger long, a record of a beautiful and blameless life.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are Professor Hang, Director of the Aural Clinic of the University of Munich, aged 49; Professor Ercole Galvagni, Director of the Medical Clinic at Modena, and author of various writings on clinical subjects, aged 73; Dr. Moissenet, formerly physician to the Paris hospitals; Dr. Richard Fleischer, formerly Professor of the History of Medicine in the University of Erlangen, aged 61; Dr. P. de Almeida Magalhaes, Professor of Medical Pathology at Rio de Janeiro; Dr. Laqueur, Emeritus Professor of Ophthalmology in the University of Strassburg, aged 69; and Dr. Frank W. Draper, Professor of Legal Medicine in the Harvard Medical School, Physician to the Boston City Hospital, and author of many papers on medico-legal subjects, aged 66.

UNDER the will of the late Mr. John Smith, a merchant, of Dundee, the Royal Infirmary in that city receives a bequest of £2,000, while the Royal Victoria Hospital for Incurables in Dundee benefits to the extent of £1,000, and the Gerard Cottage Hospital at Monifieth, where the deceased resided, receives £500.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.

The offices of the British Medical Association and of the British Medical Journal are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Asticology, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National).—

2531, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2531, Gerrard, BRITISH MEDICAL ASSOCIATION.

2534, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

OMEGA asks for a remedy to remove brown spots on the skin produced by bromides.

GADUS asks for information regarding the use of formalin or any other preservative in keeping fish fresh for market.

BAFFLED asks for suggestions as to the treatment of pruritus pudendi, not due to sugar, nor to uterine trouble. Solution of silver nitrate, of tar, and of lead have been tried; also calomel ointment, carbolic lotion, borax and soda lotion, and cocaine ointment. All have given temporary relief, but none has been of any permanent benefit. Is radium useful; and, if so, how is it applied?

CONTRACTS NOT TO PRACTISE: HOUSE-SURGEONS.

DR. J. F. HODGSON (Honorary Secretary, Halifax Division, British Medical Association, Trafalgar House, Halifax) writes: Some provincial hospitals require their house-surgeons to sign an agreement restricting them from practising within a certain distance from the hospital and for a certain term of years from the date of appointment. Can any of your readers supply me with the names of such hospitals, together with the limits of space and of time insisted upon?

ANSWERS.

R.M.G.—The patient was apparently suffering from poisoning by carbon monoxide, which is given off when coke is burned in a cast-iron stove if the latter becomes red hot.

J. J. H.—The Secretary of the National League for Physical Educational Improvement, 11, Southampton Row, W.C., informs us that a list of the institutions where training courses are held for the examinations of the Sanitary Inspectors' Examining Board can be obtained from the Secretary of the Examining Board, Adelaide Buildings, London Bridge, S.E. Particulars as to the examination of the Royal Sanitary Institute and the opportunities of training for it may be obtained from the Secretary of the Institute, Parkes Museum, Margaret Street, W. Particulars as to examinations, certificates, etc., are given in *How to become a Lady Sanitary Inspector*, by a Lady Inspector (30 pp., London Scientific Press, 28 and 29, Southampton Street, Strand, W.C. 1908. 6d. net); and also *Women as Inspectors* (20 pp., Central Bureau for the Employment of Women, 9, Southampton Street, High Holborn, W.C. 1907. 3d.).

ACETYLENE IN PRIVATE HOUSES.

T. J. D.—We are not aware of any harmful effects upon persons living in houses lit by acetylene. Unlike carbon monoxide, acetylene does not enter into chemical combination with the haemoglobin of the blood. There is therefore no danger so long as there is a fair amount of ordinary atmospheric air. Acetylene has to be present in fairly large percentages to do harm, and even then, in animals which have been rendered unconscious by breathing acetylene, placing the animal for a few minutes in the open air is usually sufficient to bring about recovery. Acetylene is an explosive gas when present in atmospheric air to the extent of 5 per cent.

BORAX AND BOILED MILK.

FLEET SURGEON.—The best simple test for boric acid in milk is as follows:

Make about an ounce of the milk strongly alkaline with lime water, evaporate to dryness, and ignite the residue; add

half an ounce of water to the ash and sufficient hydrochloric acid to give an acid reaction, and then a further 15 minutes of the strong acid; dip a piece of turmeric paper in the liquid and allow it to dry. If boric acid or borax was present in the milk, the paper will have a characteristic red colour when dry. Ammonia changes the colour to a dark blue-green, the red being restored on again acidifying with hydrochloric acid. The same test may be employed for butter by mixing about a quarter of an ounce with lime water, evaporating and igniting.

Boiled milk may be detected by the following test:

Add to half an ounce of the milk two drops of solution of hydrogen peroxide, shake, and then add two drops of a 3 per cent. aqueous solution of paraphenylenediamine hydrochloride. With raw milk a blue colour appears at once, or in a few minutes; with boiled milk no blue colour appears even on long standing.

LADY DISPENSERS.

W. S. P.—(1) There are two ways of becoming a qualified dispenser: (a) To take the Assistant's Certificate of the Society of Apothecaries; (b) to take the Minor Certificate of the Pharmaceutical Society. Candidates for the former pass two examinations, the one a practical test of their ability to compound and dispense medicines; and the other an oral examination in materia medica, chemistry, pharmacy, and the translation of prescriptions. They must produce a certificate signed either by a registered medical practitioner or a fully-qualified chemist, or by an assistant of the Apothecaries Society holding a public appointment, that they have received instruction in practical pharmacy for six months. Examinations are held towards the end of the first month of each quarter throughout the year. The fee is five guineas. A syllabus can be obtained on application to the Clerk of the Apothecaries Society, Blackfriars, E.C. Candidates for the Minor Certificate of the Pharmaceutical Society have to pass a preliminary examination in general education, to be approached for three years, and attend regular courses of instruction in botany, materia medica, chemistry, and other subjects, and finally to pass an examination therein. Including examination fees, tuition fees, and the cost of living, the expense of this qualification must be put down as not less than £100.

(2) Holders of Certificate (a) are eligible for appointment at any of the institutions maintained by Poor Law authorities, including the Metropolitan Asylums Board, and are frequently employed at hospitals and dispensaries, and by medical men who conduct dispensing practices. The holders of Certificate (b), the Minor Certificate, are eligible for the same appointments, and also have the advantage of being entitled to registration as chemists and druggists, and of being able to open shops. Hence the prospects of those who hold Certificate (b) would appear to be better than those of the holders of Certificate (a), since the outlook before them is wider. Among the holders of these certificates are a great many women, and it is not certain that the supply does not exceed the demand. Nevertheless, women seem to be adopting pharmacy with increasing frequency, and last year the winner of the Pereira Medal at the School of Pharmacy was a woman student. There is also an Association of Women Pharmacists (Gordon Hall, Gordon Square, W.C.), which would doubtless be ready to supply further details with regard to this occupation.

LETTERS, NOTES, ETC.

"THE HEIGHT OF CREBULITY."

W. H. B. writes with reference to the paragraph under this heading which appeared in the JOURNAL on April 24th: Will you kindly allow me to suggest the reason why the recipients of the "cock toles" also received "a bottle of hair lotion?" No doubt they would be very wild, and the "lotion" would point out to them the advisability of "keeping their hair on."

* * * *Haare lassen* (to shed hair) may be used figuratively as equivalent to "being fleeced." This seems to supply an explanation of the hair lotion.

ERRATUM.

In line 16 of the leading article on Antityphoid Inoculation (BRITISH MEDICAL JOURNAL, May 8th, p. 1140), for 0.8502, read 0.4802.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

A Clinical Lecture

ON

THE EARLY DIAGNOSIS OF CARCINOMA OF THE PROSTATE.

DELIVERED AT THE LONDON HOSPITAL.

BY C. MANSELL MOULLIN, M.A., F.R.C.S.,
SENIOR SURGEON TO THE HOSPITAL.

ONE of the unexpected consequences of the work that has recently been done in connexion with the treatment of enlargement of the prostate is the discovery that malignant disease of the prostate is very much more common than was formerly believed. In the English textbooks of ten years ago cancer of the prostate is described as being of rare occurrence, and the chief symptoms noted are intense pain and profuse hæmorrhage. As a matter of fact, it is unhappily very common, and in many instances there is neither a severe degree of pain nor profuse hæmorrhage until the disease is far advanced. Of the last fifty cases of enlargement of the prostate in which I have been consulted, no less than ten were certainly malignant, and I am afraid two more will prove to be so, though I cannot say definitely yet. My experience may be exceptional, I admit. I do not mean that 25 per cent. of all cases of enlargement of the prostate are due to malignant disease, but only 25 per cent. of those which were brought under my notice. The majority of patients with enlargement of the prostate never consult any one at all, and probably most of the cases that were sent to me came because it was thought there was something unusual about them. Both considerations, of course, reduce the proportion; but, after making full allowance, cancer of the prostate cannot possibly be described as very rare. Others, too, have found the same. According to Young, cancer of the prostate is present in one-seventh of the cases of enlargement in men over 50 years of age. Lewissohn of Heidelberg found 13 cases of malignant disease out of 143, while Albarran and Hallé calculate that it is present in approximately 14 per cent. I have only met with one case of sarcoma growing in the prostate itself, and that was in a boy ten years old, so that the following remarks apply solely to primary carcinoma. Secondary cancer, which is also not uncommon, introduces so many complications that I shall leave it upon one side for the present.

Cancer of the prostate is always of the glandular type. It may be either hard or soft. The former is much more common. In fact, I have only met with three instances of the latter, and Young, in his monograph on Cancer of the Prostate, in the *Johns Hopkins Hospital Reports*, does not appear to have met with any. The growth may originate either in a normal gland or in one that has already been the seat of enlargement for years past. In either case, it rapidly infiltrates the tissue around, flattening the outlying parts to some extent against the inner surface of the capsule, and only penetrates the capsule itself at a comparatively late period. The direction of the growth is almost always upwards, along the course of the ejaculatory ducts—which may be found plugged with columns of cancer cells—filling up the intervesicular space, and spreading from there along the lymphatics into the trigone of the bladder. From thence it grows outwards towards the walls of the pelvis on either side. The urethra may be compressed at an early date, or not, according to the position and direction of the growth, but it rarely becomes actually involved until late. The soft variety is an exception, as this very soon spreads into the neck of the bladder, sprouting out as a fungating, more or less villous mass. Two of the three cases under my care proved fatal from the bleeding that arose from this.

The internal iliac and then the other pelvic glands are the first to become infected. As these can hardly be felt, even when they are considerably enlarged, and not at all when the infection is only recent, it is very difficult to ascertain when this takes place. In many instances there is reason to believe that it is not till very late. Metastatic deposits, on the other hand, are sometimes

found exceedingly early, while the original growth is still quite minute, and are especially common in the long bones and ribs. An excellent instance of this, not by any means unique, is recorded in the *Archives of the London Hospital Pathological Institute*, vol. ii. p. 175. Deposits of carcinoma were found in the lumbar, iliac, and bronchial glands, pleural lymphatics, marrow of right femur and lumbar vertebrae, secondary to a growth in the prostate, which was only discovered by making a microscopic examination. The gland was in no degree enlarged, and exhibited absolutely no naked eye change on section. Further, no signs of infiltration could be detected in the surrounding tissues. The patient, who had been admitted into hospital for excruciating pains in the chest and limbs—so severe as to prevent him from standing—never complained of any urinary trouble until ten weeks before death, when retention suddenly occurred, followed by incontinence of urine and faeces.

The microscopic appearances in cancer of the prostate may be characteristic, but in many instances they are so varied and so complicated by those due to pre-existing enlargement and chronic inflammation that a very exhaustive examination is required before a definite opinion can be formed. There may be a large amount of stroma, with only a few elongated slit-like alveoli between the bundles, so that the whole is as hard as scirrhus; or there may be very little, and that of the most delicate description. The alveoli may be of the most irregular shape and size, and filled with cells until the central cavity is obliterated; or they may be perfectly uniform, lined with a single layer of cells, and enclose a rounded space as regular in shape as if the section had been made through a normal tubular gland. The cells may be cylindrical with a nucleus of moderate size near the base, or cubical, or quite irregular with nuclei of all shapes and sizes. There may be great intra-alveolar growths, indistinguishable from the proliferating intracystic growths so common in the hypertrophied gland, and in the same specimen there may be every gradation between the two extremes. In short, while in some cases the diagnosis with the microscope is perfectly straightforward, in others it is almost impossible, certainly from a single section, to make sure whether the growth is carcinoma, or merely one of those rapidly growing adenomata that occur so frequently in an enlarged prostate. A very good example of this difficulty is recorded by Young.¹ He describes how, in a case in which the cancerous process had grown down into the prostate, probably from one of the vesicular seminales, it was only after a second series of sections and repeated examination that it became evident that what had been taken to be adeno-carcinoma of the prostate was in reality alveoli, packed with epithelial and polynuclear cells, a process of inflammation, and not carcinoma. In several instances under my own care I have found the same difficulty. In many parts the growth appeared to consist almost entirely of tubules, perfectly uniform in shape and size, with no appreciable difference from the normal ones, yet spreading into and under the trigone of the bladder, and even between the muscular bundles. Nor could I find any evidence of infiltration of the stroma by epithelial cells. Albarran and Hallé have applied the term "epithelioma adenoid" to some of these appearances which suggest the beginning of malignant formation in lobules apparently purely adenomatous. Whether such a borderland as diffuse adenoma is advisable or not, it is quite evident that at present a considerable number of cases occur which are very doubtful in character: and some of which the one described in the *Archives of the London Hospital Pathological Institute* is an instance, in which a positive opinion is impossible without a prolonged investigation. Unfortunately this detracts considerably from the value of Young's proposal, that in doubtful cases a section should be made and examined on the spot, while the operation for removal is proceeding; for it is in just those cases in which the clinical diagnosis is most difficult that the microscope is most likely to fail.

The age of my patients ranged from 45 to 79 years, the majority being between 58 and 65. The duration of the symptoms before they came to see me varied from less than a month to over twenty years. This, of course, depended on whether the cancerous growth originated in a gland otherwise normal, or, as more frequently happens,

in one that was already the seat of some degree of enlargement. Whether the growth was hard or soft, the symptoms were the same in character as those present in the ordinary non-malignant form of enlargement—increased frequency of micturition; delay at the beginning, dribbling at the end; a certain degree of urgency; pain, which in the later stages sometimes became very severe, and hæmorrhage. The distinctive feature was the rapidity with which these symptoms progressed when once they had set in, and the degree of severity to which they attained in a very short time, without there being cystitis or any similar cause to account for it.

Increased frequency of micturition was present in them all. In some it had been present for years, in others it had begun quite recently; but there was this feature about it—a feature the development of which one of my patients who had already suffered from increased frequency for some time himself noted to me—that the disproportion between the frequency during the day and during the night was not nearly so great as it usually is in cases of simple enlargement, and that the act of micturition did not give the customary degree of relief. As a rule, if there is no cystitis or calculus in a case of enlargement of the prostate, the act of micturition is followed by a period of comfort, which lasts for a longer or shorter time. In carcinoma it is not; relief is not complete. The desire is always there, though it may be less immediately after the completion of the act, and this naturally leads to a very rapid increase in the number of times. A patient with non-malignant enlargement of the prostate has often risen once or twice every night for many years before the frequency becomes so great as to suggest the propriety of seeking advice. In malignant disease, whether it originates *de novo* or is consecutive to enlargement, the frequency often becomes as great in as many months.

Another point of some value in connexion with this is the effect produced by passing a catheter. The passage of a catheter for the first time in a case of enlargement of the prostate is always a serious matter, but unless there is some exceptional feature present, such as unusual difficulty causing hæmorrhage from laceration of the mucous membrane, it is not followed by any local irritation. The patient has not to pass water more frequently. On the contrary, perhaps because the bladder has been emptied more thoroughly than usual, he can often wait a longer time. This is not the case when carcinoma is present. Nearly always it will be found that in these circumstances there is a definite increase in frequency afterwards which only subsides at the end of twenty-four hours; and if an attempt is made to treat such a case by the habitual passage of a catheter the last thing at night, it will very often be found that the symptoms are aggravated rather than relieved. Much, of course, depends upon the exact position of the growth, but in no case is it very long before the hyperæmia that surrounds a growing focus of carcinoma succeeds in reaching the urethra, and making its lining membrane more sensitive.

Pain, when it occurs in association with enlargement of the prostate, is always serious. In the ordinary form of enlargement there is no pain. When it does set in, it is due to the presence of some complication, such as cystitis or calculus. Sometimes under these conditions pain may be very severe, but whatever the degree it is always associated with the act of micturition, and almost invariably is described as shooting down the urethra to the end of the penis. When the enlargement is due to chronic inflammation, whether tuberculous or gonorrhoeal, pain is not uncommon, but this too is associated with micturition, and is only severe when there is ulceration at the neck of the bladder. In these cases, however, there is often besides this a sense of uneasiness and fullness in the perineum. The patient will volunteer the statement that he often has a certain amount of discomfort there, and that this is relieved by firm continued pressure, but it is rarely spoken of as actual pain. In cancer, so long as the growth is small and placed so that there is some thickness of normal prostatic tissue around it, there may be no pain. As, however, the growth enlarges and begins to stretch, or still more to involve the capsule, pain seldom fails to make itself felt. But this pain differs in many respects from that which is present in cases of cystitis or calculus. It is constant day and night, and is referred to something deep in the perineum, almost in the rectum, so that the patient

imagines there is something pressing forcibly against the wall of the bowel. It bears no relation to micturition, and though it may spread down the urethra even to the glans, it is not confined to that region, nor felt most severely in it. Later still, when the malignant growth has spread beyond the capsule, and has begun to involve the structures around, the pain may become agonizing, radiating down all the branches of the sciatic plexus. One patient came to consult me because of sciatica, which nothing seemed able to cure, and which was growing worse every day. It was bilateral, but worse upon the right side, and was continuous night and day. The prostatic symptoms from which he suffered he regarded as of no importance, but on examining him per rectum, the cause was only too plain. There was an extensive growth of stony hardness spreading up from the prostate, and firmly fixed to the wall of the pelvis on either side. Pain such as this is characteristic, but unfortunately when it occurs the diagnosis is usually already obvious, and the only treatment possible is palliative.

Hæmorrhage is not an early symptom of carcinoma of the prostate, and it is such a common occurrence in connexion with the simple form of enlargement, that it is only under special circumstances that it can be considered a symptom at all. In the hard variety of carcinoma, which is the most common, there may never be any hæmorrhage. It is usually present when the growth has ulcerated, but the quantity is rarely large. As usual when the source of the bleeding is at or near the neck of the bladder, the blood precedes, or more often follows, the stream of urine. It is not mixed with the urine, but this is equally true of many other lesions in the same locality. Hæmorrhage is only characteristic when it is causeless, frequent, and profuse, like that which occurs in villous tumour of the bladder. The soft form of carcinoma, when the growth has spread into the bladder, resembles this in many ways. It is quite as vascular, and the walls of the vessels are equally delicate. The least injury, even the contraction of the bladder wall around it, is sufficient to make it bleed. When the bleeding once begins, it is almost impossible to check it, for everything that is done only injures another portion of the growth, and makes that bleed. In two out of the three cases of soft carcinoma under my care, the hæmorrhage proved fatal, in one directly, in the other from loss of strength entailed by the continued drain of blood.

The physical signs in the early stages of carcinoma of the prostate are vague and ill-defined. If the growth originates deep in the substance of a gland that is enlarged already, they may be altogether wanting for a time. As in the case I mentioned before, it sometimes happens that they remain latent throughout. As a rule, however, by the time the symptoms have become sufficiently severe to induce the patient to seek advice, the physical signs are plain and well marked. The stony hardness of the prostate, when examined from the rectum, is the most striking feature of the ordinary variety of carcinoma. In the early days this may be limited to one or more areas, the intervals between which are still soft and elastic. Later, these areas fuse together, and the whole gland becomes intensely hard, inelastic, and unyielding. In chronic prostatitis, and in that form of fibroid enlargement which resembles it so closely, the gland is often harder than natural, but it very rarely attains the peculiar stony feel which characterizes the common form of carcinoma. The finger can make no impression upon it. The soft variety of cancer is entirely different. I have not met with any instance in which the growth was still limited to one portion of the gland. In none of the cases under my care was there any material increase in size on rectal examination. The surface was uniformly soft and pulpy, not elastic or fluctuating; and the margins were ill-defined, so that the upper border of the gland could not well be distinguished from the adjacent portion of the trigone. The gland was flatter than normal. It had quite lost its natural rounded contour, and instead of meeting the finger at once, as it entered the rectum, the prostate had, as it were, to be felt for. This, of course, is what might be expected from the growth of a soft carcinoma enclosed on all sides, except towards the bladder, in an unyielding fibrous capsule. The firm normal tissue of the prostate is replaced by a much softer substance, which spreads in the direction of least resistance, and leaves the capsule unsupported.

The shape of the prostate when it is the seat of malignant disease may be as characteristic as the consistence, but here again the same reservation must be made. The alteration may make its appearance early and be well marked, or there may be no alteration at all, even to the end. In the simple form of enlargement the gland, as it increases in size, pushes all the surrounding structures to one side. It swells out towards the rectum as an elastic rounded mass, very variable in shape, perhaps studded on the surface with bossy elevations, differing from the rest in consistence, but the contour remains well defined, even in the small fibroid variety. The upper border is convex from side to side, or, if concave from the extreme upward growth of the two lateral lobes, it is steeply cut and rounded off. At the sides the margins of the gland are clear and distinct. The trigone beyond is free, or if there is a growth spreading into it, it forms a defined invading mass, not a general infiltration. Malignant disease, on the other hand, infiltrates everything. Almost always the first part to become affected is the tissue surrounding the ejaculatory ducts, so that what feels to the finger like a horn of growth spreads upwards on either side towards the vesiculæ seminales, and at last spreads into them. Then the intervesicular space becomes thickened—this is much better appreciated when there is an instrument in the bladder at the same time. In a little while the change involves the tissues on either side and around the base of the prostate. The margins of the gland can no longer be defined. Hard cords can be felt running up towards the walls of the pelvis, and very soon the prostate becomes fixed and immovable. In the later stages of the disease, when it is advanced, the diagnosis is easy. In the earlier ones the difficulty may be very great; and, as it is imperative to make certain whether cancer is or is not present, it is always advisable to examine the patient under an anaesthetic in the lithotomy position, while firm pressure is being made over the pubes, so as to force the prostate down into the perineum.

The cystoscope is, unfortunately, not of much service in the early diagnosis, though it gives valuable information later. Much more can be learnt from the passage of a catheter, especially if a rectal examination is made at the same time, so as to form some conception of the condition of the intervesicular space.

It is always a matter for gravesuspicion if the characteristic symptoms of prostatic enlargement have made their appearance suddenly—within a twelvemonth, for example—and if on passing a catheter in expectation of finding a large amount of residual urine, an ordinary olive-pointed instrument slips in easily and only a few drops come away. It means that all the ordinary symptoms of prostatic enlargement are present without any overgrowth of the median portion or of the lateral lobes to account for them. Perhaps this—the disproportion between the symptoms of which the patient complains and the physical signs that are found on examination—is the most significant point of all in the early diagnosis of cancer. From what the patient says about himself, a well-marked case of prostatic enlargement with residual urine is expected. What is found is a very slight degree of enlargement with nothing that will explain the frequency of micturition. If in such a case the patient complains of a constant pain in the perineum; or if there is a nodule of stony hardness in the prostate, or an extension of the growth towards one of the vesiculæ seminales; or if when a sound is introduced into the bladder and the beak is reversed, there is definite thickening of the intervesicular space, the diagnosis hardly admits of doubt.

With regard to the question of treatment there is very little to be said. Suprapubic enucleation should never be attempted for cancer. Except by accident the whole growth cannot be removed in this way. The operation is not one suited to cancer. Recurrence *in situ* is almost invariable, and from thence the growth spreads to the suprapubic wound, or involves the orifices of the ureters. The only method that holds out any hope of success is that devised by Young, in which the whole of the prostate with its capsule intact, the vesiculæ seminales, and the adjacent portion of the neck of the bladder are removed *en masse* through the perineum.

An Address

ON

THE DIAGNOSIS AND TREATMENT OF SOME COMMON INFLAMMATORY AFFECTIONS OF THE EYE.

FROM THE STANDPOINT OF THE GENERAL PRACTITIONER.

DELIVERED BEFORE THE STRATFORD DIVISION OF THE BRITISH MEDICAL ASSOCIATION,

BY E. E. HENDERSON, M.B., B.C., F.R.C.S.,

OPHTHALMIC SURGEON TO THE WEST HAVEN AND EAST LONDON HOSPITAL.

In discussing the differential diagnosis and treatment of the common inflammatory affections of the eye from the standpoint of the general practitioner, I propose to limit myself to three affections—namely, conjunctivitis, iritis, including cyclitis, and acute glaucoma.

All three are accompanied by at least two of the cardinal symptoms of inflammation—redness and pain—with the addition of one other, the peculiar property of the region affected, photophobia. This last symptom is probably somewhat inaccurately named, as the nerve affected is the fifth nerve, which is not sensitive to light. The shrinking from light displayed is due more to exposure to the air and variations of temperature than to any direct action of the light rays.

Well marked cases of these three affections should present little difficulty in diagnosis, but in the early stages, before some of the more characteristic symptoms have had time to make their appearance, a most careful examination of the affected organ may be necessary before arriving at a satisfactory conclusion, and it is to be remembered that any mistake in treatment may be followed by the most disastrous consequences.

Recognition of Ciliary Injection.

In the differential diagnosis between these three affections the presence or absence of ciliary injection plays a most important part, I therefore propose briefly to recapitulate the points that distinguish ciliary from conjunctival injection.

In conjunctival injection there is present a superficial network of larger and smaller vessels, readily movable with the conjunctiva. The colour of the injection is a vivid scarlet or brick red, and cannot, owing to the freedom of the collateral circulation, be made to fade on pressure with the finger. This form of injection is most intense on the lids, and diminishes towards the cornea.

Ciliary injection, on the other hand, occurs as a rose-red or pale-violet zone surrounding the cornea, in which it is impossible to recognize clearly the individual vessels, and which is not movable with the conjunctiva. In the more severe cases of ciliary injection a coarse network of vessels at a greater distance from the cornea is also visible; these may be distinguished from conjunctival vessels by their hazy appearance, violet colour, and immobility relative to the conjunctiva. Owing to the numerous anastomoses between both sets of vessels, severe inflammatory affections of the uveal tract are always accompanied by a certain amount of conjunctival injection, but the essential point is to recognize the existence of the ciliary injection, as this always indicates inflammation of some structure deeper than the conjunctiva.

Symptoms and Treatment of the Ordinary Forms of Conjunctivitis.

The subjective symptoms will naturally depend on the severity of the case, but it may be stated that severe pain is only met with as the result of some complication, such as ulceration of the cornea. Complaint will be made of discharge from the eyes, with itching and burning sensations, generally becoming worse towards night. Vision is interfered with by the passage of flakes of discharge in front of the cornea. The discharge tends to glue the lids together during sleep.

On examination the surgeon finds that conjunctival injection is present, confined at first to the palpebral surface, and most marked in the lower cul-de-sac.

For clinical purposes the various forms of conjunctivitis may be arranged in four main groups, in accordance with the presence or absence of the following symptoms:

1. The nature of the discharge, muco-pus or pus.
2. The presence of a membrane.
3. Chronic irritation with little or no discharge.
4. A miscellaneous group, in the course of which ulceration and vascularization of the cornea are prone to occur, and not characterized by the presence of discharge.

In any case in which discharge is present a bacteriological examination should be made. Its results, indeed, are frequently disappointing, nor is this surprising when the exposed situation of the conjunctiva is considered. Nevertheless, the great importance of the recognition of the presence of the gonococcus, streptococcus, or the bacillus of diphtheria, makes the examination of the discharge or membrane of great importance in all the more severe cases.

There are three main principles underlying the treatment of all varieties of conjunctivitis: First, the due recognition of the contagious nature of the discharge. This must be impressed on the patient and his friends or attendants. Nothing that has been contaminated by the discharge must be allowed to be used by any one else. Should some of the discharge be conveyed by a splash or in some other way to the eye of an attendant or surgeon, it must be immediately removed by free irrigation with 1 per cent. boric acid lotion, and the irrigation should be followed by the instillation of a few drops of 20 per cent. protargol. In the more severe purulent cases the patient should be completely isolated, and steps taken to protect the second eye, should only one eye be affected when the patient comes under observation.

The second main principle is to provide for the due removal of all secretion, and to prevent the gumming of the lids, which by closing the palpebral fissure converts the conjunctival sac into a closed cavity.

Thirdly, we attempt to destroy the vitality of the micro-organisms that are producing the disease by the application of certain chemical agents.

Acute Purulent Ophthalmia.

The most frequent cause of purulent ophthalmia is the gonococcus, and if early treatment is not successfully adopted the loss of the affected eye is an event only too probable.

If, as is frequently the case, only one eye is affected, the surgeon should first examine the apparently sound eye, and should this show no sign of inflammation, take immediate steps to protect it from contamination. This is best done by the use of a Buller's shield, but until this can be procured or improvised the sound eye can be efficiently protected by means of cyanide gausee tissue securely fixed with a bandage. When a Buller's shield is employed, constant attention must be directed to the strapping over the side of the nose, and a vent-hole should be made near the outer part of the eyebrow by inserting a small piece of drainage tube. The shield must not be removed until all discharge from the affected eye has ceased. The next step is the careful removal of all discharge from the affected eye by gentle irrigation with warm 1 per cent. boric acid lotion. The surgeon or attendant should always wear protecting goggles while engaged in the treatment of any of these severe ophthalmias. As soon as the eye is sufficiently clean the lids should be gently separated and the cornea examined. Should there be any doubt as to the presence of any ulceration, a drop of fluorescein solution is instilled. If the cornea is as yet unaffected, the lids are gently inverted without allowing anything to come in contact with the cornea—the slightest abrasion being sure to become infected, with disastrous consequences to the eye—and painted with a 2 per cent. solution of silver nitrate by means of a wisp of absorbent cotton wrapped round a glass rod. If the conjunctiva is very brawny and oedematous, this painting had better be omitted. There is no necessity to neutralize the excess of silver solution; it is sufficient to mop the conjunctiva with a pledget of wool.

The patient is kept in bed and provided with some absorbent cotton, and a basin of warm boric acid lotion, and instructed to wipe away the discharge as fast as it is secreted. Every hour or two during the day and at least

every four hours during the night the conjunctival sac is thoroughly irrigated with the same lotion from an undine by the attendant. A little boric acid ointment should be smeared on the lids to prevent them from sticking together.

The silver application should also be repeated daily, the strength and frequency of the applications being gradually diminished as the case improves.

If the cornea becomes affected, 1 per cent. atropine should be instilled every four hours, and if the discharge is still copious and an actual ulcer has made its appearance, 2 per cent. silver nitrate solution should be stippled into the base of the ulcer, but if the discharge has nearly ceased, cauterization with pure carbolic or the galvano-cautery will be advisable. If the ulcer is obviously about to perforate, as shown by the bulging of Descemet's membrane, a small perforation should be made so as to allow the aqueous to escape slowly, and thus prevent a large perforation with prolapse of iris. The later treatment of eyes in which perforation of the cornea has taken place and left a prolapsed iris adherent to the cornea falls outside the scope of this paper; it is sufficient to state that unless operative steps to free the iris or make an iridectomy are taken the eye will be lost through secondary glaucoma.

Ophthalmia Neonatorum.

Ophthalmia neonatorum, which is also in the majority of cases due to the gonococcus, demands similar treatment, but as both eyes are always affected there is no need to protect one. This affection is not so severe as the disease in adults, and if the case is seen before any affection of the cornea, a successful result should usually be obtained. A unilateral discharge of pus is occasionally met with in infants, due to an infection of the lacrimal sac. If keeping this squeezed out and the eye cleansed with a boric acid lotion fails to effect a cure, it is generally easily remedied by the passage of a fine lacrimal probe down the nasal duct, after dilatation of the canaliculus.

The first examination of an infant with ophthalmia neonatorum must be conducted with extreme gentleness, and should there be any reason to suspect that the cornea is affected it is safer to administer a general anaesthetic than to run any risk of increasing the damage owing to the struggles of the patient.

This affection is still, I regret to say, one of the commonest causes of irremediable blindness, and I am convinced that if Credé's method of applying silver nitrate to the eyes of all newly-born children, when there is any reason to expect the possibility of infection, was systematically carried out, it would become one of the rarest.

Muco-purulent Ophthalmia.

Muco-purulent ophthalmia may be due to a great variety of organisms, but the general principles of treatment conform to the account just given. It is generally unnecessary to repeat the application of silver, but the course of the affection is undoubtedly shortened by painting the lids with a 1 per cent. solution of silver nitrate at the first visit. The pain of the application may be much diminished by the use of cocaine, but this is inadmissible in the purulent affection from its damaging effect on the corneal epithelium; if in addition the lids are once more everted a quarter of an hour after the application, and the coagulated epithelium gently removed with some absorbent wool, no lasting irritation will be caused.

A lotion of 1 per cent. boric acid with 0.5 per cent. sulphate of zinc and some boric acid ointment are prescribed. The patient is instructed to lie on his back with the head on one side so that a little pool of lotion can be retained between the nose and the closed lids. A dozen drops are then placed in this position by means of a pipette, the patient meanwhile keeping the lids closed. He then with the hand draws the lids away from the globe, so that the lotion runs well into the fornices. After drying the superfluous lotion with some absorbent wool, a little of the ointment is smeared on the lid margins. This should be repeated half a dozen times a day at first, gradually diminishing the number of applications as the discharge ceases. If during the progress of the disease an ulcer of the cornea makes its appearance, it should be treated in the way already described, but under no circumstances should an eye in which discharge is present be covered with any dressing.

Membranous Conjunctivitis.

Nearly all the micro-organisms that cause mucopurulent ophthalmia may at some stage of their course, in suitable subjects, produce a membrane. It is, however, chiefly on account of the diphtherial and streptococcal affections that it is necessary to separate this class of case. Membranous conjunctivitis occurs chiefly in children, and shows all grades of severity, the more severe cases being accompanied by considerable constitutional disturbance. The pre-auricular gland is swollen, and even occasionally suppurates. Although a bacterial examination should be made in every case it is not advisable to wait for the results of this before using antitoxin. Until a definite bacteriological report has been obtained isolation should be insisted on exactly as in dealing with faucial diphtheria. The local treatment is exactly the same as that for purulent ophthalmia, but painting with silver is not to be resorted to.

Chronic Irritation of the Conjunctiva with little or no Discharge.

In nearly all these cases the source of irritation will be found in some error of refraction or muscular anomaly. If proper correction of these defects does not entirely remove the symptoms, I have seen considerable improvement result from the instillation twice daily of a 15 per cent. solution of protargol. It is to be noted that this or any other preparation of silver is on no account to be used for more than fourteen days for fear of producing silver staining of the conjunctiva.

The mild catarrhal conjunctivitis to which gonty subjects are liable is not benefited by energetic local treatment. Rest and protection from wind and dust, with in some cases the occasional instillation of a drop or two of a solution of cocaine (0.5 per cent.) are the best methods of dealing with this affection.

Angular Conjunctivitis.

There is one other form in this group to which I wish to draw attention, and that is angular conjunctivitis. This has two peculiarities. First, it is almost the only form of conjunctivitis in which the clinical appearance is characteristic of the special organism at work (the diplobacillus of Morax-Axenfeld); and, secondly, it is almost the only form of conjunctivitis which in the absence of suitable treatment tends to persist indefinitely. The inflammation is confined chiefly to the lid margins, with accompanying excoriation of the skin, especially marked at the canthi. The boracic lotion combined with zinc sulphate, applied as described in the treatment of mucopurulent ophthalmia, readily effects a cure.

Trachoma and Phlyctenular Ophthalmia.

The only common forms of conjunctivitis in my fourth group are trachoma and phlyctenular ophthalmia. Time will not allow of the discussion of the methods of treatment suitable for these diseases and their complications.

Tubercle and syphilis rarely attack the conjunctiva. Inasmuch as when they do they usually produce ulceration, they should not be confused with the forms already described. Finally, it must be remembered that certain drugs, of which the chief are atropine and eserine, may occasionally produce a condition of the lids that resembles erysipelas.

Iritis.

The iris, representing as it does the most anterior portion of the uveal tract, seldom passes through an attack of acute inflammation without some slight involvement of the ciliary body. In cases in which this involvement is very severe it is customary to speak of irido-cyclitis, but it must be understood that there is no very hard and fast line to be drawn between the two diseases.

Iritis is usually attended with very severe pain, and it is this which usually brings the patient before the surgeon.

On examination, it will be seen that ciliary injection is present, the pupil is constricted, and its edge is irregular. The reaction to light is sluggish, even before any synechiae have had time to form, and the colour and texture of the iris is altered. As during the acute stage iritis is usually unilateral, these points are easily determined by comparison with the other eye. Hypopyon and hyphaema are rarely met with in simple iritis. If there is much involve-

ment of the ciliary body, the altered condition of the intraocular fluid manifests itself by the presence of deposits on the back of the cornea. As a result of the albuminous nature of the aqueous humour in these inflammations, filtration is so seriously interfered with that the intraocular tension may be so increased as to endanger the eye in the absence of operative interference. These symptoms, compared with my previous remarks on conjunctivitis, sufficiently differentiate the two affections.

Before discussing the diagnosis of iritis from glaucoma I propose to say a few words about the etiology and treatment of iritis. Sepsis, syphilis, and tubercle are the main causes of iritis. Sepsis—under which heading I include gonorrhoea—is by far the most important of the three. Apart from gonorrhoea, the most frequent source of septic infection is to be found in the mouth, in the shape of pyorrhoea alveolaris and soft caries of the teeth. These affections are, as is well known, responsible for other diseases, and, as Hunter pointed out, individual patients exhibit great variations at different periods in the degree of their immunity. Iritis is usually accompanied in this class of case by cyclitis, and it is not uncommon to meet with a patch of inflammation in the choroid. The gonorrhoeal type usually shows much vascular engorgement, and is prone to the early formation of synechiae.

Syphilitic iritis manifests itself in two forms. The commonest is a simple plastic iritis usually seen before the end of the first year. This form may also be seen in congenital syphilis, and usually accompanies interstitial keratitis. A second and much rarer form is seen as a late secondary or early tertiary form, and is characterized by the formation of yellowish-red nodules near the pupillary and ciliary borders of the iris but not in the intermediate zone.

Tuberculous iritis occurs in a miliary and a conglomerate form. In appearance it resembles the late form of syphilitic iritis, from which it is to be distinguished by the history and the failure of specific treatment. There is also rather less general iritis.

I have not mentioned rheumatic iritis, and must confess to a certain amount of disbelief in its existence. It has never been found to accompany acute rheumatism, and the rheumatoid pains complained of may well be due to a mild septic infection.

The treatment of iritis must be local and general. The essential of the local treatment is to dilate the pupil and to keep it dilated. For this purpose I am in the habit of using atropine ointment, 1 per cent. combined with 0.5 per cent. cocaine, for the first three days. The cocaine acts as a direct stimulant to the sympathetic nervous mechanism of the pupilo-dilator fibres, and so increases the effect of the atropine, which acts chiefly by diminishing the hyperaemia and paralyzing the constrictor pupillae. The use of cocaine is deleterious to the corneal epithelium, and should be discontinued as soon as the maximum dilatation is obtained. The ointment should be employed every four hours at first, later, as the disease yields to treatment, atropine without cocaine, applied two or three times daily, will suffice to keep the pupil dilated. Hot fomentations or bathtings, or dry heat supplied from a Japanese muff warmer, diminish the pain and act beneficially. In all severe cases a couple of leeches applied to the temple are of great service. If high tension persist, paracentesis should be done, and, if necessary, repeated. The general treatment is that of the condition to which the iritis is due. All sources of sepsis, and more especially the mouth, must receive energetic treatment.

The treatment of the sequelae in the shape of numerous synechiae is mainly operative, and the discussion of this point and the value of prophylactic iridectomy in recurrent iritis would occupy too much time.

Acute Glaucoma.

The disease with which acute glaucoma is most liable to be confused is iritis, and, as the treatment necessary for the latter—namely, the dilatation of the pupil with atropine—would infallibly destroy an eye affected with glaucoma, it is evident that the diagnosis is of the greatest importance.

What are the main points of difference?

1. *History.*—In even the most acute cases of primary glaucoma there is usually a history of previous symptoms

in the shape of transient attacks of pain accompanied by misty vision, with haloes round the lights. The acute attack is accompanied by very severe pain, often causing actual vomiting, and therefore liable to be mistaken for a bilious attack. The onset is always sudden, frequently associated with some condition, such as alcoholic indulgence, that leads to raising of the general blood pressure. Vision deteriorates with such rapidity that at the end of a few hours hand movements only are distinguished.

2. *Objective Signs.*—The eye is intensely congested with marked ciliary injection. The cornea is steamy and defective in sensibility. The anterior chamber is shallow. The pupil is semidilated, with regular outline, generally rather oval in shape, with the long axis vertical. It will be remembered that in acute iritis the pupil is generally small, with irregular outline. Finally, the intraocular tension is very considerably increased. Examination of the other eye may show a cupped disc.

If due attention is paid to these points, there should be no difficulty in the diagnosis of ordinary primary acute glaucoma. The cases in which difficulty is found are those of glaucoma secondary to cystitis or to the obstruction to the intraocular flow due to adhesions of the iris. In these the smallness and irregularity of the pupil, combined with the deep anterior chamber, and possibly the presence of punctate deposits on the cornea, will generally indicate the nature of the complaint.

In all cases of acute primary glaucoma, iridectomy should be performed as soon as conveniently possible. It would take us too far to deal with the proper method of performing this operation, nor do I think it is an operation that should be undertaken by any one who is not likely to have the opportunity of performing more than one or two. It is certainly one of the most difficult that the ophthalmic surgeon is called upon to do.

Is there anything to be done while arrangements for operating are being made? Hot bathing, instillation of a solution of eserine sulphate 1 per cent. every two hours may be successful in reducing the tension; at any rate they should be tried, and a brisk saline purge administered. In all cases in which the intraocular tension is much raised, I prefer immediately before doing an iridectomy to first lower the tension in the posterior chamber by puncturing the eye behind the equator with a Graefe knife. This obviates one of the worst risks of the operation, namely, the dislocation of the lens forwards as a result of the sudden lowering of the tension in front. Where possible this may well be done a few hours before the actual iridectomy. It is simple of performance, and cocaine affords sufficient anaesthesia. For the iridectomy itself a general anaesthetic will be required.

Remarks

ON

PARTIAL THYROIDECTOMY,

WITH SPECIAL REFERENCE TO EXOPHTHALMIC
GOITRE, AND OBSERVATIONS ON 113
OPERATIONS UNDER LOCAL
ANAESTHESIA.

By T. P. DUNHILL, M.D., B.S.,

JUNIOR SURGEON TO IN-PATIENTS, ST. VINCENT'S HOSPITAL,
MELBOURNE.

During the past twenty months I have performed the operation of partial thyroidectomy 113 times, in the great majority of cases for exophthalmic goitre. During that time, watching the cases before and after operation—sometimes through successive operations—certain conclusions have forced themselves upon me.

This question, "Should exophthalmic goitre be treated surgically?" has been answered by the patients themselves in about one half of the cases, and by medical practitioners in the other. Every case had been treated medically until it had become apparent to the physician or the patient that improvement was not taking place. In many of the cases the condition of the patient had become extremely critical.

In cases which are definitely not improving under medical treatment there can be no question as to the

necessity for surgical interference, if one believes that the disease is a thyrotoxicosis, and that the removal from the individual of a large part of the poison-producing body will enable a state of equilibrium as regards the output of thyroid secretion to be regained and maintained. While not for a moment minimizing the risks of the operation (which are very great, and may easily lead to disaster), it may be said that the operation is as safe as any major operation in surgery. I believe that there is no need to fear death either at or following operation, provided it is performed under local anaesthesia.

Difference in Type.

Differences in degree and type with corresponding differences in character and rapidity of response to operative treatment may be noted, and I have begun to classify cases of thyrotoxicosis from the point of view of operation as follows:

1. Those cases which have all the classical signs—namely, goitre, exophthalmos, tachycardia and palpitation, and tremor—but are still able to do some work. The tachycardia is constant and palpitation frequent, especially with a little extra exertion. They may look well or be greatly emaciated, but they have no organic heart lesion and no oedema. Frequently there is complete amenorrhoea. Some patients suffer much from diarrhoea. The appetite is usually ravenous.

2. Cases which have all the classical signs but in which the symptoms have progressed until organic changes have taken place in the heart muscle; or there is dilated heart with inefficient valves. The patient may have an irregular, intermittent pulse. Oedema is present, perhaps only a little on walking about, perhaps constant in whatever part of the body is dependent. In one case it was also marked in the face, where it had been present for some months, on the side which was lowermost during sleep. In other cases there has been simply oedema of the feet and legs on walking, the oedema disappearing on lying down.

3. Cases in which the signs are incompletely developed, but often presenting great toxæmia. There is very little enlargement of the thyroid gland but very marked tachycardia and a constant sensation of smothering. Exophthalmos and characteristic tremor are not present. One cannot call this class of case "exophthalmic goitre"; the term "thyrotoxicosis" is much more suitable.

4. Cases sometimes described as secondary exophthalmic goitre, in which from the history it would appear that the goitre preceded the thyrotoxic condition. The thyroid gland is usually very much enlarged, and the enlargement may be central or unilateral. If the patient is put to bed, it is found that tachycardia is not always present, but palpitation supervenes so constantly on the slightest exertion that the patient is practically invalided. Owing to the size of the goitre and the long period during which it has been present, there is generally some pressure on the trachea, causing dyspnoea on exertion, and often during sleep—frequently, indeed, preventing sleep. There is sometimes some prominence of the eyes, and there is usually tremor.

Response to Operative Treatment.

Cases of the first class respond rapidly and almost completely to operative treatment. They have not lost their recuperative power, and, though they are ill and have all the classical symptoms of the disease, when the poisoning body is removed they at once feel a tremendous difference in themselves, and in a few weeks are almost—I might say completely—well. One woman says she can now do all her household washing and ironing, but scrubbing causes some slight return of the palpitation. Another cooks for her husband and two children, does all the household work, and, as well, teaches six music pupils. Two others, who had been completely invalided, are farmers' wives; each does the housework and a great deal of work incidental to the farm as well. This is the stage at which the operation should be performed, as practically complete recovery can be promised, and the period of convalescence is short.

If the patients have gone beyond this stage and belong to the second class—if there are objective signs of heart failure—the rapidity and completeness of cure varies. All the textbooks and articles which I can find speak of cases of this class as too advanced for operative interference presumably for two reasons: First, because the patient

are too ill to be cured; and, second and chief, because the operation in such cases would be too dangerous. The statement that they are too far advanced for operation is not true. I would go so far as to say that no case, unless almost moribund, is too far advanced to obtain immense relief from operation. The extent of relief is in inverse ratio to the extent of the organic heart lesion. Under local anaesthesia, the danger of the operation, even in the most advanced cases, is practically *nil*. Sometimes it is most difficult to tell whether or not there is actually organic heart disease. I have seen a case with oedema of the feet and legs, with the apex beat outside the nipple line, with markedly irregular pulse, with eyes so prominent that she had suffered from corneal ulceration twice, and who had the greatest difficulty in getting to town from the western district on account of the oedema and dyspnoea. This patient left the hospital with a regular pulse of 60. She is a farmer's wife, and now does her own housework, and writes me that she always feels well. One would have felt certain that this woman had myocarditis with a permanently damaged heart.

The most that cases in this class can hope for is great improvement without absolute cure, but it is quite worth while to operate to obtain this result, since great relief can always be promised. Local anaesthesia is essential. The following is a good example of the relief of symptoms:

The patient, a nun, had been under constant medical treatment for three years, but had grown steadily worse. When I saw her the face was asymmetrical with dependent oedema on the side on which she had been lying; the lower limbs also were oedematous. The pulse was most irregular and rapid. She had a large three-lobed goitre, and suffered with neuralgic pains at the apices of the lateral lobes and up into the ear, which prevented sleep. The other symptoms were those usual in a bad case of exophthalmic goitre. It was the oedema and the pulse which gave the interest to the case from the standpoint from which we are now viewing it. I kept her in hospital three weeks, and then sent her back to her convent. In the meantime I operated on another nun from the same convent, who had been ill with goitre for twenty-two years. Then the first nun, recognizing the risks of operation, wished to be operated upon. I removed the right lateral and the middle lobe, under local anaesthesia, without difficulty, and the patient was never once in danger to life as the result of the operation. Before operation she was completely invalided, but since she has taken long walks and has made a trip to Tasmania, visiting several convents there. The pain in the ears and upper neck region has disappeared, and all throbbing has gone. Her pulse, which was 120 to 130, is now between 80 and 90; it is still irregular, but quiet. There is oedema now only after long walks, and only in the feet. With a little care, she lives a happy life.

In a number of cases there is slight degree of oedema of the feet, but the heart beats regularly though fast—cases in which there is some acute dilatation, but apparently no gross organic change in the myocardium. These patients recover practically completely, but the period of convalescence is more prolonged than in cases in which there is no cardiac dilatation.

A good instance of this type is a lady who saw me in May of last year, and who arranged to be operated on. She was quite a typical case. On her way to Melbourne for the operation she heard of a case that had died after operation under general anaesthesia, and she at once went back to her home in the country and stayed there for three months. She then came to Melbourne again because she was rapidly becoming worse. She could not then get up the steps to my room. Her feet were oedematous; she had delirium cordis, and she was very ill. I removed the right lobe, the isthmus, and the lower pole of the left lobe at one operation. Her pulse slowed down, and all the objective signs improved, but she remained very weak and sweated profusely for six weeks before she felt much improvement. Then in the sixth week she gained 4 lb. in weight, all the sweating stopped, and from that time improvement was continuous and rapid.

The third class of case, with small thyroid gland, no exophthalmos, marked tremor, intense tachycardia, and constant smothering sensations, I regard as being the worst type to handle. The symptoms, which are out of all proportion to the enlargement of the gland, may indicate that thyrotoxicosis is a dysthyroidea and not a hyperthyroidea, an altered secretion and not simply an excessive secretion. In this class removal of half the gland does not give the certain relief of symptoms that it affords in typical cases. It seems as though even a small remaining portion of gland tissue pours out a secretion of such virulence that it is still able to poison the nervous system. The number of cases of this class is really very small.

With regard to cases without apparent enlargement of the thyroid gland, it must be remembered that not infrequently there is a very large lobe, the greater part of which is behind the upper end of the sternum, and the inner end of the clavicle and first rib. In two patients, one male and one female, it was practically impossible to detect enlargement of the gland, yet at the operation the enucleating finger was in contact with the second rib posteriorly, and in each case a large retrosternal goitre was removed.

The fourth class, described by some as secondary exophthalmic goitre, consists of cases in which the nervous symptoms are secondary, not primary, as the goitre precedes the heart irritability.

As a typical example of this class I would instance a nun in whom the goitre had been present twenty-two years. She had received constant medical attention. During the latter years she was practically invalided through palpitation, tremors, and sleeplessness. She was afraid of operation, as its severity had been frequently pointed out to her. A large central retrosternal goitre was removed. She was out of bed on the sixth day; within three months she was managing, and is still managing, a large orphan asylum.

When to Operate.

Every case should be treated medically for, say, three months, and if there is continuous improvement which shows definite signs of going on to complete cure, medical treatment should be persevered with. I have had three such cases, and I did not operate, although the patients placed themselves unreservedly in my hands.

A practitioner who advises against operation in any case which is not gaining ground, or which is losing ground, is undertaking a large responsibility. Nor is the operation to be regarded as a last resort. If a patient is kept under medical treatment until it is obvious that she is going to die unless some miracle be performed, her chances of ultimate complete recovery have been taken from her. Operation should be performed as soon as it is recognized that the patient is not improving, and before she has lost so much ground that she will require much nursing back to health after the cause of the disease has been removed. At the same time, it should be clearly recognized that it is practically never too late to operate, and that the operation in itself need never prove fatal if performed under local anaesthesia.

Local Anaesthesia.

In my opinion local anaesthesia governs the whole question as to the safety or otherwise of the operation for exophthalmic goitre. The underlying causes of death at or after operation are too ill-defined for us to be able to tell which cases will and which will not stand general anaesthesia. Under general anaesthesia the operation cannot be recommended as safe. Under local anaesthesia it may be recommended as perfectly safe unless the patient be moribund. In 88 operations for exophthalmic goitre I have had only one death, due to causes which will be explained later, and which need not occur again. I know of 54 deaths which have taken place during the last year in cases operated on under general anaesthesia.

There are many other reasons why local anaesthesia should be employed. Careful as I have been to avoid the vicinity of the recurrent laryngeal nerve, on one occasion the patient suddenly lost her voice and could only whisper. I at once removed all the artery clamps I had applied, and in a few moments she spoke naturally. I believe that if the patient had been under general anaesthesia a silk ligature would have been tied tightly around the nerve. In this instance the forceps had been applied to stop some deep venous oozing, but the nerve had evidently not been badly crushed. I never speak to the patient during the earlier part of the operation, but while the lower pole is being freed from its connexions and the inferior vessels divided, my practice is first to apply forceps, then to ask some question, and on the first sound of voice to cut above the forceps with scissors. While there is phonation I know that the nerve is not grasped in the forceps.

Another reason against general anaesthesia is that it is usually followed by some vomiting or retching, which is not only extremely painful with a deep and extensive wound in the neck, but also not free from danger, through the possibility of secondary haemorrhage from the large and brittle vessels which have been ligated. With local anaesthesia there is no vomiting.

Should there be any tendency to acute thyroidism, the treatment is to saturate the patient with fluid, preferably by copious ingestion of water. This is impossible immediately after general anaesthesia. Although the cases now never suffer from acute thyroidism, I always insist on their drinking three pints of water within the first two or three hours after operation as a prophylactic. The large size of a goitre is no bar to its removal under local anaesthesia. From one patient I removed a goitre (not exophthalmic, which weighed 1½ lb., and that only represented one lobe and the isthmus. It spread widely under the sternomastoid muscles, displaced the carotid arteries and jugular veins, distorted the trachea, and extended apparently to the base of the skull. I have injected three cases, one after the other, before beginning to operate, and then operated on the three in succession without trouble.

The total number of partial thyroidectomy operations I have performed under local anaesthesia is 113. It was necessary to give a general anaesthetic only to one of them, a girl of 17 years, who was so frightened that the operation could not be commenced until general anaesthesia was used. The anaesthesia is usually exceedingly good, though a little dragging sensation is felt while the deep connexions of the gland are being divided. This part of the operation takes very few minutes.

Even should it be admitted that general anaesthesia might be used in selected cases, the majority are too far advanced for a general anaesthetic when they are sent, or come themselves, to a surgeon, and there are many—all of those constituting the second class mentioned above—to whom it would be courting disaster to administer a general anaesthetic.

How much Gland should be Removed?

The next question is, "How much gland substance should be removed?" The answer is, "Enough to cure the patient." Heineck writes:

The surgeons that have, for the cure of this disease, removed the largest quantity of thyroid tissue short of its entirety, are those that obtained the very best results, both from the standpoint of the number of recoveries as well as from the standpoint of the completeness of recoveries.

Yet for several reasons too much should not be removed at one operation. First, it is bad surgery to remove more than is necessary to effect a cure. More can always be removed, but if too much be removed it cannot be replaced. Moreover, the second operation is safer even than the first, and the patients are so much improved as a result of the first that they face a second with equanimity.

There are differences of opinion as to whether it is necessary to remove more than one lobe. Kocher says that removal of one lobe and ligation of one artery of the other side is sufficient; C. H. Mayo does not advise removal of more than one lobe and the isthmus; Hartley removes considerably more. It is possible, however, that I have not seen their latest publications. In most cases the lobes are so large that if one lobe and the isthmus be removed the remaining lobe is still very much larger than the whole of a normal gland; and it is, moreover, excessively vascular and active. In a case like this the removal of one lobe improves the condition much, but the gland tissue remaining is still sufficient to poison the individual, causing some tremors and palpitation on exertion, and the pulse-rate may still be high.

If the patient is to be completely cured part of the second lobe must be removed. There is no danger of myxoedema if the upper and posterior portion of one lobe be left with its blood supply intact. The removal of portion of the second lobe has cured the condition in every typical case. Some months should be allowed to elapse between the first and second operations, because in many cases palpitation after the operation is simply the result of weakness, and disappears with the returning strength of the patient.

Crushing Gland Substance.

Next to the question as to whether these cases should be treated surgically, the chief interest centres around several points in the technique, chief of which is the method of division of gland substance. Almost all authorities state that the gland should be crushed before division, and that the crushed portion should be ligated or sutured. This is recommended presumably for two reasons, first, to prevent

haemorrhage, and secondly to prevent the exit of thyrotoxic secretion. I regard any crushing as quite unnecessary and exceedingly dangerous.

If the operation is for the removal of one lobe alone, it does not matter much whether the isthmus be crushed or not, though even in this case it is unnecessary. There is nearly always a division more or less fibrous somewhere through the isthmus. This is easily found, and if the isthmus is divided along it there is very little bleeding. Crushing across the isthmus causes an increase in the pulse-rate for some days after operation. Stitching up or tying up the crushed isthmus appears to me to be wrong, because it shuts up the crushed and bruised gland in a closed bag, the only exit from which is through the lymphatics and venules of the gland. It should be treated as an abscess or as an accumulation of any toxic material would be treated—that is, by allowing means of free exit for a day or two by means of a tube. This is shown much more definitely in the removal of half the second lobe. In my earlier operations on the second lobe I used to crush across and attempt to ligate, because the literature had taught me to fear haemorrhage when cutting across the middle of a gland in exophthalmic goitre. If a lobe is crushed across I have always found the patients exceedingly ill and in the gravest danger for some days subsequent to operation from acute thyroidism. I know now that this is due to so much gland tissue being bruised and crushed and enclosed until it is licked up by the veins and lymphatics of the gland and capsule during the succeeding days.

In the whole series of 88 operations for the thyrotoxic variety of goitre I have had only one death following operation, and it was, I believe, due to this cause. The case was my thirteenth. I had just begun to recognize that in a large bilateral vascular goitre the removal of one lobe was not enough to cure the case. The disease being a thyrotoxicosis, the larger vascular lobe which remains is still larger than a normal thyroid, and pours out thyrotoxic material sufficient to cause all the symptoms of exophthalmic goitre. I therefore did two things which I have since seen to be quite wrong. I removed the right lobe, the isthmus, and half the remaining lobe at the one operation; this was the first error. I crushed the second lobe across before dividing it; this was the second and chief error. This extensive removal of gland tissue at one operation is certainly a mistake if the surgeon is at all slow in completing the operation. With the practice that a great number of cases has given I can now remove one lobe, the isthmus, and half the second lobe in much less time than I took to remove one lobe in my earlier cases, and the handling of the gland is much less.

Many cases since the thirteenth have been incomparably worse before operation, but not one of them has caused me any anxiety. I remove one lobe at a time, and the patient stands it well. Later, if necessary, I remove half the second lobe, and again the patient stands it well, but I never crush. Books speak of bleeding as the great danger of cutting across a lobe, and they speak of crushing as the safeguard against bleeding. If a lobe be crushed across, a large quantity of bruised and pulped thyroid tissue must be left, which is taken up by the blood and lymph streams of the gland itself, and causes the gravest condition by acute thyroidism.

My opinion is not formed from that single case but from the facts that all cases in which I crushed were very ill, and conversely that in a larger number of subsequent cases I have sliced a lateral lobe from upper to lower pole without crushing, and there has never been the slightest danger from acute thyroidism. A tube is inserted for two days down to the raw surface of the gland through a separate incision. The collar incision is accurately sutured. The amount of colourless or slightly blood-stained secretion discharged on to the dressings is sometimes amazing; it continues for four or five days, and is, I think, from the cut surface of the gland and not from the surrounding tissues, because it is not present when a single lobe has been removed, the only cut surface there being through a fibrous division in the isthmus. This discharge is not accompanied by symptoms, a fact that seems to me further evidence that acute thyroidism is not due to absorption of thyrotoxin by surrounding tissues, but that, when present, it is due to absorption from crushed gland by the veins and lymphatics of the gland and capsule

itself. One case is interesting in this respect. A second lobe had been partially excised by clean cutting and without crushing, a large raw surface being left. Gauze drainage had been used. Instead of draining, the gauze had blocked the exit. When I next dressed the case I found the neck distended with secretion. I moved the gauze and the retained secretion poured out. It had been under pressure, but the patient had not been distressed. I believe that avoidance of crushing and free drainage are of the greatest importance.

Crushing is not necessary to stop haemorrhage. A lobe may be cut across with impunity. I do it constantly. When operating on a second lobe I cut from the front of the upper pole downwards and backwards to the back of the lower pole. That removes from half to two-thirds of the lobe, while it leaves the blood supply from the superior thyroid artery intact. Also it preserves the parathyroid glandules of that side from injury, though I cannot believe they possess the importance assigned to them by American surgeons.

The haemorrhage looks alarming at first, but the larger vessels are in the capsule, and are easily picked up. Any big point on the gland surface is under run with catgut, and sponge pressure soon stops the oozing. Twice in the series I have, when removing a gauze drain on the second day after operation, separated a ligature from a vessel. The haemorrhage was sudden and great; the wound had to be opened at once to secure the vessel. Since then I have always used a tube, never gauze. Later, with increased rapidity in operating, I have been removing one lobe, the isthmus, and half the second lobe at one operation, when I have judged that wise. The time taken, and the amount of handling necessary for this, are less than was required for the removal of one lobe in my earlier operations.

What I have written may appear to imply that the operation is easy and safe, but its severity should not be minimized. All handling must be of the gentlest nature, and must be rapid. The vessels are increased in number and size, and they are very brittle. If one gets off the track, the haemorrhage may be appalling and uncontrollable. If the operation is prolonged, the bleeding is bound to be excessive. It is not necessary, however, for any of these accidents to occur.

Finally, I would plead for early operation, as soon as it is seen that medical treatment is not effecting a cure, for with local anaesthesia, rapid operating, no crushing, and free drainage, the operation may be regarded as safely.

Analysis of Cases.

The following is a short analysis of my cases:

Total number of partial thyroidectomy operations under local anaesthesia, 113. Of these:

Malignant goitre	2 cases.
Exophthalmic goitre	88 cases, 1 death.
Parathyroid or adenomatous	23 cases, no death.

The parathyroid cases may be dismissed without comment. Of the exophthalmic cases, 52 were typical cases with classical symptoms; 15 of these 52 had part of the second lobe subsequently removed. Of this class I can say that in every case where the removal of the larger lobe has not effected a cure, the removal of part of the second lobe has done so (always excepting the one case which died). In many of the latter cases one and a half lobes were removed at one operation.

Eight cases with irregular heart beats and pronounced oedema. Of these, 4 had part of the second lobe subsequently removed; 4 had a third operation because the upper pole left after the second operation was unsightly. The original goitre had been of immense size. Every one of these stood the operation well. All are still alive but one. She had made a splendid recovery, and three months later went to her country home, engaged in a round of festivities for a week in a climate with the temperature of over 100° in the shade most of the time, and died very suddenly at the end of it. This case, before operation, had oedema of the legs, body, and arms. There were striae around the elbows like those on the abdomen of a multiparous woman, and the evening before operation fluid was drawn off from both pleural cavities. After the operation she passed immense quantities of urine each day. Every trace of oedema disappeared until the week in which she died. All the others are very much improved.

Two cases, irregular, had intense tachycardia, but no glands enlarged and no exophthalmos. Of these, in 1 case I subsequently removed a small piece of the lower pole of the left lobe. She represents the only failure of the series.

Five cases of secondary exophthalmic goitre. In this class cure is rapid and complete.

Seven of the exophthalmic cases have been in males.

A CONTRIBUTION TO THE SURGERY OF LINGUAL THYROIDS.

By WILLIAM STUART-LOW, F.R.C.S.,

SURGEON TO THE CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL;
LECTURER ON PRACTICAL OTOTOLOGY AT THE
MEDICAL GRADUATES' COLLEGE.

THE persistence and development of thyroid remains in the posterior third of the tongue are the least usual of the aberrations to which the thyroid gland is liable, but its occurrence is sufficiently common, and these remains are sufficiently difficult to eradicate successfully and completely to warrant close attention to any improvement in the accepted methods of treatment.

The development of the thyroid gland explains their occurrence. As early as the fourth week, during the appearance of the buccal and pharyngeal portions of the tongue on the floor of the primitive pharynx, the hypoblast between these two parts proliferates and gives rise to a solid protrusion, and the part thus formed pushes downwards and backwards to the hyoid bone, and becomes the isthmus and part of the lateral lobes of the thyroid. The stem of this bud represents the thyro-glossal duct, and the buccal opening of the duct the foramen caecum. It is in the track of this duct that the remnants of thyroid tissue lie. These developmental remains may occur in any part of this canal, and constitute, when arising in the portion of it extending from the foramen caecum to the hyoid bone, lingual thyroids.

There may be one or a number of detached thyroid masses; and when one such mass is removed the others may take on compensatory action and grow, giving rise to a recrudescence of the tumour after operation. This is the reason for the imperative of radical measures in operating on these structures in the tongue.

The case narrated in this paper well illustrates the obstacles encountered in the removal of this fetal manifestation, and proves that the procedure most usually adopted may be futile, and therefore not always the best to employ.

A question that must ever be before the mind of the operator and carefully taken into account before deciding upon operation on the lingual thyroid is whether the thyroid gland in the neck is sufficiently developed to carry on the thyroid function in the bodily economy, or is the lingual tumour the only thyroid representative present? It is on record that excision of the lingual thyroid has been followed by myxoedema. The neck should, therefore, always be carefully palpated, and the outline, size, and development of the thyroid estimated. Should the gland be apparently absent, or be but small, one should certainly hesitate before deciding to operate. It would only be when the lingual tumour was of considerable size, and causing such marked disturbance as to impair the health, or jeopardize life, that a radical operation should be entertained.

In such circumstances it would be preferable to resect the thyroid tumour in the tongue, thus reducing its bulk, and so, in all probability, the distressing symptoms, and at the same time leaving sufficient gland to carry on the indispensable thyroid functions. This course should be chosen even at the risk of a recurrence of the lingual enlargement.

In searching the literature of this subject I have been unable to find any record of the method here adopted having been used for the eradication of these tumours—namely, by splitting the tongue from tip to base. The methods usually chosen have been either that of the galvano-cautery, or subhyoid pharyngotomy, or a combination of partial excision and the galvano-cautery.

The particular procedure selected is dependent upon the size of the growth. If the tumour be large, operation through the mouth is not likely to be successful, as access would be insufficient, unless the method here advocated were adopted. In these circumstances the operation of subhyoid pharyngotomy is that most favoured by surgeons, but this is by no means an ideal procedure.

It is excellently suited for the removal of growths at the entrance to the larynx, that is, involving the epiglottis, aryepiglottic folds, arytenoid cartilages, and in the region of the sinus pyriformis. But for tumours in the locality of the base of the tongue it has the great disadvantage of

opening a communication between the septic cavity of the mouth and the large neck wound. There is much risk of the wound failing to unite by first intention, and of a fistula resulting, or a disfiguring puckered cicatrix occurring, and in the case of a female patient this would be a serious consideration. The patient has to be most careful to maintain a fixed position of the head for some days, and the recovery is therefore slower and more hazardous, necessitating studious nursing and a longer stay in hospital.

Another disadvantage in subhyoid pharyngotomy that must not be lost sight of is that the extent of the opening is restricted by the imminent risk of dividing the superior laryngeal nerve if the transverse incision be carried any distance beyond the hyoid bone, as this nerve enters the larynx by piercing the lateral part of the thyro-hyoid membrane. Should the nerve be cut, the larynx is rendered insensitive, allowing of the entrance of food and mucus, and the wound discharges into the larynx. There is great likelihood of aspiration pneumonia, as these foreign substances cannot be reflexly coughed up, since the sensitiveness of the larynx to their presence has been destroyed, and one cannot trust, therefore, to the cough reflex to prevent secretions from flowing further down.

The tumours formed by lingual thyroids vary in size from that of a cherry to that of a hen's egg or small Tangerine orange. If the growth is small, incision of the covering mucous membrane and curetting, with the subsequent application of the galvanic or thermocautery, will sometimes suffice to get rid of it and prevent recurrence, but this treatment is less likely to be efficient than excision of the capsule, which consists of the dilated remains of the thyro-lingual duct.

Should the tumour be large, then excision becomes necessary, and the chief difficulty is to gain sufficient access so as to leave none of the gland substance behind. This obstacle is most readily overcome by the method of section of the tongue in the middle line.

The case in which this operation was carried out was that of a female, aged 32 years, a teacher by profession, who came to the clinic at the Central London Throat, Nose, and Ear Hospital complaining of something growing at the base of the tongue, of thickness of the voice, and of constant and uncontrollable desire to swallow. On looking into the mouth a large firm swelling was found occupying the region of the lingual tonsil and projecting above the surface quite visibly. She gave a history of a similar condition having existed eleven years before, when an operation was performed at St. Bartholomew's Hospital, and stated that she was again operated upon at the same hospital nine months ago owing to a recurrence. Both of these attempts at excision had taken place through the mouth, but laryngotomy had not been done on either occasion.

The operation here advocated was performed as follows: Under chloroform anaesthesia laryngotomy was performed, and the pharynx being firmly plugged with a capute sponge, the anaesthetic was administered through the tube.

The tongue, being well protruded from the mouth by means of two deeply inserted stout silk cords, was split from tip to base, and in this way the tumour, which was the size of a small Tangerine orange, was effectively exposed. The growth proved to be solid, and was enveloped in a firm, thick capsule; it occupied nearly all the region of the base of the tongue, the structures being so stretched and attenuated over it that there was considerable danger of the whole tongue coming away during the extrusion of the mass. Part of the capsule, very deeply situated near the hyoid bone in the vicinity of the thyro-lingual duct, had to be excised, but this was first thoroughly curetted and the surface well rubbed with a solution of chloride of zinc, gr. 60 to 53. The tongue was then stitched up from tip to base with interrupted sutures of chromicized catgut, except the last half-inch above and below which were left open for drainage.

Rectal feeding was employed for two days, and a spray of peroxide of hydrogen used for the mouth. She made an uninterrupted recovery, and left the hospital on the sixth day.

The tumour proved to be of thyroid-adenomatous nature.

THE annual meeting of the Medical Defence Union will be held at University College, Bristol, on Thursday next, at 4.30 p.m., when the annual report of the Council and statement of accounts will be presented.

PREPARATIONS are being made for a Health Congress in Leeds from July 17th to 24th, under the joint auspices of the Corporation and University of Leeds, the Royal Sanitary Institute, and the Royal Institute of Public Health. A meeting was held in the Town Hall on May 18th, presided over by the Lord Mayor (Alderman F. J. Kitson), at which committees were appointed to arrange for the reception, entertainment, and general comfort of those who will be attending the congress.

NOTE ON THE REMOVAL OF PORTIONS OF DOUBTFUL TUMOURS FOR DIAGNOSTIC PURPOSES.

By ARCHIBALD LEITCH, M.B.,

PATHOLOGIST TO THE CAIRD CANCER RESEARCH LABORATORY, DUNDEE.

DURING a discussion on mammary carcinoma at the annual meeting of the British Medical Association in 1908, Sir W. Watson Cheyne and other surgeons condemned the practice of removing portions of suspicious tumours of the breast for diagnostic purposes. It was contended that by cutting into cancerous tissue the tumour cells were carried into healthy surroundings and that there was grave risk of transferring them into opened lymphatic vessels from which, apparently by a process of embolism, they might be disseminated; and, at any rate, the condition was considerably aggravated by such a proceeding.

Two assumptions are the basis of this contention, first that the artificial transference of the cells from the malignant tissue to hitherto normal tissue increases their malignancy, and, second, that the deposition of these cells at the open mouths of severed lymphatics places them in a position for more rapid dissemination. There is no experimental evidence in favour of the former, and with regard to the latter there is no *a priori* reason why dissemination along opened lymphatic channels should differ from the same process occurring naturally along closed channels. It may, however, be said that by the procedure under discussion a wider area of lymphatic paths is presented to the growing cancer; and if sufficient time is allowed to elapse between the exploratory operation and the extended operation in the case of the tumour proving malignant, this would constitute a danger. Section of a doubtful tumour *in situ* can often determine the diagnosis, and in the case of cancer the immediate and extensive removal that would be practised would eliminate any such danger. Where such section does not render the condition certain, recourse should be had to laboratory methods that allow of rapid diagnosis, the examination of frozen sections, a proceeding which need not delay the operation for more than a few minutes, and which would not increase the supposed danger. To obviate the risks consequent on removal of a portion of a doubtful tumour it was proposed to remove the whole tumour presumably as if it were a simple tumour. Any wider removal than this, supposing no malignancy was present, would not be good surgery; and in the event of the tumour proving malignant, in which case the removal would be admittedly incomplete, would these risks be eliminated or even decreased? The proposition is very questionable, for in circumsecting a malignant tumour the surgeon would be cutting across lymphatic channels on all sides, some of which might be certain to contain cancer cells; the lymphatic and the implantation areas would be enormously increased. Whatever way be adopted, rapid histological methods of diagnosis are essential.

The method which I have found to give the best results is as follows:

Thin slices of the doubtful tissue, about 1 mm. in thickness, are removed, and placed immediately in acetone and taken to the laboratory.

The slices are transferred to hot water for a few seconds, dipped in gum solution, and placed on the stage of a freezing microtome. The current of carbon dioxide is turned on, and the whole tissue is well frozen in less than one minute. The microtome used is a very handy little apparatus made by Leitz, the knife carrier of which is sufficiently heavy to give a good momentum to the razor.

The sections, as they fly off tangentially, are caught in a basin of water held by an assistant. They are floated on to a glass slide, the excess of water is dried off, and a drop of acetone solution of "krystalviole" is placed on the section. This fixes it to the slide and stains it rapidly. The excess stain is removed with water and acetone and the section is cleared with xylol, and is then in a condition to be examined under the microscope.

Good histological preparations can thus be obtained and may be kept permanently. Allowing two minutes for conveyance of the tissue from the operating theatre to the laboratory, during which time the specimen lies in acetone, I have found that on an average the whole time occupied, from the removal of the tissue till the diagnosis is given to the surgeon, is seven minutes. I have also tried to freeze the tissue as it was obtained and to cut sections without

any sort of fixation or embedding, but it is rather hard on the razor, and staining is interfered with. It occupies less time, and is fairly trustworthy. The method given is, however, much superior.

As has been pointed out, doubtful tissue removed for diagnosis should always, if possible, be examined rapidly. Examples of what seem to me dangerous uses of diagnostic removal of doubtful tissues are found in the gynaecologist's curettings. By the curette, in the case of malignant disease of the uterus, all the favourable conditions for wide implantation of cells are supplied. Malignant cells are embedded in perhaps normal tissue, a large lymphatic area is trepanned upon, and, if embolic dissemination by lymphatics or blood vessels be accepted as a possibility, the risks are much increased. But the greater danger of continuous permeation of lymphatics over an increased area is courted when a few days are allowed to elapse between the curetting and the major operation.

From the pathologist's point of view, diagnosis from uterine scrapings is always difficult and liable to frequent errors. The tissue removed is divorced from its surroundings; its proper relationship is often indeterminate. A negative diagnosis is generally worthless, and in practice is not relied upon: a positive diagnosis is frequently untrustworthy. In the absence of the surroundings several conditions are liable to be mistaken for carcinoma or sarcoma even by the most competent pathologists: inflammatory conditions, sloughing fibroids, hypertrophic and hyperplastic endometritis, adenomyoma, leucidua, and conception products. Short of hysterectomy in doubtful conditions, there are no present methods of procuring portions of the suspected tissue otherwise than by the curette, for the reason that it is impossible, without actually seeing the interior of the uterus, to determine the position of the lesion. This, of course, does not apply to the cervix or endocervix. When scraping is resorted to the methods of diagnosis should be rapid, and as trustworthy results can be obtained by the freezing method above indicated as by any other.

But though the problem is different in many respects, it should not be impossible to apply indirect methods of inspection comparable to those adopted in the examination of hollow viscera such as the bladder, or more or less direct methods, as in the case of the oesophagus or rectum. By these means the disease could be located and a portion removed in the condition most suitable for pathological investigation.

THE INCIDENCE OF MORGAN'S BACILLUS NO. 1 IN THE NORMAL FAECES OF YOUNG CHILDREN.*

BY

J. W. H. EYRE, M.D., and E. P. MINETT, M.D.,
D.P.H. D.P.H.

BACTERIOLOGIST, GUY'S HOSPITAL. ASSISTANT BACTERIOLOGIST,
(From the Bacteriological Laboratories, Guy's Hospital.)

IN this JOURNAL (April 21st, 1906, and July 6th, 1907), Morgan (who was at that time Ernest Hart Memorial Scholar) published the results of a bacteriological examination of the stools of children suffering from epidemic infantile diarrhoea. The examination was confined to the group of non-lactose fermenting bacilli, which includes several well-known pathogenic organisms, such as typhoid and the various forms of dysentery bacilli. As a result of his work, Morgan concluded that in this country epidemic diarrhoea is not occasioned by one of the forms of dysentery bacilli, as was the case in some outbreaks investigated in America; but a particular organism, hitherto undescribed, called by him No. 1, was discovered in the stools of 50 per cent. of the cases. The biological characters, the pathogenicity, and reasons for regarding this organism as a factor in the causation of infantile diarrhoea, were detailed by Morgan in the papers referred to.

The etiological importance of Morgan's organism in epidemic diarrhoea has been further investigated during

the last two summers by Morgan and several members of the staff of the Lister Institute, and during the summer of 1908 a small share of the collective investigation was assigned to the Bacteriological Department of Guy's Hospital—namely, to control the investigation of diarrhoea cases by examining faeces from practically normal children (or children suffering from diseases other than those of the alimentary system), in order to determine whether Morgan's bacillus No. 1 was present, and, if so, in what percentage of the cases. These control cases were examined during the epidemic period of the year.

Material was obtained either from cases attending the out-patient department of the Surrey Dispensary, from healthy children accompanying mothers under treatment, or from healthy children belonging to families in which some other member was being attended by the district nurses instructed by that dispensary. No attempt was made to select children of any particular age period other than the broad one comprised between birth and 13 years, but the cases investigated are comprised in the following classification:

TABLE I.
Cases Investigated from July 24th to September 9th, 1908.

Age Period.	Male.	Female.	Total.
0-1	5	6	11 (1)
1-2	5	4	9 (1)
2-3	1	2	3
3-4	5	9	14 (1)
4-5	1	4	5 (1)
5-6	2	2	4
6-7	0	1	1
7-8	0	1	1
8-9	0	1	1
9-10	0	0	0
10-11	0	1	1
11-12	0	1	1
12-13	1	1	2
Not specified	5	4	7
	23	37	60 (4)

In all 60 cases were examined, 23 males and 37 females. These were scattered, so far as their homes were concerned, over the district bounded by the River Thames, Blackfriars Bridge Road, New Kent Road, Old Kent Road, and Bermondsey New Road, a poor and densely-congested area. The general condition of health in the selected cases was not, as a rule, first-class; but care was taken to avoid actual cases of intestinal disease, as well as children belonging to households in which sporadic or epidemic cases of diarrhoea had occurred. Such children as were themselves patients at the Surrey Dispensary suffered usually from some sequel to an infective fever, as will be seen from the following list, which accounts for 41 of the 60 cases:

Sequelae of Infective Fevers.	
After scarlet fever (nephritis) ...	1
After measles ...	7
After varicella ...	1
After pertussis ...	9
Malnutrition ...	3
Bronchitis ...	7
Chorea ...	2
Convulsions ...	1
Rickets ...	1
Congenital syphilis ...	1
Tuberculous joint ...	1
Chlorosis ...	2

41

The remaining 19 children were, so far as can be ascertained, perfectly normal. The period of time over which the investigations extended was nearly two months, from the fourth week in July, 1908, to the second week in September.

Collection of Faeces.

The apparatus employed for the collection of each sample of faeces consisted of a large-sized specimen jar

* The expenses of this investigation were defrayed by a grant from the Scientific Grants Committee of the Royal Society.

containing a small metal spoon fixed to the cork which closed the mouth of the vial. The apparatus was sterilized in the hot air oven at 180°C. In taking the specimen the spoon was filled with a portion of the freshly-voided material, and replaced in its vial, which was then marked with the serial number.

After consultation with Dr. C. J. Martin and Dr. H. de R. Morgan, the following procedure for the detection of Morgan's bacillus No. 1 was agreed upon:

1. Bile-salt agar containing 1 per cent. mannite, and coloured with neutral red was chosen as the *selective* medium. It was used for the purpose of surface plate cultures—the medium being poured in Petri dishes, allowed to set, and dried for an hour at 43° C. before planting.

2. As soon as possible after collection, usually within an hour, a loopful of the faeces was transferred to the surface of the selective medium by means of a sterile platinum loop. An ordinary L-shaped glass or aluminium spreader was then used to distribute the material uniformly, and two or more further plates of the same medium were inoculated "in series," in order to ensure adequate dilution. This first stage yielded nearly one hundred (?) non-fermenters.

3. After forty-eight hours' incubation at 37° C. such colonies, if any were present, as had failed to ferment the mannite were picked from the plates and planted upon sloped tubes of ordinary nutrient agar; after incubation at 37° C. for twenty-four hours these agar cultures were stored in an incubator at 20° C. until the entire series of cases had been examined.

4. Next these agar cultures containing the presumably "non-fermenters" of mannite were replanted on the selective agar, in order to determine the purity of the cultivations thus obtained. [This step is essential, for, as all who have worked at the bacteriology of faeces are aware, it is quite a usual thing, on plating out the growth from what appears to be one single colony on a plate, to find two or three or sometimes more organisms present. This is probably due to the faecal mucus holding several organisms in close contact, and at the same time so firmly that the ordinary method of spreading the faecal material over the plate fails to separate them.]

5. After incubation for forty-eight hours at 37° C., individual non-fermenting colonies were picked from each set of plates and subcultivated once more on to nutrient agar for twenty-four hours at 37° C. At this stage the (?) non-fermenters were reduced to about 60.

6. Each organism was transplanted from the agar into mannite broth tinted with litmus and incubated for forty-eight hours.

7. Such strains as failed to ferment mannite in the fluid menstruum were again plated, this time on Eyre's nutrose agar (prepared with ox serum) containing lactose, as well as on the selective medium, neutral red-mannite-peptone-salt-

meat-agar, and the plates incubated for forty-eight hours. At this stage the (?) non-fermenters were reduced to six.

8. From each set of plates several colonies representing each strain of non-fermenters were isolated and planted upon gelatine, the reactions upon the various carbohydrate media carefully studied, also the indol-producing capacity of each strain investigated, together with the action of each upon litmus milk. In this final study strains were run in parallel series with a cultivation of Morgan's Bacillus No. 1, obtained for the purpose from the Lister Institute from Dr. Morgan himself. This final stage resulted in the isolation of four strains of Morgan's Bacillus No. 1, a percentage of 6.3. The identity of these with Morgan's bacillus are best shown in tabular form (see Table II).

On referring to the original notes relating to the source of origin these four strains were found to have been derived respectively from the four following cases:

Serial number	13	22	24	32
Date of examination of faeces	July 24th	July 31st	Aug. 5th	Aug. 12th.
Sex of child	Male	Female	Male	Female
Age of child	4 years	1 year 2 months	5 years	3 months
Clinical condition	Malnutrition	Normal	Rickets	Whooping-cough
Place of residence	Sumner's Buildings	Southwark Bridge Road	Barnham Street	Douglas Buildings

Beyond the fact that six other children from Sumner's Buildings were examined, with negative results, the above details call for no comment.

THE EMPLOYMENT OF IODIPIN IN SYPHILIS.

By DOUGLAS FRESHWATER, M.A., M.B.,
B.C.CANTAB., M.R.C.S., L.R.C.P.

ASSISTANT IN THE SKIN DEPARTMENT, ST. GEORGE'S HOSPITAL.

IODIPIN has proved itself of such pronounced value in the treatment of certain syphilitic affections, that I do not think it would be out of place to give a short account of the method of its administration, and the special varieties of the diseases in which it is of value.

In 1897 Winternitz* made some experiments on animals, by feeding them on iodized fats, and after death he found traces of iodine in nearly all their tissues, especially in the bone marrow, liver, and mesenteric fat. From these results he concluded that, by the administration of an iodized fat, iodine may be supplied directly to any diseased tissue, and so develop its specific action. He also found that the iodine in these iodized fats—that is, mesenteric fat, etc.—through oxidation in the blood, combined to form an alkaline iodide, and from this it would appear that iodine so combined would have the same therapeutic action as potassium iodide.

In 1898 an additive compound of iodine and sesame oil, called iodipin, was introduced by Merck. It is prepared by repeated iodization of sesame oil by means of iodine monochloride in alcoholic solution. Iodipin is a light oily liquid, and is prepared in two strengths—10 per cent. and 25 per cent. The specific gravity of the former is 1.025, and of the latter 1.227. Iodipin at low temperatures becomes of a honey-like consistency, but it liquefies and becomes clear again if gently heated on a water bath. If exposed to a bright light it in time becomes brownish-yellow in colour, but this is no bar to its subsequent use, provided it remains clear and transparent; but a blackish tint, as well as flocculence or precipitates, renders it unfit for use. More recently a solid iodipin has been introduced, and is supplied in yellow-coated tablets of 7½ grains each, containing ½ grain of iodine, corresponding to 1 grain of potassium iodide.

Iodipin may be administered by the mouth, or by subcutaneous or intramuscular injection. The last method is that most commonly employed on the Continent. The 10 per cent. iodipin was introduced for internal administration, and the 25 per cent. for subcutaneous or intramuscular injections. The 25 per cent. is now nearly always used in both these methods. Iodipin taken by the mouth is passed

* ± = faintly acid; 0 = no change.

practically unchanged through the stomach into the duodenum; here it is acted on by the bile and pancreatic secretions, and is emulsified (Pillemont), the iodine remaining bound to the fatty acids. The process of absorption is the same as for all fats. In the blood, iodipin circulates as small globules of iodized fat, and is partly acted on by the alkaline salts to give off free iodine, while the greater part goes to form a store of iodized fat in the tissues—for example, bone marrow, liver, etc.

When iodipin is given by the mouth, the iodine may be detected in the urine within half an hour. It may be given in capsules, or as an emulsion with tragacanth, but most patients will take it readily in milk, or hot coffee. The dose is 3ss. to ʒi of the 25 per cent. solution, but much larger doses may be given, up to ʒiv or even more three times a day (Radestock²). I have had no experience with 10 per cent. iodipin, but have given 25 per cent. iodipin in capsules of 2.0 grams (2.0 grams = 9 grains KI) in cases of syphilis, when there was an idiosyncrasy to potassium iodide, with favourable results.

For giving iodipin by intramuscular or subcutaneous injection, a syringe with a capacity of 20 c.cm., and with a large nozzle, is required. The needle must have a large bore and be at least 2½ in. long. A suitable syringe is such a one as has elsewhere been described by me.³ The piston is actuated by a rack and pinion movement, to get over the great force required to introduce the iodipin. Unfortunately, the "all-glass" syringes are not strong enough to withstand the great strain required to give an injection. The syringe will remain sterile if it is suspended in a glass jar, and if it is not quite emptied after an injection. The needle must, of course, be boiled, preferably in a solution of common soda. The injections are usually given in the buttock, the upper and outer quadrant being usually selected, as there are said to be fewer vessels and nerves at this spot.

The skin should be first cleansed with ether and then cubbed well with a swab moistened with a solution of mercury biniodide. The needle is then introduced with a sharp stab, and the syringe is removed, the needle being left *in situ*. A short space of time is allowed to elapse in order that it may be seen if a blood vessel has been entered, which mishap would at once become apparent by the exudation of a few drops of blood from the needle. Should this occur, the needle must be withdrawn and introduced afresh, and so on, until a spot is reached where no blood passes back through the needle. It is dangerous to give an injection if blood exudes from the needle, as a pulmonary embolism might easily occur. The filled syringe, having been warmed over a spirit flame, is fitted on to the needle and gradually emptied. A large amount of force is required to give an injection, unless a syringe with a mechanical contrivance such as I have mentioned is used. The syringe and needle are then withdrawn, the site of the injection is massaged for a few seconds with the finger-tips, and a dressing of gauze and collodion applied; this is essential, and must be carried out with care, as the iodipin tends to flow back. The injection causes practically no pain, and any discomfort is due to the accidental movement of the needle-point, or the stretching of the tissues round about, due to the introduction of so large a quantity of fluid. Occasionally during the operation pain may be felt along the course of the sciatic nerve, but I have never found it sufficiently severe to necessitate the injection being suspended, nor has any patient been so inconvenienced as to prevent him getting about his business. It is, however, well to let him rest for a few minutes. A course of iodipin injections amounts in the aggregate to the introduction of 200 to 300 grams, according to the severity of the case and according to the length of time between this and the next course. Twenty grams may be injected daily, or every other day, according to the requirements of the case. It is well to begin with 10 grams, increasing to 15 grams, and then to 20 grams, as the patient becomes more accustomed to the injections. Larger doses have been given, up to 30 grams, but these cause discomfort and are painful. The injection should be given on a different side each time, an average course of about 250 grams, expressed in terms of potassium iodide, is equivalent to about 1,250 grains of this salt. The 25 per cent. iodipin is provided in bottles of 100 grams each. I therefore give the best part of three bottles, in fifteen injections, once or twice a year according

to the case. I do not think that more than six courses of iodipin should be given to a patient, as there is a good deal of scar formation in the tissues of the buttock, which prevents infiltration through the buttock tissues, and also hinders absorption.

Iodipin is sterile and non-irritating, and unless sepsis be introduced at the time of the injection, through some fault in the technique, abscess formation need not be feared. I have never known an abscess follow an injection, but a hard infiltration is often seen, especially if the needle has not been pushed sufficiently deep into the tissues. There may be some slight discoloration of the skin over the site of the injection, but it passes off in a few days. The buttock, as a whole, may become enlarged, owing probably to the infiltration of the large amounts of iodipin into the subcutaneous tissues. Energetic massage will, however, soon reduce this.

Iodipin, after it has been injected, is very slowly absorbed. Traces may appear in the urine as early as the second day after the injection, but it is not until the sixth to tenth day, usually the latter, that a definite iodine reaction is shown on testing the urine. This reaction is easily obtained by adding an equal quantity of nitric acid to the urine in a test tube, waiting a short time for the two to combine, and then shaking up the contents with a little chloroform. The chloroform takes up the free iodine, as shown by a rose to red colour at the bottom of the tube. After long standing, certain alterations occur in the urine, changing the organic iodine combinations into the inorganic, and consequently the amount of iodine that may be liberated with nitric acid increases the longer the urine stands. From the second to the tenth day the elimination of iodine increases steadily until it reaches a maximum, which, in most cases, is 0.2 gram per litre in the twenty-four hours, and when this is reached it is not exceeded, no matter if twenty-five or fifty injections of 20 grams each are given. This proves that iodipin is deposited as iodine fat (as Winternitz says), wherever fat is present, so forming a sort of iodine reservoir, which is slowly drawn upon, that the iodipin is gradually utilized in the system, and that the quantities injected do not cause sudden changes in the amount excreted. The absorption of iodipin is favoured by bodily exercise, and takes place more readily in muscular and energetic people than in those who are either confined to bed or unable to take any exercise. Gentle massage after giving an injection also favours absorption by displacing the iodipin into the tissues of the buttock.

Iodine is secreted by the urine, saliva, and faeces. The largest absolute quantity is eliminated by the urine, the largest relative quantity by the saliva, and only a very little by the faeces. There is none excreted by the sweat. The period of excretion of iodine depends, to a certain extent, on the amount of the injection. Large doses appear to last longer; but this, I think, due to the larger amount absorbed, and so giving longer appreciable traces of iodine in the urine. The rate of absorption is, I think, the same for large or small doses. Iodine may be detected in the urine from three to six months after a course. This period is often exceeded, and one observer found traces after 402 days.

The excretion is fairly regular at first, but towards the end there is a rapid falling off. With potassium iodide large amounts are excreted over short periods. This explains the more energetic action of potassium iodide as compared to iodipin, and, when prompt action is desired, potassium iodide should be given.

I have never seen a case of intoxication with iodipin, even in those cases in which there is marked idiosyncrasy to potassium iodide. Occasionally there may be a few acne spots on the forehead, but these do not pustulate; nor have I seen a case with coryza. The patient, while undergoing an iodipin course, feels perfectly well, and has none of the depression which so often accompanies a course of iodide. As in some cases there is an increase in weight, it appears to be indicated in thin and badly-nourished cases; another important factor in these cases is that there is no disturbance of digestion from free iodine being set free in the stomach.

In secondary syphilis, it is advisable for patients to undergo a course of iodipin injections, in the hope of a prophylactic action against tertiary syphilis and parasymphilitic lesions, especially in those cases which show few

secondary symptoms, as it has often been noticed that parasyphilitic lesions have generally followed such cases, and it is rational to assume that in these instances the toxins which later on cause these lesions are produced early in the disease.

Cases which do not take mercury well will be found to stand it much better if it be given in conjunction with iodine. If the cases are being treated by injections of mercury, it is better to give the iodine either before or after the course of injections, but both injections may be given during the same period; in these cases, one side of the buttock should be reserved for the mercury salts, and the other for the iodine.

In syphilis of the nose, iodine is often preferable to potassium iodide, except in very acute cases, where there is danger of perforation of the septum or hard palate. The putrid greyish masses seen in the nasal cavity, probably remnants of a gumma, are more speedily thrown off under iodine administration than under a long course of iodide. These patients are, moreover, spared any rhinitis, which is easily produced when giving iodide of potassium.

In syphilis of the central nervous system, where iodine is indicated, and the treatment should extend over a long period, this is obtained by the administration of iodine.

One of the well-known effects of the poison of syphilis is arterial degeneration, and, both in its prevention and treatment, iodine has proved to be of value (Kalmus¹). The continuous circulation of iodine in the blood vessels may be assumed to be a powerful factor in the prevention of such degeneration, or if it has already commenced, in arresting its further progress.

The advantages of iodine may be summed up as follows:

1. It is often necessary to give a long course of iodine to patients who are unwilling to take iodide either from its lowering effects or that they are the subjects of iodism.
2. All the iodine injected is used up and must exert its specific action; an exact dosage is therefore possible.
3. Injections are painless, and there is no fear of sepsis if proper precautions have been taken.
4. Iodine subcutaneously does not produce iodism. Patients who have an idiosyncrasy to potassium iodide can take it quite well.
5. Patients remain much longer under the influence of iodine than when iodine is given in other forms. After a short course of injections the system can be kept for a period of four to six months under the influence of iodine.
6. The body is under a slow, continuous regular action of iodine, which is of prophylactic value.
7. In nearly all cases, after a prolonged course of potassium iodide, there are stomach and bowel troubles. This does not occur with iodine.
8. It has a specific action in tertiary syphilis and arterial degeneration.

The disadvantages to the use of iodine may be briefly summarized as follows:

1. In cases of syphilis, when a rapid therapeutic effect of iodine is required, iodine is of little use, as the absorption of iodine is extremely slow, two to ten days elapsing before the iodine can be definitely demonstrated in the urine, so that in cases in which there is a threatened perforation of the palate, cerebral gumma, etc., potassium iodide should be given. Iodine is not a substitute for potassium iodide when active lesions are in progress, but its value in the conditions I have previously mentioned can hardly be disputed.
2. A further disadvantage is that only a small amount of iodine can be absorbed per diem, about one-third what would be given in the ordinary way by the mouth. This can, however, be turned to account in various ways. For example, in tertiary syphilis, after potassium iodide has been administered somewhat vigorously, a course of iodine injections may be given, and the patient may then be left without medicine for some months, during which time the physician knows that iodine is daily passing through his tissues.

HONORARY ASSISTANT SURGEON TO THE ROYAL VICTORIA HOSPITAL AND
THE BELFAST HOSPITAL FOR SICK CHILDREN.

ENORMOUS prostates have been removed in recent years by the method of Freyer, but I am not aware that one of the dimensions of that now reported has been so dealt with.

The patient was a gentleman aged 73, and was under the care of Dr. Colville of this city.

History.

He had always enjoyed good health. About a year ago he was successfully operated on for cataract. For the past ten years he has had to get up once or twice at night to pass water, but has never suffered severe pain. Nine months ago he had an attack of hæmaturia, which came on spontaneously without the passage of any instrument. At this time he passed a good deal of gravel, but no definite calculus. On rectal examination the prostate was felt to be very much enlarged. The hæmaturia lasted one day, and did not recur till the onset of the present illness. Ten days before I saw him with Dr. Colville he had a somewhat alarming cardiac attack during which his pulse fell from its usual rate of 72 to 40. He became pale and collapsed, and his face assumed a bluish tinge. Both hands were cold and anaemic as far as the wrists, and his feet were similarly affected. The heart sounds, especially the first, were faint and weak. There was no increase in cardiac dullness, and no adventitious sounds could be heard. The pulse, though slow, was of fair tension. Two days before I saw him he had a slight attack of hæmaturia. The next day he had retention, but a soft rubber catheter drew off about a quart of blood-stained urine, and during the rest of the day he passed water naturally. Next morning he had retention again, and on this occasion catheterization failed owing to the instrument getting blocked with clot. I then saw him with Dr. Colville, but failed to relieve him with catheters, and we resorted to suprapubic puncture. At this period prostatectomy was considered, and the opinion of Sir William Whittles was sought to enable us to decide, if possible, whether his heart was fit for the shock of the operation. With some misgivings, it was decided that the operation should proceed.

Operation.

Accordingly, the same afternoon I removed a huge prostate weighing 17 oz. by the suprapubic route. The operation was attended with the greatest difficulty on account of the finger being unable to reach the deeper portion of the gland. I had to put the greater part of my hand into the bladder, and even then I had the greatest difficulty in reaching the furthest limits of the growth. In order to deliver the prostate I was obliged to split it longitudinally and remove it in halves. The operation, a truly laborious one, was completed in fifteen minutes from the commencement of the incision, and was conducted under ethyl chloride administered by Dr. Fielden. I chose this anaesthetic because I am usually able to complete the operation in two or three minutes, but I was not prepared for the size of the prostate in this case.

After-History.

The patient suffered from very severe shock, and was with great difficulty kept alive for some hours after the operation, but he made a good rally, and is now—ten days after—doing well. There was also found in the bladder a pretty specimen of mulberry calculus about the size of a small marble.

The only prostate approaching this in size of which I am aware is one mentioned by Mr. Freyer, which weighed 14½ oz. Mr. Freyer says that this was the largest prostate he had removed, and that the labour involved in its removal was very severe. The operation took fourteen minutes, and his fingers, hands, and arms ached for two or three days after. I can endorse this statement as regards my own case. The muscular exertion was certainly very severe.

There are two points in my case besides the size of the prostate. First, the comparatively comfortable time the patient had had with his urinary organs up to the time of this illness, though the prostate must have been of great size for years; and secondly, the condition of his circulatory system, which in my opinion almost precluded the idea of any operative measures whatever.

REPORT CXIV.

TWO CASES OF JEJUNAL ULCER FOLLOWING GASTRO-JEJUNOSTOMY.

IN ONE OF WHICH GASTRIC ANALYSES WERE MADE BEFORE AND AFTER OPERATION FOR JEJUNAL ULCER.

By HERBERT J. PATERSON, M.B., B.C.CAMB., F.R.C.S.,
ASSISTANT SURGEON, LONDON TEMPERANCE HOSPITAL.

NOTWITHSTANDING all that has been written in recent years on the subject of gastro-jejunostomy, there remains at least one problem in connexion therewith in need of further investigation and elucidation. The fear of the possible occurrence of a jejunal ulcer still casts a shadow, faint, it is true, over the otherwise admirable results which follow this operation when performed in appropriate cases. It is of the utmost importance that all instances of this condition should be published, in order that we may have all the available material from which to draw conclusions as to the etiology of this condition, as to the best methods of preventing it, and of treatment should it occur.

The notes of the following case which has been under my care are of interest, as it is, so far as I can gather, the first case in which an attempt has been made to obtain an accurate analysis of the gastric contents, and of the fluid escaping from a jejunal fistula before and after operation for ulcer of the jejunum.

CASE I.—Anterior Gastro-jejunostomy for Pyloric Stenosis: Per- foration of a Jejunal Ulcer Five Years later: Resection of Affected Portions of Jejunum, and Anterior Gastro-jejunostomy "en Y."

H. I., married, aged 47, was admitted into the London Temperance Hospital on August 21st, 1902, under the care of my colleague, Dr. Soltan Fenwick, suffering from pain after food, vomiting, and loss of flesh.

The patient stated that she had always been healthy until two years previously, when she began to suffer from pain after food, which gradually increased in severity, and she had lost 5 st. in weight. For one year she had suffered from vomiting, usually two or three times weekly, large quantities of undigested food being brought up. On admission the patient was much wasted and weak, and weighed 5 st. 5 lb. instead of 9 st. The stomach was markedly dilated, the lower border reaching a handbreadth below the umbilicus. There was constant visible peristalsis and a marked succussion splash. At the level of the umbilicus close to the outer border of the right rectus muscles there was a hard movable lump rather larger than a walnut. There was a marked free hydrochloric acid reaction in the stomach contents after a test breakfast, and also in the contents of the fasting stomach. Lactic acid was not present. Dr. Fenwick thought that the dilatation of the stomach was due to cicatricial stenosis of the pylorus, and asked me to see the patient with a view to operation. The patient declined to have anything done, and left the hospital on August 27th. On September 6th the patient returned, looking a good deal worse, and stating that she had been vomiting constantly. She had lost over 4 lb. in weight, and now readily consented to operation.

First Operation.

On September 8th I opened the abdomen. The stomach was large and much hypertrophied. In the region of the pylorus was a densely hard mass, about the size of a walnut, and situated mainly in the posterior wall. There were no adhesions and the lump was freely movable. Anterior gastro-jejunostomy was performed by means of a single layer of Halsted sutures, the opening made measuring 2 in. The pylorus was explored from within, and a dense, almost complete, stricture was found. The patient made an uninterrupted recovery, and left the hospital three weeks later. This was one of my earlier gastro-jejunostomies, and I must admit at the operation I thought the pyloric lump to be malignant, and I proposed to reopen the abdomen, remove a portion of the lump for microscopical examination, and if, as I anticipated would be the case, the lump were malignant, perform partial gastrectomy. Clearly I was wrong in my opinion, but fortunately the patient felt so well that she declined to have any further operation.

Part of a paper read before the Surgical Section of the Royal Society of Medicine on May 11th, 1909. The expenses of the investigations referred to in the course of the paper were defrayed by a grant from the Science Committee of the British Medical Association.

After-History.

Two years later—in August, 1904—I saw the patient again. She then told me that she had never had a day's illness or pain of any kind, and that she was able to eat ordinary food. She looked a different being, and weighed 9 st. 4 lb., a gain of over 3 st. The abdominal wound was soundly healed, and no trace of the pyloric lump could be felt.

On August 15th, 1907, the patient was readmitted into the hospital. She stated that ever since the operation she had enjoyed excellent health. Two years before readmission she began to have some pain after food, but the pain was not severe and did not cause her much inconvenience. During the previous nine months the pain had increased, nevertheless she continued to eat all kinds of food—cheese, tinned foods, etc. For three months she had noticed a lump forming in the abdominal wall above the umbilicus. On August 15th the skin over the lump gave way, and much yellowish fluid escaped. She was seen by Dr. Percy Edmunds, who at once sent her into the hospital.

The patient looked exceedingly well, and had become very stout, and weighed over 12 st. Midway between the umbilicus and the ensiform cartilage, immediately to the left of the middle line, was an aperture in the abdominal wall, with shelving indurated edges, from which escaped a turbid yellowish fluid apparently containing bile. Around the aperture there was considerable induration, and the skin for some distance around was much thickened. A diagnosis of perforated jejunal ulcer was made. As the patient was so well nourished, I thought that it would be advisable to postpone operation with a view to getting the skin into a more healthy condition, and also to reducing the gastric acidity, and rendering the intestinal contents sterile by keeping her on an exclusively milk diet. This period of waiting was utilized by a series of examinations of the gastric contents, and of the fluid escaping from the fistula. The examinations were as follows:

August 20th. Test breakfast. One hour later stomach contents drawn off, 110 c.cm.

Total acidity, 85.	...
Total chlorides	0.433
Free HCl	0.072
Protein HCl	0.208
Mineral HCl	0.153

During the digestion of the test breakfast and for half an hour later the fluid escaping from the fistula was collected and analysed, with the following result:

Total chlorides	0.405
Free HCl	0.044
Protein HCl	0.175
Mineral HCl	0.186

On August 27th, after patient had been on a milk diet for a week, the analysis of the gastric contents was as follows:

Total acidity, 80.	...
Gmelin's reaction absent.	...
Total chlorides	0.361
Free HCl	0.018
Protein HCl	0.187
Mineral HCl	0.146

At the same time 60 c.cm. of fluid was collected from the fistula.

Gmelin's reaction present.	...
Total chlorides	0.372
Free HCl	0.004
Protein HCl	0.092
Mineral HCl	0.276

September 3rd 70 c.cm. fluid collected from fistula.

Total acidity 60.	...
Total chlorides	0.401
Free HCl	0.004
Protein HCl	0.109
Mineral HCl	0.292

Second Operation.

On September 5th, 1907, an oval incision was made through the skin around the fistula, and carried downwards through the fasciae and muscles. The peritoneum was cut through in the middle line well below the fistula, and a finger introduced into the peritoneal cavity. The jejunum was found adherent to the abdominal wall for some distance on either side of the fistula. The fistula was plugged with gauze, and the peritoneum carefully cut through clear of the area adherent to the jejunum. It then appeared that the fistula led directly into the efferent limb of the jejunum 1 in. below the site of the anastomosis with the stomach; 6 in. of jejunum, including the perforated ulcer and the skin attached to it, were resected. After separating the jejunum from the stomach, the opening in the stomach measured 1 in. by ½ in. This opening was enlarged, and the distal end of the jejunum implanted into it; the proximal end of the jejunum was implanted into the side of the jejunum 4 in. below the anastomosis with the stomach. Both anastomoses were performed by means of two continuous sutures. Great difficulty was experienced in suturing the abdominal wound, as after removal of the fistula and dense hard tissue around it there was a considerable interval between the edges of the wound. It is interesting to note that all trace of the pyloric lump felt at the first operation had disappeared.

After-History.

The patient made an uninterrupted recovery, and on October 12th, after a test meal, 150 c.cm. of gastric contents were drawn off and analysed.

Total acidity, 59.	...
Gmelin's reaction absent.	...
Total chlorides	0.302
Free HCl	0.007
Protein HCl	0.164
Mineral HCl	0.138

She left the hospital in excellent health on October 12th, weighing 9st. 13lb.

I did not see the patient again until August 26th, 1908. She then told me that she had remained quite well until a month previously, when she began again to suffer from pain in the epigastrium bearing no relation to food. On passing a tube in the early morning the stomach was found empty. After a test meal 40 c.m. of gastric contents were drawn off, containing a good deal of mucus and some blood.

Total chlorides	0.430
Free HCl	0.032
Protein HCl	0.317
Mineral HCl	0.080
No lactic acid.	

In view of the recurrence of hyperacidity and the presence of blood in the stomach I feared the recurrence of ulceration. When the patient left the hospital I had advised her never to take meat again, a warning which she had disregarded. I again cautioned her as to her diet, and prescribed bismuth and alkalis. The patient so strongly objected to the use of the stomach tube, and was so alarmed at the sight of blood in the gastric contents that she discontinued attendance for some months, so I lost sight of her again, although I heard indirectly that she was better.

In February, 1909, I saw her again. She was then much better although occasionally she suffered from attacks of pain, usually coming on during the night, accompanied by an acid taste in the mouth, and not bearing any relation to food. Her weight was 10st. 12lb. There was no tenderness of the abdomen, the abdominal scar remained soundly healed, and the patient looked in excellent health. On bismuth and hydrocyanic acid she quickly lost her pain, and I believe that if only she would be more careful in her diet, she would remain well.

In a few of the recorded cases the total acidity of the gastric contents was estimated before operation, and in still fewer the amount of free hydrochloric acid, as estimated by Toper's method, is noted. The estimation of free HCl by this method, however, is very inaccurate, and the amount of total acidity includes both organic and inorganic acids. The important point, it appears to me, is the amount of free hydrochloric acid present in the gastric contents, and this is well illustrated in the case just related. On admission into the hospital for the second time, the free HCl in the gastric contents was 0.072 per cent., more than three times the normal amount. The percentage of free HCl in the fluid escaping from the jejunal fistula—that is, in the jejunal contents—was 0.044, or more than double the amount normally present in the stomach. This observation appears to me of considerable significance with regard to the etiology of jejunal ulcer. Here we had evidence of the presence of a fluid rich in free HCl in a portion of intestine normally unused to the presence of acid contents. That under such circumstances ulceration should ensue is not surprising. The analysis of the gastric contents after a week on milk diet showed a very different state of affairs. The percentage of free HCl was then only 0.018, or just about normal, and the percentage of free HCl in the jejunal contents had diminished from 0.044 to 0.004. From these analyses we may, I think, draw the following inferences:

1. That the presence of an ulcer in the jejunum was connected with the large percentage of free hydrochloric acid present in the jejunal contents.
2. That as the high percentage of free hydrochloric acid in the gastric contents rapidly diminished to a normal amount on a milk diet, the excess of free hydrochloric acid in this case was probably due to errors in diet.
3. That the bile and pancreatic juices in the jejunum usually neutralize the free hydrochloric acid which escapes from the stomach. When, however, free hydrochloric acid reaches the jejunum in great excess, the alkaline juices are insufficient to neutralize all the free hydrochloric acid present.

Incidentally I may point out that although after a week on a milk diet the amount of free HCl had diminished by nearly two-thirds, the total acidity had diminished only from 85 to 80. This illustrates how little information Toper's method gives us as to the amount of inorganic acids present in the gastric contents.

ASE II.—Anterior Gastro-jejunostomy (May, 1899) for Pyloric Stenosis supposed to be Malignant: Recurrence of Pain Five Years later: Seven Years later Separation of Adhesions round Jejunum: Good Health until March, 1908: Death in September, 1908.

Anterior gastro-jejunostomy by means of a Murphy's button was performed by the late Mr. Walsbam in May, 1899, on a man aged 69 years suffering from pyloric stenosis, which was thought to be malignant. He remained well for nearly five years, but

then began to suffer constant pain after food. He was sent to see me by Dr. Howard Distin, who thought that the pain was due to the irritation of the Murphy button, which, so far as was known, had never been passed. The patient's weight was 8st. 6lb., a gain of 3st. since the operation. The stomach was somewhat dilated, and just above the level of the umbilicus there was a rounded induration in the left rectus muscle.

Under medical treatment the patient improved and remained well until the beginning of 1906, when he began to suffer severe pain in the left side, with occasional attacks of vomiting. I saw him again in July. He looked thinner and more careworn than when I last saw him, and he had lost 2st. 4lb. In the left rectus muscle was a tender nodular swelling about the size of a small Tangerine orange. A test meal showed the presence of free hydrochloric acid, a trace of lactic acid. An x-ray photograph did not show the presence of a button in the stomach.

Operation.

On July 20th I reopened the abdomen. There were adhesions at the pyloric end of the stomach. The pylorus was markedly stenosed, but all trace of the former tumour had disappeared. The anastomosed loop of jejunum was firmly fixed to the anterior abdominal wall for a distance of 2 in. There was considerable induration of the jejunal wall as if there existed, or had existed, an ulcer of the jejunum which had resulted in the adhesion of the jejunum to the abdominal wall. The separation of these adhesions would have involved an extensive operation, which I did not think justifiable in view of the patient's age. The other adhesions were divided, and the abdominal wound sewn up.

After-History.

The patient remained well until March, 1908, when his appetite began to fail. He suffered no pain, but he vomited occasionally. I saw him again in July. The stomach was then considerably dilated, and there was marked stomach splash. It was evident that the stomach was not emptying itself properly. With occasional lavage he improved for a time, but later his strength gradually failed, and he died in September, 1908.

Through the courtesy of Dr. Distin I was able to examine the abdominal viscera. On opening the abdomen an interesting state of things was found. The stomach was enormously dilated and flabby. High up towards the cardiac end the button could be plainly felt loose in the cavity of the stomach. The anterior wall of the stomach had been drawn downwards and backwards, so that the site of the anastomosis was posterior rather than anterior. Although an anterior operation with a long loop had been performed, the length of the afferent limb from the ligament of Treitz to the junction with the stomach now measured 4 in. only, and it emerged from under the colon near the splenic flexure. Until a careful examination had been made it was difficult to believe that an anterior and not a posterior operation had been performed. The stomach was distended with formalin and examined at a later date. When the stomach was opened I found that the anastomotic opening was much contracted and admitted only the tip of the little finger, and was surrounded with a considerable amount of indurated tissue. In the jejunum just below the anastomosis the mucous membrane was puckered as if the site of an old ulcer, and microscopical examination showed old chronic inflammation. The pylorus was indurated and almost completely stenosed, so that its lumen was diminished to the size of a cedar pencil.

This case bears out a view I expressed some years ago—that, after the anterior operation, the afferent limb, although at the time of operation it is drawn up round the colon, becomes later displaced outwards so that it emerges from under the colon at or near the splenic flexure. Nature thus appears to protect the afferent loop from the influence of the excursions of the movable part of the transverse colon.

REPORT CXV.

THE CARBON MONOXIDE METHOD OF DETERMINING THE TOTAL OXYGEN CAPACITY AND THE BLOOD VOLUME IN ANIMALS:

WITH SOME EXPERIMENTS ON ANAEMIA AND TRANSFUSION.

BY

A. E. BOYCOTT, and C. G. DOUGLAS,

M.D., R.CH.ONON. M.B., R.CH.ONON.

[FROM THE PATHOLOGICAL LABORATORY, GUY'S HOSPITAL.]

THE carbonic oxide method of determining the total oxygen capacity and the blood volume described by Haldane and Lorrain Smith¹ has been applied to experiments on rabbits. Using the apparatus previously described by Douglas,² we find that this can be done with a considerable degree of accuracy.

1. In a series of experiments, we have withdrawn from or added to the circulating blood of a rabbit a quantity of

blood of known oxygen capacity, as determined by the haemoglobinometer, with the following results:

C.cm. O ₂ Capacity Before.	C.cm. O ₂ Capacity Removed or Added.	C.cm. O ₂ Capacity After.		
		Calculated.	Found.	Difference.
15.9	- 5.7	10.2	10.0	- 0.2
26.7	- 6.6	20.1	18.6	- 1.5
16.8	- 6.9	9.9	10.4	+ 0.5
21.5	- 5.95	15.55	15.4	- 0.15
13.0	- 4.8	8.2	8.7	+ 0.5
21.3	+ 6.1	27.4	27.8	+ 0.4
22.5	+ 6.5	29.0	28.5	- 0.5
26.0	- 7.05	33.05	32.5	- 0.55

2. In another series we compared the total oxygen capacity as found by this method with that calculated colorimetrically by bleeding the animal to death, washing out the vessels, and subsequently mincing and extracting the tissues (Welcker's method). The results were not

Total Oxygen Capacity.		Difference per Cent.
CO Method.	Welcker's Method.	
21.0	19.4	+ 8
17.8	14.8	+ 20
16.1	14.7	+ 10
24.7	21.3	+ 16
23.3	23.3	± 0
26.05	30.55	- 15
21.0	21.1	- 0.5
		+ 5.5

altogether satisfactory; the CO method appears to give results somewhat too high, but we have not been able to make out the reason.

3. In three animals we studied the sequence of events following a single severe haemorrhage. The chief points

Weight.	Total O ₂ Capacity Before Bleeding.	Amount bled.		Days till Original O ₂ Capacity was Regenerated.	Ultimate O ₂ Capacity Reached.	In Days After Bleeding.
		C.cm. Blood.	C.cm. O ₂ Capacity.			
I. 2,180 ...	16.1	41.5	5.7	27	19.5	53
II. 2,450 ...	15.9	48.0	6.9	19	20.4	55
III. 2,170 ...	13.4	44.5	4.8	27	17.6	49

which arise are: (1) In the days immediately following the haemorrhage the blood volume may be considerably increased over the normal; (2) the percentage oxygen capacity (haemoglobinometer readings) is a very uncertain index of the rate and degree of regeneration; (3) over-regeneration occurs; (4) the rate of regeneration may be quantitatively followed day by day in the intact animal; over the whole period of regeneration it varies from 0.18 to 0.36 c.cm. O₂ capacity (0.13 to 0.27 gram haemoglobin) per day, sometimes being as great as 0.41 c.cm. (0.31 gram) per day.

4. In other three animals we followed the effects of repeated haemorrhage. We did not obtain any permanent dilution of the blood, as was found by Lorrain Smith in human cases of haemorrhagic anaemia.⁸ The chief points of interest are the large amounts of blood which may be removed with impunity and the rapid regeneration which occurs. At some points this reached the high figure of 2.2 c.cm. O₂ capacity (1.65 grams haemoglobin) per day.

Weight.	Total Oxygen Capacity.		Amount bled.		C.cm. Oxygen Capacity Regenerated.	
	Before Bleeding.	After Bleeding.	C.cm. O ₂ Capacity.	In Days.	C.cm. O ₂ Capacity.	C.cm. per Day.
I. 2,420...	16.2	18.5	49.9	47	52.2	0.870
II. 3,010...	18.6	25.0	28.9	23	36.3	0.527
III. 3,575...	26.65	23.5	23.8	6	20.65	0.941

5. Aniline poisoning is not altogether suitable for study by this method since the blood becomes yellow and muddy. We found, however, that the apparent anaemia as judged by the haemoglobinometer is greater than the real loss of haemoglobin owing to a marked increase in the volume of the blood.

Date.	Weight.	Total O ₂ Capacity.	Percentage O ₂ Capacity.	Volume of Blood c.cm.	Treatment.
March 26	3,120	19.5	12.0	163	
" 28	3,250	21.2	10.9	195	
" 30	3,020	20.9	13.2	158	0.2 c.cm. aniline daily from Mar. 30th to April 9th.
April 2	2,970	17.5	12.8	137	
" 4	3,000	19.6	11.2	175	2.0 c.cm. aniline April 6th.
" 8	2,980	12.4	5.7	217	
" 10	2,900	10.1	2.8	350	
" 13	2,820	10.5	3.8	276	
" 16	2,670	13.2	5.1	260	
" 24	2,450	10.6	6.5	163	
March 29	2,680	19.3	11.3	175	

The total O₂ capacity was actually halved, while the haemoglobin readings fell from 65 on the human scale to 15 instead of 32.

6. In a case of marked anaemia associated with suppuration, which arose fortuitously in a rabbit which was in hand, we found a marked instance of chlorotic anaemia associated with some loss of total haemoglobin.

Date.	Weight.	Total O ₂ Capacity c.cm.	Percentage O ₂ Capacity c.cm.	Blood Volume c.cm.	Remarks.
May 14	3,200	23.0	13.0	192	
" 22	3,080	23.2	12.95	179	
June 2	3,070	19.5	9.25	210	
" 4	3,000	18.8	9.6	196	
" 11	2,880	18.9	7.6	248	
" 12	2,850	17.3	6.5	256	Obviously ill.
" 13	2,740	15.3	6.7	228	
" 15	2,820	13.6	4.9	277	
" 18	2,620	13.5	3.05	443	Died June 18-19.

The blood volume here was more than doubled, and the haemoglobin fell to 16, though in proportion to the real loss in total haemoglobin it should not have fallen below 39.

7. In three animals we made a series of observations on the fate of rabbits' citrated blood transfused into rabbits. In this series on the whole the haemoglobinometer gives a fairly accurate measure of the total haemoglobin, though we met with some marked exceptions in detail. The chief points ascertained are (1) an accurate measure of the rate of disappearance of transfused blood; (2) the fact that a second transfusion disappears much more quickly than the first. The details of this are still occupying our attention. We may say here, however, that there are no external signs of haemolysis, and the serum is not haemolytic to rabbits' red cells.

Weight of Animal.	Total O ₂ Capacity before Transfusion.	First Transfusion.			Second Transfusion.			Third Transfusion.		
		Amount Transfused.		Normal reached in Days.	Amount Transfused.		Normal reached in Days.	Amount Transfused.		Normal reached in Days.
		C.cm. Blood.	C.cm. O ₂ Capacity.		C.cm. Blood.	C.cm. O ₂ Capacity.		C.cm. Blood.	C.cm. O ₂ Capacity.	
3,750	21.9	52	6.5	8	61	8.01	4	60	5.4	2
3,600	25.9	56	7.05	16	80	9.2	5	70	9.3	7
2,600	21.8	51	6.1	12	63	6.6	5	—	—	—

8. Incidentally we have obtained a number of measurements of the total oxygen capacity and blood volume in normal rabbits, which may be summarized as follows:

	Body Weight, Grams.	Per-centage Oxygen Capacity	Total Oxygen Capacity	Blood Volume.	Per 100 Grams c.cm. Blood.	Body Weight, c.cm. Oxygen Capacity
Average of 3 males	2,490	14.2	19.5	138	5.51	0.780
Average of 12 females	3,115	13.0	21.7	170	5.44	0.697
Maximum..	4,040	16.8	28.7	337	8.6	0.97
Minimum..	2,090	8.5	12.0	84	3.8	0.53

9. The chief results of immediate practical import are three in number. In the first place, the general accuracy of the Haldane-Lorrain Smith method is fully established. In the second place, we have found several examples (after hæmorrhage, aniline poisoning, spontaneous anaemia) in which the degree of anaemia indicated by the hæmoglobinometer is more profound than the actual deficiency of hæmoglobin existing at the time—cases, in short, in which the pathological condition is, as it is in chlorosis, in part a dilution rather than a defect of blood. Thirdly, it is shown that transfusion, if practised as a therapeutic measure, can only be done once on the same individual with much prospect of benefit; the second and subsequent lots of transfused red corpuscles are disposed of so quickly by the recipient that they cannot be of much use.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF GONORRHOEA BY ALLOSAN.

SANTALOL preparations have been widely used for the treatment of gonorrhoea; indeed, of the liquid esters of this drug there is no lack, but only recently has a santalol preparation in a solid form been put upon the market under the name of "allosan," which is the allophanic ester of santalol, and has the formula $\text{NH}_2 \cdot \text{CO} \cdot \text{NH} \cdot \text{CO} \cdot \text{OC}_2\text{H}_5$. It is a white powder of a mild aromatic odour, tasteless, and non-irritating to the mucous membranes of the mouth and oesophagus; it is split up in the intestine, where it does not produce any irritative effect, the separation of santalol beginning after about two hours. A suitable dose is 15 grains three times daily, although in some cases I have given 20, and even 30, grains thrice daily without any harmful effect. I do not wish to claim that allosan is different in its action to santalol, the medicinal active component of East Indian sandalwood oil. It is not, of course, a substitute for the local treatment of gonorrhoea with or without complications, but it is a valuable adjuvant to local treatment. Its action seems to be to diminish the secretion and relieve the irritation in acute uncomplicated as well as complicated cases (cystitis colli posterior urethritis).

The following are brief notes of some cases in which this drug was used:

Mr. J., aged 20, complained of burning pain on passing water, and inability to sleep owing to painful erections; there was a

thick yellowish discharge and painful enlargement of the right testicle; this condition had lasted for ten days without medical treatment. Allosan 15 grains was prescribed in powder three times daily, while locally the orchitis was treated with belladonna and glycerine. In ten days the discharge was practically gone, only a thin, watery, scanty discharge occurring early in the morning; after another four days' treatment the discharge had entirely disappeared and the chordee had ceased. In this case I was satisfied with allosan and glycerine of belladonna, and no injections were given. The patient returned in three weeks and reported that he was quite free from any further symptoms or signs.

Mr. S., aged 28, complained of severe scalding during micturition; a thick discharge had been present for a fortnight; he had been under medical treatment without appreciable relief. Allosan 30 grains was ordered as powder four times daily. In four days the discharge was much thinner, he passed water with considerably less pain, and slept better. The treatment was continued for another five days, when the discharge was watery and scalding pain during urination had nearly gone. The treatment with allosan was continued for another ten days, with injections of protargol 2 per cent., and at the end of this time the patient was quite well.

I have selected these two cases as typical examples of gonorrhoea. I have now treated about 30 cases of gonorrhoeal infection in man with allosan, and the result has been uniformly successful. In the majority of cases towards the end I have, of course, used injections; but that does not diminish the value of the good results obtained by the allosan treatment in the early stage of the infection.

LACTIC ACID BACILLI IN THE TREATMENT OF MELANCHOLIA.

FORD ROBERTSON, whose recent brilliant researches in association with McCrae in regard to the etiology of general paralysis of the insane have created so much discussion, assigns to toxæmic states a large value in the causation of melancholia. (As a curious recapitulation of the dogmas concerning "black bile" of olden times may be noted the modern ideas of toxins.) Maudsley, Clouston, and many others have noted the invariable concomitance between disordered conditions of the alimentary canal and melancholic states. The latter, it is true, are frequently looked upon as causes, the former as effects. But, for the sake of argument, let us assume a contrary hypothesis.

Last summer it was stated in the *BRITISH MEDICAL JOURNAL* that the lactic acid bacilli or their product soured milk, or tablets containing the bacilli, had been tried in such conditions as chronic diarrhoea, catarrhal diarrhoea, constipation, etc., and their method of operation was not empirical, but was based on the hostile influence of the lactic acid bacilli on the other organismal denizens of the intestine. The results were gratifying. It occurred to me that, this inimical action having been proved, the lactic bacilli or their products might well have a beneficial effect in melancholia, the reasoning leading to this conclusion being as stated above. In discussing the matter with Dr. David Hunter, of the West Ham Borough Asylum, I found that the same idea had occurred to him.

Having tried the treatment by tablets containing the bacilli and by prepared milk, I have observed such improvement in the cases as to warrant a short note on the subject. In one case in particular the result has been marked—an example of hypochondriacal melancholia exhibiting such typical symptoms as would have marked him inevitably for inclusion in his categories by Burton: "His soul abhorred all meat. Like Job, he cursed his stars. He was weary of the sun, and yet afraid to die;

vivere nolunt et mori nesciunt." He had the jaundiced eye, the sallow complexion, a more than ordinary constipation. At first the bowels were moved with difficulty, and only when strong purgatives were used. He was given soured milk and bacillary tablets; and the result must be described as satisfactory. Now the bowels move easily (though he will not, by the way, admit that this is so), the complexion has cleared in a marked degree, and in the space of three months he has increased his weight by 11 lb. I do not imagine that ordinary aperient treatment would have wrought this change. Mentally he has become brighter, has taken more interest in his surroundings, has read the papers and books provided, and has conversed freely with his neighbours. In other cases I have noticed beneficial results, but not in such marked degree, though, on the other hand, they were not such profoundly melancholic cases as the one I have mentioned. The cases have been too few in number and the treatment has been carried out for too short a time to warrant me in making any generalization, and my sole object is to suggest that this method of treatment may be given a trial by those better qualified than myself to carry it out, and also with more material for observation to their hands.

HUBERT J. NORMAN, M.B., D.P.H. Edin.,
Assistant Medical Officer, Cumberwell House Asylum.

ETHYL CHLORIDE AS AN ADJUVANT TO NITROUS OXIDE WHEN ANAESTHESIA THROUGH THE NOSE IS DIFFICULT.

CASES in which induction of anaesthesia through the nose by nitrous oxide is difficult or impossible are by no means uncommon in dental work. The administrator may either quickly change the nasal for the ordinary apparatus, be content to give the operator a very short anaesthesia and so disappoint the patient, or else he may stop and explain the position to him and administer ethyl chloride or some other anaesthetic by means of an inhaler covering both nose and mouth. In either case he will lose such benefit as it is possible to gain in induction and maintenance of anaesthesia by the amount of nitrous oxide that can pass through the nose.

It is a great advantage at such times to be able straightway to carry over the patient from his half-stupid condition under the small amount of nitrous oxide inhaled to a light or even deep anaesthesia under ethyl chloride without disturbing him by a change of apparatus, and to have a better chance of being able, when he is once well anaesthetized by ethyl chloride, to continue the anaesthesia by nitrous oxide. I have therefore had made a mouth inhaler, the mouthpiece of which is wholly of metal and fashioned to fit closely to the mouth when kept open by a dental prop; to this mouthpiece is attached a very short wire cage fitted with a rubber bag with a capacity equal to that of a Clover's inhaler. It will stand face uppermost—for example, on a table close to hand.

When needed for use, and while the nose-piece is still applied, 2 or 3 c.cm. of ethyl chloride are sprayed by the anaesthetist's left hand into the bag, which is quickly applied to the patient's face, and he is asked to take a few breaths through the mouth. He will usually not notice the change of anaesthetic, and as there is generally some passage of nitrous oxide through the nose, the bag will gradually become filled with a mixture of ethyl chloride and nitrous oxide, which becomes more dilute as the patient goes under, and a very satisfactory form of anaesthesia, lasting from one to two minutes, is quickly reached. Thus the operator is enabled to do a good deal of work. At times it is impossible to prolong the anaesthesia by means of the nitrous oxide sufficiently, and there is then no objection to a fresh dose of ethyl chloride. If necessary the ethyl chloride may be followed by the addition of ether to strips of gauze attached to the wires and projecting into the bag.

I have several times found this method very useful, and it has already once saved me from the necessity of administering ether. Messrs. Barth, 54, Poland Street, London, have carried out my idea of the inhaler very neatly.

W. J. MCCARDIE, M.B., B.C.,
Anaesthetist to the General, Dental, and
Ear and Throat Hospitals.

Birmingham.

A LARGE DOSE OF SULPHONAL.

SINCE sulphonal was first brought to the notice of the profession in 1887 warnings have so frequently been given as to the danger of its administration in anything over 30 grains, that the following case of an extraordinarily large dose is of some interest.

I was called to see a man, about 30 years of age, who was said to have been asleep for twenty-four hours and could not be roused. His mother, an infirm woman, was the only other occupant of the house, and said that her son had gone out the day previously and purchased a bottle of 100 Burroughs, Wellcome and Co.'s 5-grain sulphonal tablets. On returning home he had swallowed two handfuls of them. On arrival I counted 51 tablets remaining in the bottle and assume that he had taken the other 49, or 245 grains. He had previously had some consolidation of the right apex, and owing to this had lost his post, and become very depressed. There is little doubt that he took the tablets with intent to commit suicide.

When I saw him he was lying curled up on his right side. The pulse was 68 and respirations 20. The pupils were normal in size, but did not react to light. The patella tendon reflex was somewhat difficult to elicit. The tongue was foul and there was a patchy erythematous rash. On being roused he turned his head, scowled, buried his head once more in the pillow, and relapsed into somnolence. He remained in this condition for five days, only rousing occasionally to take a little warm milk, and once in the twenty-four hours to pass water into a bottle. There was no incontinence and his bowels were not opened until the sixth day. The urine at no time contained any haematoporphyrin. The pulse and respiration kept good all the time, although the pulse became weaker as the days went on. After remaining in a condition of stupor for 120 hours he gradually regained consciousness, sat up in bed and took some beef tea. There was no marked loss of power in the limbs following his sleep, and in a few days he was about again.

That he came out of his adventure so lightly was probably due to the slow dissolution of the tablets. The stools afterwards contained no signs of them. His condition presented no symptoms to cause any alarm, and the treatment was purely expectant.

ON

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF THE BRITISH EMPIRE.

GRAVESEND HOSPITAL.

(Two cases reported by SYDNEY W. MILNER, M.R.C.S.,
House-Surgeon.)

CASE I.—*Dilated Gall Ducts in a Child.*

J. G., aged 4, was admitted on January 13th last, with jaundice and abdominal swelling. He had been quite well until four months previously, when he had an attack of jaundice, which quickly passed off.

The spleen was greatly enlarged and firm. The liver was also much enlarged, hard, and the surface felt granular. The edge was very sharp, and could easily be grasped. On the right side of the abdomen, and separated from the liver dullness by a band of resonance, was another large dull area extending downwards into the right iliac region, and occupying the right flank. The dullness did not shift with change of position, and fluctuation could be detected. The urine contained bile and albumen. The faeces were clay-coloured.

A fortnight after admission the child had severe pain and rise of temperature. The pain was localized to a spot to the right of the notch for the gall bladder. At this time an aperient produced a stool the first half of which was clay-coloured and the second half blood-stained. Pain did not recur again until a fortnight later, when the temperature rose to 102.4°. At this time it was noticed that a swelling had appeared at the site of the pain over the right lobe of the liver, like the pointing of an abscess, but

without inflammation of the skin. The child was anaesthetized with chloroform, a small quantity producing deep anaesthesia, and the swelling incised, giving exit to about a pint of bile-stained, offensive, serous fluid, which, from the way it escaped, had evidently been under pressure. The acute pain was considerably relieved by the operation. A large quantity of bile-stained, serous, albuminous fluid escaped daily into the dressings. On the seventh and eighth days after operation there was copious haematemesis of dark tarry blood. Death occurred on the ninth day from exhaustion. It was noticed that the size of the abdomen became greatly reduced after death.

Post mortem the skin incision was seen to open into a small abscess-like cavity to the right of the fundus of the gall bladder. The omentum was turned up and was adherent to the under surface of the diaphragm and the upper surface of the liver. The liver was very hard, enlarged, of a dark-greenish hue, with thickening of the capsule. The cut surface showed many bands of fibrous tissue surrounding larger or smaller green pigmented masses of liver tissue. The intestines were adherent on the right side of the abdomen to a whitish, thick-walled, fibrous sac, which extended downwards into the right iliac fossa, and upwards, narrowing as it went, to the under surface of the liver. In separating the adhesions the sac was inadvertently opened, and thick, purplish fluid escaped. The pancreas was dissected out; it was very firm, and the pancreatic tissue of the head of the gland was seen to be spread out upon the surface of the sac of fluid. The liver and sac were next removed together and more carefully examined. The gall bladder was not enlarged, but was white and thickened and empty. The cystic duct, which was also thickened, opened by a pinhole into the large sac, and the latter was found to communicate by dilated branching ducts with the hepatic ducts within the liver substance. Evidently the cyst had not been opened at the operation, but another collection of fluid had been tapped. The duodenum was searched for the opening of the common bile duct, but this was not certainly discovered. The spleen was firm and enlarged.

Microscopically examined, the liver showed multilobular cirrhosis, with bile staining. The fibrous tissue of Glisson's capsule was increased, and there was proliferation of the bile ducts, but no recent inflammatory change. The pancreas contained increased fibrous tissue, but was otherwise normal. A lymph gland showed signs of chronic inflammation. There was no evidence of new growth. During life a diagnosis of cirrhosis of the liver was made, with dilated gall bladder. Undoubtedly this was a case of dilated gall ducts. The questions why the gall bladder escaped dilatation, and whether the pathological process began in the pancreas, arise.

CASE II.—*Sarcoma of Both Kidneys in a Child.*

E. B., a girl aged 4 years 9 months, admitted on February 22nd, 1909, with abdominal swelling, had been well until one month previous, and had had no children's complaint. The father, mother, and remaining children were all healthy.

On admission the child was listless and anaemic. The face, hands, and feet were oedematous. The abdomen was swollen and prominent in the umbilical region, where a distinct swelling could be felt, resonant on percussion. Both kidneys were enlarged, easily palpable, and smooth. The urine was scanty, and showed a thick cloud of albumen on boiling.

The child became gradually worse, and died rather suddenly after drinking milk on March 3rd, 1909.

Post mortem the abdomen contained some free purulent fluid with clots of yellow lymph. The intestines in the umbilical area were matted together by adhesions around a soft white tumour. On attempting to separate them a mass of the swelling easily came away, opening up the lumen of the gut. Both kidneys were greatly enlarged, white and soft. The ureters were not dilated. On section the capsule peeled easily, revealing a smooth, yellowish-white cortical region spotted with dark blood vessels. The kidney substance was replaced almost entirely by the new growth. There were small secondary deposits on the surface of the liver.

Microscopically the growth was a small round-celled sarcoma.

Reports of Societies.

MEDICAL SOCIETY OF LONDON.

Monday, May 17th, 1909.

CHARLES BARRETT LOCKWOOD, F.R.C.S., President,
in the Chair.

The Annual Oration.

DR. H. D. ROLLESTON delivered the annual oration, entitling his address the Classification and Nomenclature of Diseases, with Remarks on Diseases due to Treatment. Definitions, he declared, were a weariness unto the flesh and the framing of them an intellectual exercise which necessarily often resulted in a compromise. In dealing with diseases due to treatment, he pointed out the serious nature of the consequences resulting from the use of the Roentgen rays in certain conditions. The effect of x rays on the skin and other parts of the body provided an example of a group of morbid changes produced by a new method of treatment. The dermatitis was somewhat analogous to sunburn and the occurrence of malignant disease to Kaposi's disease or the appearance of multiple squamous-celled carcinomas in freckles. Considerable interest attached to the production of sterility as a result of exposure to x rays; that result was probably commoner than was known, for the absence of spermatozoa from the semen thus produced was not accompanied by impotence; Brown and Osgood, indeed, found that condition of unsuspected sterility in eighteen persons who had been employed in manipulating x rays for half an hour to four hours three times a week for from two to six years—a very startling result. It had been thought that the active destruction of cells induced in the x ray treatment of leukaemia might do so much damage to the liver as to give rise to cirrhosis. Mosse had reported a case of lymphatic leukaemia cured by x rays in which the patient succumbed a year later to cirrhosis and ascites. Pleurisy with effusion had also been thought to be caused by exposure to x rays. Great interest attached to the pathological effects of horse serum, either when normal or when containing specific antibodies as in antidiphtheritic serum. The symptoms of the "serum disease" were usually trivial, and even though in exceptional cases they were severe, about nineteen deaths being on record, the benefits of serum therapy were so universal that the infinitesimal risks must be neglected. Recently it had been shown that the entrance of an alien serum into the blood gradually produced a condition of hypersensitiveness to a further dose of the serum. The condition of anaphylaxis, which was exactly the opposite of immunity, had been extensively investigated in the guinea-pig, and it had been shown that in guinea pigs death, with widespread degeneration of the capillary endothelium and haemorrhages, might be brought about by a second injection of horse serum given after a certain interval. The guinea-pigs took about ten days for that hypersensitiveness to develop, but in human beings it appeared to take longer. Thus, if the interval between the two injections was from three to six weeks, there was an "immediate reaction," the symptoms of serum disease appearing within a few minutes to twenty-four hours instead of from seven to twelve days, as after a single injection. If the interval between the two injections was longer—three months or so, there was an "accelerated reaction," which appeared in five or six days. From the large amount of material under their observation Currie and Goodall had collected a considerable number of those reactions, but, fortunately, it did not appear that the results in man were likely to prove fatal, or that they were so severe as in experimental guinea-pigs. The importance of anaphylaxis or hypersensitiveness was far-reaching, for it occurred in connexion with injection of vaccines, and was thus the important factor underlying the positive reaction in the various tuberculin tests. In addition, the peculiar symptoms produced in some persons by eggs, and usually ascribed to idiosyncrasy, were probably examples of anaphylaxis, and it had been suggested that some cases of puerperal eclampsia were of that nature, and due to the absorption of the products of autolysis of the placenta.

LEEDS AND WEST RIDING MEDICO-
CHIRURGICAL SOCIETY.

Friday, May 7th, 1909.

Dr. W. H. CHEETHAM in the Chair.

Cæsarean Section.

Dr. HELLIER read a paper on two cases in which Cæsarean hysterectomy was performed for myoma uteri complicating pregnancy.

In Case I a lady of 35 had a myoma which obstructed the cervix. This had been watched throughout the pregnancy, but at term it was clear that the head could not enter the pelvis, and there were other nodules in the fundus. On January 22nd, 1909, a vigorous male child was removed by hysterectomy, and supravaginal amputation of the uterus followed, one ovary being left. The mother made an excellent recovery and suckled her own child. In Case II, a lady, aged 31, 1-para, had about twenty myomatous nodules in the uterus with obstruction of the cervix. She was operated on in almost exactly the same way as the previous case and made an excellent recovery. The child was a girl, weighing 5½ lb. The mother was not able to suckle it, but it had been reared after some difficulty.

The author considered that most cases of pregnancy complicated by myoma required no operation before delivery. When, however, the parturient canal was seriously obstructed operation was indicated in the interests of both mother and child. Great success attended Cæsarean section under the best modern conditions.

Rupture of Abdominal Wall.

Mr. BASIL HALL described the case of a man, aged 27 years, found lying in the road nearly an hour after a motor accident.

Shock was marked and several coils of small intestines were inside the trousers. There was a large ragged wound on the abdominal wall through which the gut had escaped. The viscera were partly replaced and covered over, and the patient conveyed to his home about a mile away. On examination the intestines were found to be intact, but in one loop the mesentery was cleanly split throughout its entire breadth from its root to the intestinal margin. There was a considerable retroperitoneal hæmatoma below the left kidney; the peritoneum was torn and the left kidney lifted forwards out of its bed. The descending colon was also lifted for a few inches from the posterior abdominal wall and the quadratus lumborum exposed. The viscera were carefully washed with saline solution and sutured, the various rents were sutured, posterior drainage established, and the abdominal wall repaired.

Idiopathic Mydriasis.

Mr. MICHAEL TEALE showed a woman, aged 19, who three days previously had found her left pupil widely dilated and her left eye almost blind. No cause known. On examination the sight of this eye was found to be reduced to vague central vision of large objects, peripheral vision being lost. Pupil widely dilated and fixed, there being no reaction to light or convergence. No abnormality of fundus discoverable by the ophthalmoscope. Slight photophobia but no pain. Cross-examination failed to show that a mydriatic had been used either intentionally or accidentally.

OPHTHALMOLOGICAL SOCIETY OF THE
UNITED KINGDOM.

Thursday, May 6th, 1909.

Mr. R. MARCUS GUNN, F.R.C.S., President, in the Chair.

Tubercle of the Choroid.

Dr. G. CARPENTER discussed tubercle of the choroid in connexion with a series of cases.

The first was a child aged 7, which had been getting thinner, and was admitted to hospital with physical signs at the right apex, front and back. There was a history of abdominal pain, but no cause for it could be discovered by palpation. The child then became drowsy and comatose, with great wasting. There were six choroidal tubercles, and flecks of retinal pigment were scattered about them. Three of the tubercles were crossed by retinal vessels.

Another patient was a girl, aged 2 years. She had been ailing six weeks, and had had sickness and headache five days. When admitted she was suffering from meningitis and died on the sixth day. The right fundus was normal, and no tubercles or optic neuritis could be seen, but on the left side there was slight papillitis. Close to the optic papilla was a tubercle of considerable size, and several blood vessels crossed its face. The retinal arteries were small, nothing was noticed about the veins. The surface vessels of the brain were congested. The diagnosis was verified at the autopsy.

The next case was a boy, aged 17 months, who had much the same physical signs as the foregoing. He had meningitis, which was later corroborated by lumbar puncture.

A fourth case was a boy, aged 2, who had had a bad cough five weeks, and when admitted had consolidation at both apices. There was a small amount of papillitis in both eyes. He died twelve days after admission, no changes having occurred in the fundus in the meantime.

Several other cases of the kind were recorded, and the author then discussed the readiness which had been shown to attribute such appearances to syphilis, whatever evidence to the contrary might have existed. He urged early and systematic ophthalmological examinations, which would often render unnecessary spinal punctures or injections of substances to induce reactions. The paper was discussed by the PRESIDENT and by Dr. FREDERICK E. BATTEN, the latter commenting on the comparative infrequency of tubercle of the choroid in tuberculous children, and stating that he was under the impression that spinal puncture afforded a more certain indication than ophthalmoscopic observation.

Radium and Spring Catarrh.

MESSRS. MACKENZIE DAVIDSON and ARNOLD LAWSON recorded a case of spring catarrh in a boy, aged 12, who suffered from chronic photophobia, lachrymation, and slight conjunctival discharge. It persisted for nearly a year, but no exciting cause could be discovered. Both tarsi were covered with dense, hard excrescences, closely aggregated, and separated by deep, narrow fissures. The retro-tarsal tissue was swollen and hypertrophied, and the viscid discharge was spread over the conjunctival surface. The disease was confirmed by examination of the discharge. All ordinary remedies having failed, Mr. Mackenzie Davidson was consulted as to the possibility of treating the case with radium. Such treatment was carried out for a year, each eye being treated eight times. No pain or other immediate effect was produced, but the granulations gradually subsided. After the eighth application he was quite cured, but a interval was allowed to elapse before publishing the case, so as to be sure there was no recurrence for a long time; 39 mg. of radium were used for fifteen minutes at first, and then 44 mg. Mr. Lawson thought few applications with a potent dose of radium were better than many applications with a weaker quantity. Mr. Mackenzie Davidson discussed the case, pointing out the importance of being sure the strength of radium used was what it was said to be, as he had found serious discrepancies. It was also very important to cut off those radium emanations which were not needed in the cure.

Atropine in Refraction Work.

Mr. R. R. CRUISE read a paper on the abuse of atropine in refraction work, based on an examination of 140 eyes in patients under 16 years of age. He concluded that, on the whole, homatropine and cocaine were quite equal, if not superior, to atropine, though in most cases the result after the two mydriatics was identical. Mr. DEVEREUX MARSHALL, in discussing the paper, alluded to Mr. LANG's investigations on the matter; and Mr. ERNEST CLAEKE said it would have been useful to learn what the astigmatism was in the cases.

Mr. MAYOU read a communication on the disappearance of the iris from the pupillary area as a consequence of injury.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Friday, May 14th, 1909.

Sir THOMAS BARLOW, Bart., in the chair.

Radium Treatment.

Dr. N. S. FINZI exhibited two cases of malignant disease.

In the first case the patient, a woman aged 78, noticed about eight years ago that her left breast felt hard. About three years ago she had some pain and consulted her doctor, who removed the breast in April, 1905. About twelve months ago she noticed some hard lumps under the skin, and when seen at the Metropolitan Hospital by Mr. Peter Daniel in November, 1908, she had several masses about the size of walnuts firmly bound down in the centre of the scar and the axilla, and a couple of nodules under the skin at the lower end of the scar. Under x-ray treatment (four full doses to different parts of the scar) great improvement resulted, and the subcutaneous nodules disappeared. The patient, however, did not attend for some

weeks, and the growth again became rapid and much larger than in November. She had two more doses of x rays on February 24th and February 28th, 1909. From March 10th, 5 cg. of radium filtered through a silver tube 0.6 mm. thickness and 1 mm. thickness of india-rubber were applied over the large mass for fifty-three hours, the position of the tube being altered once. On March 12th a dose of forty-one hours was commenced in the axilla. The radium used was the pure bromide, and was contained in a little glass tube within the silver tube. A considerable dermatitis developed in the two places, commencing almost at once, and reaching a maximum in about three weeks. The area of this, however, was quite small, and could be excised if required. The tumour by April 2nd had almost disappeared except for a little thickening between the two places where the application had been made. That proved to be a definite nodule, and a dose of twenty-six hours with filters of 0.6 mm. silver and 1 mm. lead and six hours with 0.6 mm. silver was given, starting on April 29th.

The second patient was admitted to the Metropolitan Hospital in March, 1909, with a growth on the lower lip, 4.5 cm. in size. It had started as a pimple, which gradually became larger and became crusted over, and had been growing for fifteen or sixteen years. The rapidity of the growth had considerably increased for the last eight or ten months. There were enlarged glands under the jaw on both sides, but larger on the left than the right. Five cg. of radium bromide, filtered through 0.6 mm. silver, were applied to the growth for fifteen hours from March 1st, and the same quantity filtered through 0.5 mm. of silver and four layers of lint for twenty-eight hours from April 1st to the glands on the left side of the neck. Eplilation was noticed on the neck about April 29th, and on the left side of the upper lip on May 5th. Considerable improvement resulted both in the growth and the glands. Commencing on May 4th, another application of twenty-four hours was given to the lip, the filter this time being 0.6 mm. silver and 0.5 mm. lead and two layers of lint.

Mr. GODLEE said it was difficult to understand how the radium applied at one small spot acted so satisfactorily. Mr. W. G. SPENCER gave details of a case of epithelioma of the tongue in which the glands of the neck became infected in spite of two months' treatment by radium in Paris. Mr. A. HOWARD PHIZ said that radium spread out on a pad was apt to lose its power, and Mr. PEARCE GOULD thought that there was little evidence of actual healing over of the growth. Dr. SHAW said that from an examination he had made it appeared that the radium, whatever it was doing to the size of the growth, had not caused any difference in the carcinomatous cells. Dr. FINZI, in reply, said that in Paris they claimed to treat precancerous conditions.

Serum Diagnosis of Syphilis.

Dr. ALEXANDER FLEMING gave a demonstration of the serum diagnosis of syphilis by the "complement deviation" method. This differed from Wassermann's original method in the following respects: (1) An alcoholic extract of normal heart muscle is used instead of a saline extract of syphilitic liver. (2) The natural haemolytic power of human serum for sheep's corpuscles is made use of, thus doing away with the necessity for the haemolytic serum of a rabbit immunized against sheep's corpuscles and the guinea-pig's serum (complement). (3) The amount of blood which can be collected in an ordinary blood capsule will furnish an ample supply of serum for the test.

EXHIBITS.

The following were among the other cases exhibited: Mr. WALTER G. SPENCER: A case after reduction of an old subcoracoid dislocation of the right shoulder, complicated by fracture of the upper third of the humerus, by excavating the glenoid cavity through a posterior intermuscular incision. Mr. V. WARREN LOW: A case of pneumococcal cystitis and arthritis successfully treated by vaccine therapy. Mr. SIDNEY BOYD: A case showing Sprengel's deformity of the shoulder and Hirschsprung's disease, with definite rectal obstruction. Dr. F. PARKES WEBER: A woman three years after omentopexy and peritoneal drainage for chronic ascites connected with hepatic cirrhosis. The patient looked and felt well, and could walk long distances without fatigue. There was no ascites or oedema. Dr. DE HAVILLAND HALL and Mr. W. G. SPENCER: A girl, aged $8\frac{1}{2}$ years, on whom splenectomy had been successfully performed for splenic anaemia (?). Mr. ARCHIBALD SMITH: A man, aged 40, with hernia of the right tibialis anticus muscle. Dr. F. J. POYNTON and Mr. W. TROTTER communicated a paper on the operation of cardiolysis, which was illustrated by a case they exhibited.

SECTION OF SURGERY.

Tuesday, May 11th, 1909.

Mr. WARRINGTON HAWARD, President, in the Chair.

AUTO-INOCULATION OF SYPHILIS.

IN a paper on this subject Mr. JONATHAN HUTCHINSON adduced 4 cases to prove the possibility of auto inoculation at periods of from a few days to two months after the earliest recognition of the first chancre. Lambkin's statement that auto-inoculation was impossible later than ten days, was therefore incorrect. In one of the author's cases a second chancre appeared on the index finger, and was accompanied by axillary bubo, two months after a chancre on the prepuce, which was followed by general secondary symptoms and vigorously treated by mercury. Infection through the unabraded mucous membrane, seemed to him quite possible. He also detailed 7 cases of true second attacks of syphilis—chancre, rash, sore throat, etc.—at intervals of from eighteen months to twelve years after the first attack. The possibility of a second attack was only the expression of the efficiency of the treatment of the first; it was, therefore, obvious that reinfection might occur within two years of the primary infection. Two cases of acquired syphilis in the subjects of the congenital malady were brought forward and discussed. Mr. WARRINGTON HAWARD remarked that the most interesting point was the relation of reinfection to treatment; anything calculated to throw light on the relative value of the different systems of treatment was well worthy of further investigation. Dr. McCulloch pointed out that the reactive processes at any site of inoculation, whether by staphylococcus or streptococcus or whatever organism, in tissues already the host of the spirochaete were necessarily very complex, and induration to be expected; was it certain, then, that the lesions described in the first four cases were really new primary chancres? Mr. HUTCHINSON, in reply, said that all his cases presented the most complete clinical picture of the disease.

Jejunal Ulcer.

Mr. H. J. PATERSON read a paper on jejunal and gastro-jejunal ulcer following gastro enterostomy, which appears at page 1231 of this issue. Dr. CHARLES BOLTON said that gastric ulcer was caused either by some "devitalizing" poison or by a poison introduced from without, such as HCl. Besides the causation of ulcer, there was, however, also the question why it did not heal. From his experiments he was able to say that hyperacidity did not delay healing so long as emptying of the stomach was unimpaired. Acute ulcers in guinea-pigs healed in three weeks, but if the exit of the gastric contents were delayed artificially, ulcers might persist for at least seven weeks. Whilst it required a strength of 0.7 per cent. HCl to produce ulceration in the stomach, it was quite possible that a 0.3 per cent. solution would be efficient in the jejunum, which was accustomed to an alkaline contents. Mr. W. G. SPENCER said that if hyperacidity were really the bugbear Mr. Paterson suggested, it would negative the operation altogether. He thought jejunal ulcers were less common now that the no-loop operation was done. In his experience of the anterior operation, which was said by Robson and Moynihan to be followed frequently by jejunal ulcer, there had been no such occurrence; most of his cases were done for cancer, and such of them as he had had an opportunity of seeing *post mortem* did not show any signs of ulceration at the site of junction. He thought primary union of the mucous membrane was obtained. Mr. JONATHAN HUTCHINSON thought that jejunostomy, which apparently had been done in some of the cases tabulated, was very inadvisable as a deliberate procedure. It had been suggested, too, to divert the bile and pancreatic juice into the stomach as a rational means of overcoming hyperacidity, but the danger of persistent vomiting appeared to him an insurmountable objection. Mr. PATERSON, in reply, stated that the operation was only intended as a last resort in relapsing cases. It seemed to him that Moynihan's case of ruptured duodenum had established the feasibility of the procedure without the promotion of vomiting.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At a meeting on May 7th, Dr. WALKER DOWNIE, President, in the chair, Dr. W. R. JACK read notes of a case of *Tuberculosis of the*

bladder treated by vaccine therapy. The patient was a young woman aged 32, a teacher by occupation. Frequency of micturition with scalding pain dated back four years. It came on acutely, and passed off after varying intervals. In May, 1908, the urine was acid, specific gravity 1020, and contained albumen and pus. Tubercle bacilli were readily detected in the sediment. On cystoscopic examination, tuberculous ulceration was found in the trigone of the bladder and in the neighbourhood of both ureters. Dr. J. H. Nicoll removed the right kidney, the pelvis of which was found to contain a uric acid calculus coated with phosphates. Scattered tubercles were found through the cortex. The right ureter was swollen and gelatinous. Convalescence was uninterrupted. The attacks of pain recurred, and in January, 1909, cystoscopic examination proved the ureteral orifices to be normal, but adjacent to the right orifice were one or two small white tubercles and two flat, yellowish ulcerated surfaces, with rounded margins and evidently tuberculous. Her index to the tubercle bacillus was 0.68. On January 22nd 0.0006 mg. of Koch's bacillary emulsion was injected. A few hours of meatal and hypogastric pain followed, and the index fell to 0.60, but rose steadily to 0.88 on the 24th, and 1.08 on the 28th, and 1.10 on the 31st. Frequency greatly diminished and pain disappeared. On February 2nd 0.0001 mg. was injected. The index did not rise beyond 1.06. After the injection of 0.00012 on February 14th, the index fell to 0.81 and rose to 1.34. Some injections of a vaccine grown from a pure culture of *Bacillus coli* found in the pus were also given and effected a marked diminution in the quantity of pus. Examination at this stage failed to discover tubercle bacilli in the urine and the symptoms steadily improved. Dr. WALKER DOWNIE reported (1) a case of *Epithelioma of the naso-pharynx* treated by radium. The symptoms were severe frontal headache and inability to breathe through the nose. Both nares were found filled with pus. The naso-pharynx was almost completely filled with a new growth, a piece of which was removed and was found to be a cellular epithelioma. Operation was refused and radium was tried. A small quantity of bromide of radium was passed into the naso-pharynx through the inferior meatus. It was at first left in for fifteen minutes, but later was left in for an hour each day. After a week he could draw air through the nose, and headache was less severe. After six weeks of this treatment the tumour had entirely disappeared. He returned again, however, with symptoms of intracranial tumour, from which he died. (2) Three cases of primary epithelioma of the uvula. Each tumour was removed with scissors, cutting away a considerable piece of the soft palate round the tumour. One case died ten years after of a malignant tumour in the right posterior triangle of the neck. There was no recurrence in the throat. The second case returned four years after with a scirrhus cancer of the left tonsil with involvement of the cervical glands, which, with the tonsil, were removed. Dr. A. A. GRAY showed stereograms illustrating normal and pathological conditions in the middle and inner ear. Dr. WYLLIE NICOL showed a new form of test tube. The opening was at an angle of about 45° to the length of the tube for the purpose of facilitating dropping in fluids, as strong nitric acid, from a bottle.

UNITED SERVICES MEDICAL SOCIETY.—At a meeting on April 14th, Colonel D. WARDROP, A.M.S., in the chair, Surgeon KENELM DIGBY BELL, R.N., in a paper on physical training and the medical profession, deprecated the current fashion of men specializing in one form of sport. What was wanted was all-round training. If we were to go to war and had to call upon our men for abnormal feats of endurance, it was all-round physique that was wanted, not the man who said he could not pull an oar but could "put the shot" further than any other man in the South of England, or any other similar case of which there were many examples to-day. It was the duty of the medical profession to ensure that some sound method of physical education was everywhere adopted. Its object should be to increase the strength, agility, and power of endurance of boys and men. By "strength" was meant not large muscular development, as it is so commonly understood, but an even balance of

work between every organ and function of the body, striving to produce an all-round man. The lines of the Swedish system of gymnastics should be followed. It secured all-round development of every organ and function of the body. No exercise is applied for developing, the muscular qualities aimed at being suppleness, co-ordination, smart reaction, and agility. This method had obtained a sure footing in England, as elsewhere, but was not receiving all the attention it deserved—partly owing, no doubt, to the freedom with which so-called professional experts were allowed to practise their various methods of physical culture and to advertise these methods as treatment for the cure of all sorts of diseases, so the mention of physical training had come to have an echo of charlatanism attached to it. The failure of the medical profession to show interest in the subject was also in a measure responsible for the same result. The subject was of immense importance, and should be studied by all medical men.

Rebivius.

CRIMINAL RESPONSIBILITY.

DR. OPPENHEIMER, in the preface to his book on *The Criminal Responsibility of Lunatics*, begins by alluding to the feud between medical men and lawyers on questions concerning the criminal liability of lunatics, and affirms that "almost all the writers who have approached the investigation in a conciliatory spirit have sought success by forsaking the claims of their own professional brethren and blindly recognizing the opponents' claims." There is a good deal of truth in this, and we therefore welcome the work of one who is both a medical man and a lawyer, and one in whom also a very extensive knowledge of comparative jurisprudence is combined with eminent analytical acumen. The work differs from many others published in this country, and gains added value by the fact that it is based upon a study of the articles and explanatory "motives" of the penal codes of all countries. This alone would justify its publication, but it is the author's application of these results to English law which make it interesting, if not indispensable, to English students. A remarkable fact—clearly brought out by Dr. Oppenheimer, and of which some, at any rate, of the medical men pressing for alterations in the English law may be unaware—is that in almost every country the same antagonism between law and medicine which obtains in England is to be found, and, further, that the very changes which by many here are urgently called for—for example, the competency of medical experts to deal with questions of responsibility and the exoneration by insanity *per se*—are condemned by medical opinion in those very states where these postulates have been realized in legislation. The French penal code, which identifies insanity with irresponsibility—

Art. 64. There is neither crime nor offence if the accused was in a state of mental alienation at the time of doing the act, or if he was constrained by a force which he could not resist,

—is constantly referred to by the author, and furnishes an interesting example of the way in which an apparently rigid and logical rule can be so stretched as to subvert entirely the ends of justice. By this confusion of insanity and irresponsibility the French law delegates judicial functions to the medical expert, and the reports of the physician usually include with the results of medical diagnosis an opinion as to the responsibility of the accused and a statement as to necessary defensive measures. The question of responsibility is not a medical concept and is not to be found in the French code, and the introduction of this criterion of responsibility and, by implication, of freedom of the will has been brought about, Dr. Oppenheimer says, by a recognition of the fact that the text of Art. 64, if taken in its natural sense, would lead to appalling results.

"Thus the French law, starting with the principle of the absolute irresponsibility of the insane, arrives, by means of

¹ *The Criminal Responsibility of Lunatics. A Study in Comparative Law.* By Heinrich Oppenheimer, M.D. Heidelberg. M.R.C.P. Lond., LL.D. Lond., Barrister-at-Law, etc. London: Sweet and Maxwell, 1909. (Demy 8vo., pp. 283. 10s. 6d.)

judicial interpretation in practice, at the same results as flow directly from the text of Par. 51 of the German code," according to which "there is no punishable act if, at the time of doing it, the actor was in a state of unconsciousness or of morbid disturbance of the mental faculties which excluded the free determination of his will."

Curiously enough, Dr. Oppenheimer says, the free-will test is looked upon in Germany with the deepest distrust.

Thus we arrive at the strange result that, whilst in France interpretation has introduced the will test of which the text of Art. 64 knows nothing, in Germany interpretation has in the case of mental disease eliminated it, though the letter of Par. 51 prescribes it in so many words.

Nevertheless, Dr. Oppenheimer "emphatically concurs in the opinion that freedom of the will is a fundamental postulate of all existing systems of penal law and the only possible justification for the infliction of punishment *stricto sensu*," and dismisses rather summarily the views of the positive school who would once and for all give up the notion, even the very word, of "responsibility," including those, we take it, who would ask instead, "Is the accused a danger to society, and if so, how dangerous?"

Accepting English law on this point as it is and not as it ought to be, Dr. Oppenheimer's discussion and analyses are admirably clear and thorough. It may not, however, be out of place to draw attention to two statements, made in different chapters but relating to the same phenomenon, on which the author may yet alter his views. The first statement refers to those cases in which, though, according to Dr. Maudsley "there have not been any previous symptoms to indicate disease, it is still possible that the crime may mark the period when an insane tendency has passed into actual insanity—when the weak organ has given way under the strain put upon it." Concerning this Dr. Oppenheimer says:

The commission of a crime by a person who has never been suspected to be insane by his friends or relations, may certainly be the occasion which first attracts attention to his mental condition and causes him to be, for the first time, subjected to medical examination; but the alienist will discover independent signs of undoubted lunacy, apart from the criminal act, and that which strikes him as peculiar in the act itself will not be the only material for him to work upon; it will in his hands be merely an index to the discovery of those morbid phenomena which enable him to diagnose an ordinary mania, melancholia, delusional, epileptic, hysterical insanity. But he will not then speak of "mania transitoria."

The second statement occurs in a chapter headed "The Critical Moment."

Considering that insanity generally runs a very protracted course, and that even most of what are called acute attacks last weeks and months, we are, in the absence of cogent proof to the contrary, not merely entitled, but forced to draw the inference that a prisoner shown to have been deprived, by mental disease, of the faculty of discerning between right and wrong on the 1st of March, was probably in the same state of blissful ignorance on the 1st of February, and on that day dedicated to him and to all his fellow-fools.

Briefly and in no contentious spirit it may be said that a little practical experience of criminal lunatics would convince the author of the error of his views on this matter, and that an acute episodic psychosis may occur, in which murder may be perpetrated, on February 1st; the prisoner may convince the experts of his sanity on March 1st, and the true—that is, in all human probability the true—state of affairs only be revealed by subsequent developments, it may be many months later. For this reason, we note with approval that Dr. Oppenheimer endorses the German criminal procedure by which an extended period of mental observation in a lunatic asylum of accused persons suspected of insanity is provided. Also the author's attack on the doctrine of partial insanity and his plea for the formation of a permanent professional body of medical experts attached to courts in an official capacity, analogous to the *Gerichtsarzte* in Germany, will probably meet with general acceptance. Dr. Oppenheimer's work is a valuable contribution to the literature of a most important subject, and will repay careful study.

RENAL DISEASE.

The volume on diseases of the kidney in Brouardel and Gilbert's system of medicine has been written by E. JEANSELME, A. CHAUFFARD, P. E. WEIL, and L. LAEDERICH.²

² *Nouveau Traité de Médecine et de Thérapeutique*. Publié sous la direction de MM. Gilbert et Thoinot. xxi. *Alcaladies des Reins*. Par E. JEANSELME, A. CHAUFFARD, P. E. WEIL, et L. LAEDERICH. Paris: J. B. Baillière et fils. 1909. (Roy. 8vo, pp. 462. Fig. 76. Fr. 9.)

of whom the first two deal with the examination of the urine and the last two with diseases of the kidneys. It seems to be a mistake to say (p. 59), as is said in the chapter on albuminuria, that mucin is coagulated by heat, nor is it altogether satisfactory that Bouchard's views on retractile albuminuria, should be given without a warning that the opinion of the eminent professor is no longer accepted by urologists. There is a want of detail in the description of the reactions given by the various protein substances called albumose, as Bence Jones's albumen (hetero-albumose), for example, reacts differently to ordinary deuto-albumose. The statements respecting benign albuminuria are not clear, and there is no reference to the benignity of albuminuria in boys when unaccompanied by other indications of renal disease. It seems strange to see any doubt cast on the presence of sugar in normal urine although the quantity is too small to be detected by the ordinary methods of examination. Under the description of the acetone bodies it is surprising to be told that the ferric chloride reaction has been abandoned because of the fallacy which arises in people who are taking salicylates and allied drugs; such a fallacy is easily eliminated, and we should have supposed the ferric chloride to be the most usual and at the same time the most useful ordinary test. None of the methods proposed for detecting acetone are approved by the authors, but they omit the method generally favoured in this country of adding a few drops of solution of nitro-prusside of sodium, and following this by excess of strong solution of ammonia. Although the presence of acetone in the urine of starvation is mentioned, nothing is said of the influence of meat diet in producing it. The description of the examination of urine by the use of a separator and catheterization of the ureters does not include the injection of indigo-carmin, which is generally recommended as the best of the colour methods, while in connexion with the influence of diseases of the pancreas on the urine there is no reference to Cammidge's reaction. On the whole, however, the account given of the examination of the urine is clear, and is illustrated by excellent figures printed in the text. The description of diseases of the kidneys occupies the greater part of the book, and is admirably done, but we observe with surprise that there is no separate description of puerperal nephritis or of those cases dependent upon diseases of the pelvic organs; nephritis thus produced differs greatly in its results from others due to the action of constitutional poisons; retinal disease, for example, is rightly spoken of as of grave significance; but in puerperal nephritis it is not, and this exception from the rule should have been given. The attitude of the writers respecting waxy kidney is unsatisfactory, for it ought to be generally known that the description given by Grainger Stuart was based on a misreading of pathological facts; his waxy kidneys were cases of chronic Bright's disease in its various forms complicated by the presence of waxy degeneration. Where waxy disease affects the kidney in common with the liver, spleen, and other organs, there may be no albumen in the urine; it is therefore only as a complication that waxy degeneration appears in the category of Bright's disease. The danger suggested (p. 430) of drinking more water than the kidney can eliminate seems somewhat fanciful, as excess of fluid is easily got rid of; and so long as it does not contain irritating or poisonous constituents it is improbable that the kidney could be damaged. With regard to dropped kidney, the view taken by the authors is that nephropexy is seldom needed, as general experience has proved the unsatisfactory results of surgical interference in local neurasthenic troubles; but that when the attacks of pain are severe and are not relieved by wearing a belt, when there is intermittent hydronephrosis, or where the nervous symptoms are clearly dependent upon the kidney lesion, the performance of the operation may be expected to be followed by good results.

URINARY SURGERY.

THE book by Drs. WATSON and CUNNINGHAM on the surgery of the urinary tract³ may be divided, for the purpose of review, into three parts: the sections on the

³ *Diseases and Surgery of the Genito-urinary System*. By F. I. WATSON, M.D., and J. H. CUNNINGHAM, jun., M.D. Two vols. London: Henry Kimpton; Glasgow: Alexander Stenhouse. (Imp. 8vo, pp. 627 and 474. Engravings 454, 47 coloured plates. 23 3s.)

anatomy of the various parts, those on general surgery and those on the technique of operations. The first of these is not well done. To begin with, it is not accurate; secondly, the same structure is often given a different name in the text and in the picture illustrating it; apart from these defects, such descriptions are out of place in a book of this sort. The anatomical details are dealt with superficially and in less detail than can be found in any textbook. Any one setting out to read such a book, which professes to be an advanced treatise on urinary surgery, knows all the anatomy that it contains, and the descriptions should either be left out altogether or written in such detail that the reader can learn something new, and not have to wade through page after page of elementary work. But if this first section be bad, the second two are good. That on general surgery is an excellent discussion on the urinary tract in all its bearings, while the part on technique gives the operations in a way which does not make easy armchair reading, but which is excellent for following out in the operating theatre or on the cadaver. At the end of the description of each disease is a series of illustrative cases, the majority being interesting and valuable; some, however, seem redundant, notably the lengthy description of a case of congenital occlusion of the urethra in a fetus, which has no practical bearing on the surgery of the part. Many of the coloured plates, too, are unnecessary; they are indeed beautifully executed, but have no very great value from the instructional point of view, and are no doubt a potent factor in making the price of the book so much. We do not mean to say that, as it stands, the authors and publishers are asking an excessive price in proportion to the cost of production, but the number of medical men who can afford to pay three guineas for a book on one single branch of surgery is not very large. Yet we must not quarrel with Dr. Watson on this point, as he tells us in his preface that one of his chief aims has been to produce a book with "as complete and artistic an illustration for the work as the author could secure." To sum up, then, this is an excellent work, showing a close practical knowledge of the subject and much painstaking labour. But we should like it better if, by leaving out all the anatomical descriptions and the coloured plates, it could be presented to us at a considerably cheaper rate.

A book to be a good one must fulfil its purpose as well as be correct and well written. Dr. CABOT, of New York, in his book on *Disorders of the Bladder*,⁴ aims at writing for the general practitioner. There is nothing actually wrong in the book, but we do not think it will fulfil the purpose with which it was written. The first chapter is an antivenereal essay written for the public at large, the second is on anatomy, and tells just so much about the anatomy of the urinary organs as would be remembered by a man who had just scraped through the easiest anatomical examination on record, even if he lived to 80 years of age. The third is on "urinalysis," and tells nothing that is not better told in any textbook of medicine that the practitioner may have on his shelves. Three chapters describe cystoscopy, the first of which is little more than an instrument maker's catalogue. Three short chapters describe the causes of cystitis, and the last describes "senile prostatic hypertrophy." The best chapter is that on contraindications to cystoscopy.

The lectures on the methods of investigation and the diseases of the urinary organs in both sexes, by Dr. L. BURKHARDT and Dr. O. POLANO of Würzburg, are admirably clear and magnificently illustrated. Being intended for students, they are necessarily somewhat elementary, but are quite up to date in the description of the methods of examination and also in the accounts of the various diseases, but in certain parts, as, for example, in the examination of the urine, the attempt to deal with too large a subject in a single lecture is hardly satisfactory. The lecture on stricture of the urethra is a good example

of the authors at their best; they say very justly that as the symptoms are so dependent upon the complications, no two cases are alike; that traumatic strictures develop in, at most, weeks or months after the event, rarely longer, but the injury need not have been severe or attended by any external wound. Asthma is mentioned as an occasional result of stricture, the connexion being shown by its disappearance when the urethral condition is cured. In certain cases they speak favourably of the results of excision; they have no personal experience of electrolysis, and though they mention fibrolysis, they express no opinion as to its value. In early prostatic hypertrophy the importance of warm clothing is urged, and the operation of suprapubic prostatectomy is spoken of favourably, but not as favourably as it deserves; Bottini's excision by galvano-cautery, vasectomy, and other obsolete operations being described in terms of almost equal praise. The description of cystoscopy is good, and is illustrated by life-like coloured plates. The authors do not seem very much impressed with the value of radiography in the diagnosis of urinary diseases. All the modern methods for investigating the functions of the two kidneys by separating the secretions by catheterization of the ureters, the use of separators and the use of indigo-carmin, methylene blue, and phloridzin are given fully. They describe cryoscopy and point out its fallacies, and refer to the examination of the electrical resistance of the urine by Kohlrausch's apparatus, which, though it seems to have been little used, is said to require very little urine, and to be quickly performed. Albarán's method of determining the physiological capacity of each kidney by the estimation of the various urinary excreta, especially urea and sodium chloride, the patient being put on a definite diet, is truly called a lengthy business for both doctor and patient. Movable kidney is said to be present in from 85 to 90 per cent. (!) of the female sex, and is attributed to repeated pregnancies, carrying heavy loads, too vigorous massage in the lumbar region, falls, injuries, and especially to predisposition from the so-called "enteroptotic habitus." They regard it as in itself a harmless lesion which may exist without causing symptoms. With respect to Edebohls's operations for nephritis, they confess that German surgeons have not been able to obtain results as brilliant as those described in America. The last chapter contains clear and well-illustrated descriptions of certain typical operations, and a number of useful prescriptions are printed in an appendix.

The second edition of the American translation of Professor CASPER's excellent and well-known *Textbook of Genito-urinary Diseases*⁵ has been revised and partly rearranged by Dr. BONNEY, who has also made further additions to the text and to the number of illustrations. The section on the treatment of hypertrophy of the prostate has been revised by Professor Casper himself, who is of opinion that when catheterization fails, and when a major operation is not contraindicated, the choice of procedure lies between the Bottini operation and suprapubic prostatectomy. Bottini's operation, however, in Casper's experience, as a rule, is only palliative, and suprapubic prostatectomy offers the best chance for complete cure, though the relatively high mortality militates against its universal employment. That this combination of German and American views and methods concerning genito-urinary surgery has met with favour is evident, for it is barely two years since the first edition was reviewed in these columns.

DISEASES OF THE BREAST.

Diseases of the Breast, by W. L. RODMAN,⁶ is a work by one who has for many years been known to take a keen interest in this department of surgery, and has had no small share in its development. It is a readable book containing definite views clearly expressed, and shows a catholic acquaintance with the actual practice of surgeons in many quarters as well as with their writings. In a

⁴ *Clinical Diagnosis and Treatment of Disorders of the Bladder, with Technique of Cystoscopy*. By Ellen Cabot, M.D. New York: E. B. Treat and Co. 1909. (Demy 8vo, 225 pp., 41 illustrations, 1 coloured plate. 2dols.)

⁵ *Die Untersuchungsmethoden und Erkrankungen der männlichen und weiblichen Harnorgane für Ärzte und Studierende*. In xvii Vorlesungen. Von Dr. L. Burkhardt und Dr. O. Polano. Wiesbaden: J. F. Bergmann; and Glasgow: F. Bauermeister. 1908. (Demy 4to, pp. 381; figs. 105; Tafeln iii. 10s.)

⁶ *A Textbook of Genito-urinary Diseases, including Functional Sexual Disorders in Man*. By Dr. Leopold Casper, Professor in the University of Berlin. Translated and edited with additions by Charles W. Bonney, B.L., M.D. Second edition. London: Rebusman Limited. 1909. (Royal 8vo, pp. 645. Ill. 230. 24 plates. 21s.)

⁷ *Diseases of the Breast, with special reference to Cancer*. By William L. Rodman, M.D., LL.D. London: S. Appleton. 1908. (Roy. 8vo, pp. 398, 111 illustrations. 16s.)

monograph one looks for a full discussion of unsettled problems, a requirement which Dr. Rodman's book fulfils. In the earlier chapters the most interesting and uncertain question discussed is the true significance of the changes usually described as chronic mastitis; Dr. Rodman believes chronic diffuse mastitis with cyst formation and general cystic disease to be one and the same disease, and that an important influence in causation is to be ascribed to interruptions in pregnancy with the consequent sudden arrest of evolutionary changes in the breast. This is a suggestion of importance, and the whole question is in want of further clinical and pathological investigation. In regard to the simple growths Warren's classification is adopted, probably the most satisfactory from the morbid anatomy point of view. The only criticism it seems worth while to make is to express a doubt as to the propriety of describing some of the fibro-adenomata as intracanalicular and others as pericanalicular, with an implied difference in site and tissue of origin, a difference which, in our opinion, cannot be supported.

In regard to carcinoma, the author does well to emphasize the distinct features, both histological and clinical, of adeno-carcinoma. One would have liked to find a more emphatic insistence on the fact that chronic mastitis and papillary cystadenoma are conditions liable to cancerous transformation, and distinctly dangerous for that reason. The theory of visceral dissemination by lymphatic permeation, as put forward by Handley, is not accepted as a whole, and in this matter the author will receive the support of many of those who have worked at the subject. In Handley's work, which is in a sense a restatement of long-accepted observations, the permeation theory is carried to its extreme. The merit of the work is not the discovery of permeation as a new principle, as some writers appear to believe; this principle of extension was discovered almost as soon as the morbid anatomy of cancer began to be studied; its merit lies in pointing out new directions of permeation, and demonstrating how widespread the process may be at early stages. Attempts to make the process cover all thoracic and abdominal metastases fail. Dr. Rodman's discussion of diagnosis is very helpful; in doubtful cases he favours the method of immediate microscopy; he does not appear to attach so much importance to the demonstration of adhesions in the case of doubtful tumours as some other surgeons. His views as to the prognosis of operation are expressed in the following terms: "Surgery should cure one-half of all cases, provided that they can be subjected to the complete operation early in the course of the disease." The illustrations of the operation for carcinoma are very good, as are also the coloured plates throughout the book. It is altogether an excellent work, and deserves a wide popularity.

PLASTIC SURGERY.

ON the Foundation Day of the Emperor William Academy of Military Education in Berlin, Professor HILDEBRAND delivered an address in which he reviewed the history of plastic surgery from the earliest times, its present state, and the prospects of its future development.⁸ The earliest work in which the subject is treated is that of Celsus, who gave clear directions for the repair of defects of the lips, nose, and ears by sliding skin flaps without twisting. From the time of Celsus until the artistic renaissance, there is no record of any advance. Perhaps, as Professor Hildebrand suggests, the newly awakened sense of beauty then caused a demand for the restoration of unsightly defects. However this may be, the first attempts were those of Tagliacozza to restore the nose. The nose has always been considered an important organ, as readers of Sterne will remember. Its loss was thought so much of that the canonists allowed it as a good reason for nullifying a betrothal. To Dieffenbach the credit is due of treating the subject in a scientific spirit, by which alone he said could surgery hope to progress. His results were noteworthy in his own day, but he prophesied greater progress in the future. This progress has been rendered possible by the work of Lister, not only in the treatment

of surgical wounds, but also in the experimental work to which plastic surgery owes so much. The object of a plastic operation should be, not to transplant a substance that will remain as a mere foreign body, but one that will be capable of growth and development in its new surroundings. In respect to this possibility, the tissues differ greatly. The wonderful technical skill of experimenters such as Carrel, of New York, has proved that whole organs, such as the kidney, and even a whole limb, may be transplanted and remain permanently effective. Striking as these results are, the difficulty of obtaining healthy human organs must render their practical value small.

BACTERIOLOGY.

DR. BOLDUAN's translation of Professor DIEUDONNÉ's useful and highly practical treatise on *Bacterial Food Poisoning*⁹ is well worth reading. In addition to a full account of the various types of meat poisoning and the bacteriological identification of the organisms to which it may be attributable, the book contains instructive chapters on poisoning through fish and molluscs, cheese, ice cream, potatoes, and canned goods. The translator has incorporated some additional records of outbreaks of food poisoning, and has also supplemented the author's statements regarding prophylaxis and treatment. The book raises a minor question which is rather perplexing. How can an animal be slaughtered after it is dead? On p. 13 reference is made to a calf "which had been slaughtered either after death or while moribund."

Dr. MINETT's small and very condensed laboratory guide to the *Differential Diagnosis of Bacteria*¹⁰ is a useful collection of memoranda, but seems to have been put together rather hastily. The first twenty-nine pages deal with the identification of bacteria and make constant references to various staining methods. One naturally expects that the descriptions of these methods should come first. On p. 2 we are told that they are described in the appendix, but we find that the appendix begins on p. 42, that the staining methods are described not in that section but on pp. 30 to 41. Throughout the book we think that the desire for condensation had been carried too far. The author seems to be in a hurry; his book contains valuable advice, but it needs a little expansion in order to become palatable to the average student.

DESIGN IN NATURE.

IN the compass of three large volumes entitled *Design in Nature* the late Professor J. BELL PETTIGREW has embodied a long series of beautifully-illustrated essays on anatomical and physiological problems.¹¹ Much of the text is entirely new, but it includes the main parts of the author's numerous descriptive, explanatory, and polemic contributions in which he has dealt with various phases of development and function and with many complicated details of animal structure. Dr. Pettigrew's object in publishing his observations and opinions regarding the various forms assumed by matter, the means adopted to produce locomotion, the numerous modifications of reproductive, respiratory, and circulatory organs, and the theories of development which have exercised so many great minds, was to show that "the resemblances of the embryos of higher forms to the adults of lower allied forms afford no proof that the higher forms are manufactured from the lower," and to advocate "the doctrine that like produces like in endless sequence, and that each begets only its own kind." It is probable that many readers will not be convinced by the arguments, but they will gain much pleasure from the delightful treatment of the subject, and they will admire the energy and ability of the author.

NOTES ON BOOKS.

PROFESSOR H. G. GREENISH'S *Textbook of Materia Medica*¹ is the second edition of his *Introduction to the Study of Materia Medica*, and the change of title is fully warranted by the extended scope of the work. The history and commerce of drugs are now described in a preliminary chapter illustrated by a number of photographs of original packages of many drugs as they reach this country, and the manner in which they are dealt with at the docks and drug sale-rooms. In the main part of the book, all the drugs in ordinary use are described; many illustrations accompany the text, but these are in most cases not intended to relieve the student of the necessity of handling and studying the drug itself, but to direct attention to some particular feature or to render more explicit the information given. Some use of the microscope in the study of drugs is contemplated, and many microscopic peculiarities are noted. Drugs are classed according to their nature as roots, leaves, gums, etc., and a tabular classification according to natural orders is also given.

The continued publication of pocket "Aids" to students would seem to indicate that such works are appreciated by those for whom they are compiled. In Dr. BERNARD HUDSON'S *Aids to Medicine*² we have a condensed account of all the diseases to which the internal organs are liable within the compass of 240 small pages! The author has carried out the instructions of the publishers, and only claims to aid the student in the revision of his knowledge. He has summarized the very latest work, however, and some of it may meet the reader's eye for the first time in this compressed form. Aid is usually sought only when difficulties arise, and it would seem hardly necessary to fill up the pages of a pocket reference book with the axioms of medicine when so many of the problems are awaiting solution. Condensed information should be accurate; but even in the more familiar accounts there have crept in certain inaccuracies which might well have been avoided.

The first volume of the nineteenth series of *International Clinics*³ for 1909 is an exceptionally interesting number. The first article, on the hospital for advanced cases of tuberculosis, by Dr. Lawrence F. Flick, is suggestive; its keynote is in the opening sentence, "The hospital for advanced cases of tuberculosis and for early cases in the acute stage of the disease is our most valuable asset in the crusade against tuberculosis. . . . It strikes at the root of the disease by bringing contagion under control when it is most intense." The theme developed in the paper will surely become a pressing issue in this country as well as in America. Among the other interesting papers are those on occupation and so-called rheumatic pains, by Dr. J. J. Walsh; on Mikulicz's disease and allied conditions, by Dr. C. P. Howard; on acute tuberculous rheumatism, by Professor A. Poncet and Dr. Lericque; on typho-bacillosis, by Professor Landouzy; on sporotrichosis, by Drs. Duval and Vinard; and one on absorption from the peritoneal cavity, by Professor W. J. MacCallum, of the Johns Hopkins University. Besides these and other lectures, the volume contains a valuable review of the progress of medicine during 1908, dealing respectively with treatment, medicine, and surgery.

MR. E. G. CLAYTON'S *Compendium of Food-Microscopy*⁴ is stated in the preface to be principally a revised issue of the microscopical portion of the works of Dr. Arthur Hill Hassall, together with additional matter and illustrations by Mr. E. G. Clayton himself. The preface and the opening "Summary of Dr. Hassall's Life-Work" show clearly the strong veneration felt by the writer for the original author of the work which is here reproduced; but if the end in view was to produce a book of as much value in food analysis to-day as Dr. Hassall's book was when it appeared thirty-two years ago, a more critical spirit might have been shown, and some of the older matter could well have been sacrificed and recent knowledge more adequately given. Thus five pages are devoted to descriptions and

illustrations of various adulterants of tea, their importance being qualified by such remarks as "it is doubtful whether lic-tea now finds its way into the English market," and "it is extremely unlikely that such articles as these in this country are anywhere obtainable at the present time. They are described here as curiosities of the past," while in the descriptions and illustrations of tea itself no reference is made to the large stone cells or idoblasts which form one of the most characteristic elements of the leaf. In a "compendium," too, a more complete list of materials might fairly be expected than is here given; thus, the *Nat. Ord.*, Umbelliferae, is represented only by cummin, which is principally used in veterinary medicine, while caraway, which are largely used in foods, are omitted, and yet room is found for ipecacuanha, scammony, and other drugs. For the most part the illustrations, which are mainly of microscopic preparations, are excellent, and show clearly the salient features; and as there are some 280 pictures, the book cannot fail to be useful, in spite of its obvious faults and limitations.

The seventh edition of *Sonshall's Materia Medica*⁵ has been revised and brought up to date by Mr. E. W. MANN. The book, as the preface states, is a compilation, but the work has been well done, and as is to be expected in a seventh edition, hardly any errors are to be found. It is intended as a companion to practical study of the drugs themselves, and hence contains no illustrations; judicious use is made of different kinds of type in distinguishing between official and unofficial substances, and between the essential and the less important parts of each subject. The list of drugs dealt with is very comprehensive.

⁵ *Sonshall's Organic Materia Medica*. By John Barclay, B.Sc., Lond., F.C.S. Seventh edition. Revised and enlarged by E. W. Mann. London: J. and A. Churchill. 1909. (Demy 8vo, pp. 376.)

MEDICINAL AND DIETETIC PREPARATIONS.

Digalen.

THE partial supersession of digitalis by its active principle, such as has occurred with several other powerful drugs, has been hindered by the absence of certain knowledge with regard to what this is. It is now generally agreed that of the many substances obtainable from digitalis leaves, digitoxin is the most powerful and reliable, and represents in its therapeutical action the entire drug; but its insolubility makes it unsuitable for hypodermic injection, which reduces the convenience of administering it by the mouth. Some time ago Dr. M. Cloetta claimed to have prepared from digitalis an amorphous digitoxin, possessing the same elementary composition as the crystalline, but being much more soluble. A solution of this amorphous digitoxin is now being supplied under the name "Digalen" by Messrs. F. Hoffman-La Roche and Co., Basle; it is stated to possess the full therapeutic properties of digitalis, and to be suitable for administration by the mouth or by enema, as well as by hypodermic or intravenous injection. A sample which was submitted was a clear colourless liquid, containing both glycerine and alcohol, and freely miscible with water. It gave the colour reactions for digitoxin as well as could be expected in the presence of large excess of glycerine.

NATIONAL ASSOCIATION FOR THE FEEBLE-MINDED.

The annual meeting of this association was held at the Mansion House on May 13th under the presidency of the Lord Mayor.

Dr. SAVAGE, in an opening address, emphasized the national importance of the question in view of the alarming increase of the feeble-minded class, which had been estimated as numbering, in England and Wales alone, about 140,000, of whom some 66,000 urgently needed special provision. Inasmuch as heredity was the preponderant factor in causation, and "prevention was better than cure" (which, indeed, was impracticable), the only remedy seemed to lie in the adoption of measures for the early detection of the unfit and the prevention of their propagation.

Mr. MONTAGUE CRACKENTHORPE, K.C., pointed out that, both from the humane and the economic aspects, it behoved society to protect itself from the criminal tendencies into which the uncared for feeble-minded so often drifted. An industrial farm colony, such as was

¹ *A Textbook of Materia Medica*. By Henry G. Greenish, F.I.C., F.L.S. Second edition. London: J. and A. Churchill. 1909. (Med. 8vo, pp. 640; 259 illustrations.)

² *Aids to Medicine*. By Bernard Hudson, M.D., M.R.C.P., Assistant Physician to the City Road Chest Hospital. London: Baillière, Tindall and Cox. 1909. (Fcap. 8vo, pp. 260; 5 illustrations. 3s.)

³ *International Clinics*. Edited by W. T. Loogooe, M.D. Vol. i. Nineteenth series, 1909. Philadelphia and London: J. B. Lippincott Company. 1909. (Roy. 8vo, pp. 316. £1 15s. four volumes.)

⁴ *A Compendium of Food-Microscopy*. By E. G. Clayton. London: Baillière, Tindall and Cox. 1909. (Demy 8vo, pp. 471, 282 illustrations. 10s. 6d.)

contemplated by the association, would meet a great social want.

Mr. W. H. DICKINSON, M.P., referred to the circumstances leading to the appointment of the Royal Commission, of which he was himself a member, and to its findings and recommendations. He combated the view that the feeble-minded formed a harmless element in the community, for in that class existed a potentiality for even serious crime. At the best they were a drag upon progress; workhouses and prisons were powerless to reform them; nothing less than real industrial colonies, specially organized, would suffice. The association had raised a certain amount of money for this purpose and had a suitable property in view, but to realize this useful scheme several additional thousands were required. He moved a resolution expressing the opinion that the facts brought out by the Royal Commission proved the existence of a grave national evil urgently requiring to be remedied, and pressing upon Government the need of early legislation on the lines of the Commissioners' recommendations.

Lady FREDERICK BRUDENELL-BRUCE seconded the resolution.

Dr. A. E. TREGGOLD, speaking from experience as a medical investigator to the Royal Commission, pointed out that the problem of how fitly to deal with the increasing number of degenerates was one of vital moment to the nation, and one of which the general public had not yet grasped the importance. In England and Wales alone there were nearly 140,000 persons suffering from original mental defect (apart from the insane)—a proportion of 1 to 248 of the population; and it must be borne in mind that mental unfitness had innumerable ramifications and correlations deeply affecting social conditions. It was high time for the nation to stem the advancing tide of degeneracy, instead of dwelling simply upon the glories of the past. Unfortunately, feeble-mindedness did not tend to sterility; indeed, he had found a larger average of children in degenerate families than in others (7.3 as compared with 4.63), and unless means were speedily adopted to check the increase of the unfit, national decadence seemed inevitable. Their propagation must be prevented, and their happiness and freedom from criminality secured, by early training and permanent segregation with useful employment in an industrial colony such as it was the ambition of the National Association to establish.

In conclusion a vote of thanks, moved by Sir WILLIAM CHANCE (Chairman of Executive Committee), and seconded by Sir R. BIDDULPH MARTIN (the Treasurer of the association), was heartily accorded to the Lord Mayor.

The thirteenth annual report of the association shows that during 1908 there had been a steady expansion of its work. New centres around London and in the provinces had been organized, additional homes affiliated, and local after-care committees had been co-ordinated in their methods, and their results compared and tabulated. The honorary medical staff had been strengthened by the addition of several provincial consultants; and lectures had been given under the auspices of the Education Committee. The Colony Fund had benefited by an increase of £1,514 during the year, and altogether about £3,000 seems now available for this object. Much more, however, is needed; and donations would be gratefully acknowledged by the Secretary, Miss A. H. P. Kirby, Denison House, Vauxhall Bridge Road, S.W.

LYNN THOMAS AND SKYRME FUND.

Report by the Honorary Secretary.

THE establishment of this Fund was announced in the BRITISH MEDICAL JOURNAL and in the *Lancet* of March, 1908. A full account was then given of the reason of the Fund and the manner of its inception, and to that account the reader is referred. The amount of money required to reimburse Mr. Lynn Thomas and Dr. H. E. Skyrme was £3,197 12s. 3d. The Fund was formally closed on July 31st, 1908. Since that date a few additional subscriptions have been received, and the gross amount of the Fund, with interest, is now £1,788 11s. 6d. All the details of the subscriptions have been published, lists appearing from time to time in the BRITISH MEDICAL JOURNAL and the *Lancet*. The amounts of individual subscriptions have varied from £10 10s. to 2s. 6d.

An analysis of the subscriptions appears in the statement of accounts below; 1,663 subscriptions were received from individuals, while 29 medical societies and 14 Branches or Divisions of the British Medical Association sent subscriptions from their general funds. To the honorary secretaries of these bodies Mr. Sheen, the Honorary Secretary of the Fund, wishes to express his sincere thanks for the help they gave.

The expenses of collecting the Fund have amounted to £176 8s. 9d. A great amount of correspondence was involved, necessitating much circularizing, stamps, clerical assistance, typewriting, and printing. Also, there was some expense in preparing the "protest," which was signed by foreign surgeons. The net amount to be handed over is £1,612 2s. 9d., so that each of the two gentlemen concerned will be reimbursed to the extent of half of his expenditure.

The result cannot be regarded as otherwise than satisfactory. The medical profession is not a rich one. The enormous mass of correspondence which has come to hand shows a feeling of universal sympathy with the two gentlemen concerned and approval of the methods of treatment they employed. Many letters of sympathy have been received from those who regret their inability to contribute.

Presentation of the Fund.

The presentation of the Fund will be made at Cardiff on June 24th next by M. J. Lucas-Championnière, President of the International Surgical Society. M. Lucas-Championnière will on that day give an address to the Cardiff Medical Society on the Modern Treatment of Fractures. To this address, besides the local profession, all subscribers to the Fund will be invited. In the evening a dinner will be given, in the course of which the presentation will be made.

No more appropriate member of our profession could be chosen to make the presentation than M. Lucas-Championnière, not only because of his position as President of the International Surgical Society, but because he is the pioneer of the present rational treatment of fractures. It was the carrying out of the methods of treatment advocated and practised by M. Lucas-Championnière that helped to involve Mr. Lynn Thomas and Dr. H. E. Skyrme in litigation. The sympathy shown by M. Lucas-Championnière, and his approval of the methods employed, has been undoubted from the first, and his opinion was expressed in no uncertain terms in an article which he contributed to the BRITISH MEDICAL JOURNAL on March 28th, 1903. The visit of so distinguished a surgeon to this country is a matter for congratulation and it is hoped that members of the profession will unite in large numbers to give him a cordial welcome, and express in every way possible their appreciation of his visit. His reception in Cardiff will be of a civic character, and he will be the guest of the Lord Mayor.

LYNN THOMAS AND SKYRME FUND.

Honorary Secretary's Statement of Receipts and Expenditure.

Receipts.		Expenditure.	
	£ s. d.		£ s. d.
To 374 subscriptions received by Hon. Sec. direct	1,365 14 0	By printing and stationery	64 5 9
To 850 subscriptions received through Hon. Sec. of Branches and Divisions B.M.A.	166 9 0	By stamps	61 1 10
To 119 subscriptions received through Hon. Secs. of medical societies	37 12 0	By incidentals	4 5 11
To 14 subscriptions from general funds of Branches or Divisions of B.M.A.	65 8 0	By clerical work	44 2 7
To 29 subscriptions from general funds of medical societies	113 12 6	By expenses of circuit, Western Australian Branch, B.M.A.	1 9 8
To 3 subscriptions from Hospital Staffs	11 19 0	By translation of "Protest"	1 1 0
To "Some Indian Sympathisers"	1 1 0		
To interest received from bank deposit	26 16 0	By balance at bankers	1,612 2 9
	1,788 11 6		1,788 11 6

I have examined the above account with the Honorary Secretary's books, vouchers, etc., and certify it to be correct.

Cardiff, May 12th, 1909.

R. H. March, F.C.A.

LLANDRINDOD WELLS.

A short time ago the authorities of Llandrindod Wells issued invitations to the members of the staffs of leading hospitals in Great Britain and Ireland to pay a visit to this spa as the guests of the town, and so many proved able to accept that the gathering last Saturday was of quite a representative character. The proceedings included luncheon in the Albert Hall, at which the chair was taken by Dr. J. Murray, M.O.H. for the district, and Chairman of the Llandrindod Development Association. On the toast list the place of honour was given to "Our Medical Guests," this being proposed by Dr. Murray himself and answered by Dr. Sainsbury of the Royal Free Hospital, London, and Professor Magee Finny, of Dublin. The rest of the afternoon was spent in examination of the resources of the place, while on Sunday morning a special sermon was preached by the Bishop of Swansea. Later in the day expeditions were paid to places of interest, and a good many medical men were the guests of Mr. Venables Llewelyn, at Llysdyman Hall, some five miles from Llandrindod. Throughout their stay the visitors had the advantage of the ciceronage of local medical men, and in addition to Dr. Murray must feel especially indebted for their courtesy to Messrs. Kerr, Hudson, and Ackerley. There was plenty to see, as changes have taken place even in the few years that have elapsed since the last occasion on which the town was visited by any considerable number of medical men, namely, at the date of the annual meeting of the British Medical Association at Swansea.

Its rapid development is somewhat remarkable. Its waters have been known, of course, to possess value from very early times, and about the time when Bath was at the zenith of its glory a speculator from over the border opened a pump room and a kind of hotel at Llandrindod. Nevertheless, it is only within the last two decades that Llandrindod has made any real attempt to vie with other places of like claims. As it now stands, it is a completely equipped Kurort, but in other respects is probably as little like what the newcomer unconsciously expects to find as could be imagined. Instead of an old-fashioned town with a spa built on to it, it is practically an entirely new creation. A brand new hamlet of red brick houses, with broad, excellently paved streets, electric lighting, refuse destructors, and septic tank sewage system. Indeed, except for the fact that the houses and streets are freely interspersed with gardens and open land and scattered over the sides of half a dozen little hills, the town in point of modernity is own sister to any of the more wealthy and up-to-date suburbs in the neighbourhood of London. At first this may be rather of a shock, but it is soon realized that the town is so microscopic that one can step in a minute from the centre of advanced civilization into the wilds of Wales.

As for its claims to be regarded as a Spa of the first order, these are unquestionable. It has two distinct pump

rooms and two distinct bathing establishments, both the latter being fitted with every form of bath and electro-therapeutic apparatus which modern hydrotherapeutic ingenuity has devised. These two pump rooms and bath houses lie at different levels of the town, but are within five minutes' walk of one another. Between them they are able to boast of as many as seven different springs, each providing a water of constant but materially different composition to that of its neighbour. This is a noteworthy point, for at first sight it seems strange that the waters obtained from springs in such close proximity should differ so very greatly in medicinal character. However, a little study of the geology of the district makes this fact fairly comprehensible. Back in the bygone ages some volcanic outburst has crushed the various strata of rock, and, tilting them at all angles, has allowed of waters of totally different characteristics rising from the ground practically side by side.

In general composition the springs fall under the headings of muriated saline, muriated sulphur, and chalybeate sources. The sulphuretted-hydrogen waters are of several strengths, one being an almost pure sulphur water.

Two of the springs have only been discovered within the last year or two. One of these, besides some sulphuretted hydrogen, contains a radioactive body, and the other a small amount of thallium chloride and a considerable quantity of lithia. Nearly all the waters contain traces of this metal, but in this particular source the amount is relatively considerable. It seems to be as high as 0.1 per mille as compared with 0.035 per mille, that of Royat water—and Royat

A View on the Ithon.

commonly prides itself on its wealth in lithia salts. All the waters are more or less gaseous, and all are cold.

The way in which the waters are utilized varies considerably in the practice of different medical men, but it would appear to be not uncommon to give them in combination, varying the proportions according to what are considered the special requirements of the case. In atonic dyspepsia, hepatic congestion, and the like, the alkaline muriated waters are, perhaps, usually given alone, while in gouty and rheumatic patients their use is combined with that of one or other of the sulphuretted waters. Similarly, the lithia water may be used either alone or in combination. As a whole, the morbid conditions in which their administration appears to be of the most value are those of torpid liver, chronic rheumatism, and gout. Benefit in cases of such character is easy to understand in view of the composition of the waters, but what is less explicable is that patients suffering from diabetes likewise seem to derive advantage. There seems, however, to be good evidence that this is really the case.

Apart from its waters and bathing arrangements, the spa has several material advantages. Its air is of the purest; and this is not difficult to understand, since the whole county of Radnor contains only some 40,000 souls, and the neighbouring counties also are sparsely inhabited. Its topography is also favourable. Residents describe the

town as lying on a plateau about six miles long and a mile wide, bordered by mountains of rather less than the average Welsh height. Inasmuch as the whole district lies at an elevation of some 700 or 800 ft., it may well be that the plateau idea is correct; but to new acquaintances the town and the district in which it lies seem to consist of a collection of innumerable hills and valleys. Therein lies one of the great attractions of the place. None of the ascents are forbidding in steepness, and plenty of level walking may be obtained; but the visitor is constantly tempted to explore one hillside after another, and can do so without undue fatigue.

It is, indeed, in this connexion that Llandrindod seems to have claims quite special to itself. Not only are its surroundings of the most attractive kind, but the smallness of the town makes geologizing, botanizing, fishing, and exploration of old cairns and Roman and other remains tasks of extreme ease. Nor are organized amusements lacking. Croquet lawns and tennis courts are numerous, and there are several golf links. One of them is a championship course of 18 holes winding along a hilltop at an elevation of from 1,000 to 1,200 ft., and is provided with an exceedingly comfortable club house. For those who prefer driving there are plenty of distant valleys and villages to visit, and motor cars are on hire. As for the accommodation to be found it is, like everything else in the town, of a thoroughly modern character, and the general healthiness of the district is clearly evidenced by the mortality returns. Last year the death rate was as low as 5 per 1,000. Although about six hours from London, the journey is not unduly fatiguing, for the line throughout is excellently laid, and in the early future the London and North-Western Railway expects to be able to shorten the distance materially.

On these grounds, therefore, quite apart from its claims in connexion with ordinary spa therapeutics, the place is one to be borne in mind when cases of pure neurasthenia have to be dealt with, or when a locality has to be selected for persons who are merely a little run down, and in need of change, open air, and gentle exercise. The picture which accompanies these lines is a view in the neighbourhood, and has been selected as more truly characteristic of the locality than would be a photograph of any building.

LITERARY NOTES.

We note that in the programme of the forthcoming meeting of the American Medical Association there is a "symposium" on syphilis. At another medical gathering in the States there is to be a "symposium" on cancer. Even if it be held that Venus and Bacchus naturally go together, surely cancer is scarcely a subject to be discussed *inter pocula*. The use of the word "symposium" to designate a scientific debate is a vulgarism due to ignorance of its meaning. Lest we be accused of pedantry, we will invoke the authority of one whose mind was far above any meticulous regard for verbal purism. In a letter (September 2nd, 1881) addressed to C. G. J. Romanes, who had suggested a conjoint article by a number of scientific men on vivisection, Charles Darwin wrote:

Allow me to demur to your calling your conjoint article a "symposium," strictly a "drinking party." This seems to me very bad taste.

A symposium, without excess and with the soothing accompaniment of the calumet of peace, may not inappropriately follow a debate. But to call the discussion itself a "symposium" suggests the possibility of scenes like that at the memorable meeting of the "Society upon the Stanislaw," in which the "scientific gents" might use bottles as weapons instead of "the remnants of a palaeozoic age." By a curious coincidence since writing this note we have come across in *Science* an account of a "symposium" on Correlation, which took place at the meeting of the American Association for the Advancement of Science. It is recorded that the Society of Vertebrate Palaeontologists held its meeting about the same time. Missiles for such a warfare as has been hinted at would not therefore have been wanting, and the more "vertebrate" the palaeontologists the more likely would they be to use chunks of old red sandstone and skulls of mammoths when the natural pugnacity that belongs to the scientific temperament was inflamed by a "symposium."

There is an interesting incident in the life of Beatrice Portinari which must appeal to all lovers of Dante, whether they believe that she was the poet's beloved lady or not. She was the daughter of a certain Folco Portinari, one of the most influential men in Florence, and three times Prior of the city; but his chief interest for us lies in the fact that he was the first Florentine who founded a hospital for the sick in his native town. In Edgumbe Staley's *Famous Women of Florence* it is stated that Florence at that time possessed plenty of charitable institutions for the relief of the suffering poor, but there was no establishment for the sole purpose of nursing the sick. This want was supplied by Portinari, who in the year 1285 took a house in the Piazza di Santa Maria Nuova, where he endowed 17 beds for the sick poor of Florence. It was known as the "Spedale di San Matteo," and formed the nucleus of the famous "Spedale di Santa Maria Nuova," which was built at Portinari's expense three years later. The new hospital buildings were large enough to include the ancient church of Sant' Egidio. Portinari continued to take an interest in the hospital while he lived, and this interest was shared by his wife and children, who, according to tradition, loved to visit the patients and minister to their necessities. But the most devoted of all the founder's household was Tessa, the old family nurse of the Portinari. Her charity is recorded in the inscription on a bas-relief of white marble which bears her effigy and is erected in the first cloister of the hospital. The inscription dates from the seventeenth century, but the bas-relief is obviously a fourteenth century work:

Madonna Tessa, represented in this bas-relief, was the servant of Folco Portinari, remarkable alike for her good deeds as for her fidelity: whilst she lived she employed her leisure time with merit and renown in visiting certain houses bought by her master for the care of the infirm. By the example of her noble-hearted charity, and by her kind offices to the sick, she persuaded Folco to display his pious and generous liberality in the foundation of the hospital, to-day so magnificent, the commencement of which took place on June 23rd, 1288.

Folco died soon after the completion of the hospital, and was buried in its chapel. The stone over his grave bore the following epitaph:

Hic jacet Fulchus de Portinariis, qui fuit fondator et edificator hujus ecclesiae et ospitalis S. Mariae Nove. Decessit anno MCCCXXXIX, die XXXI Decembris. Cuius anima pro Dei misericordia requiescat in pace.

The founder did not forget the hospital in his will. He placed all ecclesiastical matters, such as appointing priests to say mass in the chapel, etc., under the Bishop of Florence for ever, and having expressed his desire to be buried in the hospital church he goes on to offer "to God, to our Lord Christ, and to the ever-blessed Virgin Mary His Mother, the said Hospital and Church, or Chapel, for the forgiveness of my sins, and for the sins of my family, and for the benefit of the infirm poor for ever. I appoint my heirs patrons-in-chief and upholders thereof." The hospital of Santa Maria Nuova still exists, a perpetual reminder of the charity of a bygone age, and the generosity of one of Florence's most noble citizens.

No reader of Dickens is likely to forget that it was on his arrival at the Golden Cross that Mr. Pickwick and his companions had their encounter with the cabman from which they were rescued by Mr. Jingle. It was at the Golden Cross, too, that David Copperfield met his old schoolfellow, Steerforth, whose interposition wrought such a change in the accommodation provided for him. A history of this classic hostelry, now the Golden Cross Hotel, has been written by Mr. Stephen E. Hutchins, who gives an interesting account of its literary and historical associations. Its existence is traced back by the author as far as 1643, for he relates that in that far-off age the sign of the inn—it was then a wayside inn at the village of Charing—was taken down by the Puritans as superstitious and idolatrous. In the golden age of coaching, coaches ran from the Golden Cross to all parts of the country, and Mr. Hutchins tells us that there is still to be seen just at the rear of the hotel, away from the roar of Charing Cross, the yard from which the coaches were accustomed to depart, with its quaint old bedroom gallery still intact. The booklet, which is illustrated with copies of old prints, will be welcomed by all lovers of old London.

STATE REGISTRATION OF NURSES.

DEPUTATION TO THE PREMIER.

ON May 13th Mr. Asquith, the Prime Minister, accompanied by Mr. Herbert Samuel, M.P., received in his room at the House of Commons a deputation organized by the Society for the State Registration of Trained Nurses.

The deputation, which was introduced by Lord AMPHILL, comprised, among others, Mr. R. C. Munro-Ferguson, M.P., Lord Morpeth, Mr. C. D. Rose, M.P., Mr. Remnant, M.P., the Hon. Geoffrey Howard, M.P., Mr. S. H. Butcher, M.P., Mr. Ramsay MacDonald, M.P., Mr. Crooks, M.P., Dr. Rutherford, M.P., Dr. Rainy, M.P., Sir Charles MacLaren, M.P., Sir Henry Norman, M.P., Sir Luke White, M.P., Mr. Arthur Fell, M.P., Mr. Field, M.P., and Mr. D. Smeaton, M.P.

The British Medical Association was represented by Sir Victor Horsley and Dr. Smith Whitaker, Medical Secretary. Dr. Bedford Fenwick, and Sir William Macewen, of Glasgow, were also present.

The leading societies of women were represented by Mrs. Alfred Emmott, Vice-President of the National Union of Women Workers; Lady Strachey, President of the Women's Local Government Society; and Miss E. S. Kerrison, Member of the Executive Committee of the Women's Labour League.

Trained nurses were represented by Miss Isda Stewart, Matron of St. Bartholomew's Hospital; Mrs. Bedford Fenwick, President of the National Council of Nurses of the United Kingdom; Miss Huxley, late President of the Irish Nurses' Association; Miss Sidney Browne, late Matron-in-Chief, Queen Alexandra's Imperial Military Nursing Service; Miss Barton, Matron, Chelsea Infirmary; and Miss Pearse, Superintendent of the London County Council School Nurses.

Lord AMPHILL, in introducing the deputation, handed the Premier a list of those present and the capacity in which they came. He thanked Mr. Asquith most sincerely for his kindness in receiving the deputation, and said they fully appreciated the sacrifice of time it involved, and would endeavour not to trespass upon his kindness by taking up too much time. The deputation was not an instance of mere importunity on the part of the promoters of a cause. Its members were sincerely persuaded that their request would not be unwelcome to the Prime Minister when he was asked to see the deputation. The idea had been entertained at first of presenting a memorial so as not to trespass upon his time, and a memorial had been prepared and signatures obtained for it, but it became known that a deputation might be preferable and might be a more convenient method generally; the promoters, therefore, had ceased to obtain signatures to the memorial, which, however, he proposed to hand to the Prime Minister, as it briefly epitomized the history of the question. The movement in favour of State registration of nurses had been in progress for twenty years, and a bill with that object had been introduced into the House of Commons for six years past. During the last session that bill had been considered with more than usual care by the House of Lords, and eventually it had passed through every stage without a division, and, having been twice in committee in the form in which it finally emerged from the House of Lords it was amended in accordance with the views of several Government departments who were concerned. Previous to that the movement had received very striking support from the professional bodies mainly concerned. In 1889 the General Medical Council passed unanimously a resolution that such legislation was desirable. Again, in the three years 1895, 1904, and 1906, the British Medical Association, embracing some 20,000 out of the 30,000 members of the medical profession in the United Kingdom, passed a resolution practically unanimously in favour of such legislation; and, on the last occasion, 90 out of 93 delegates, all elected by constituencies in which the question had been practically canvassed, supported the resolution. Following that, in 1904 and 1905, a Select Committee of the House of Commons inquired into the whole subject, and reported unanimously that it was desirable that a register of nurses should be kept by a central body appointed by the

State. Further, the opposition to the movement was considered before a Committee of the Privy Council in 1892, and on that occasion, as well as before the Select Committee of the House of Commons, the arguments against registration failed to influence the judgement of the authorities who had to decide. The movement was primarily an educational one, and its objects were to ensure that the community might have a guarantee that the trained nurses whom it employed were skilled in their professional duty. That did not obtain at the present moment, and the evil was that there was no standard, and no means of discriminating between the value of the different kinds of certificates issued by different hospitals and training schools. The public could discern no difference between a certificate given by a small private hospital with a few beds after a few months' experience and one given by the trained school of a great general hospital after a long and very varied experience. That condition of affairs was unfair to the nurses as well as to the public at large. It was unfair to the nurse who had taken the trouble to qualify in her profession by a long period of training and by considerable sacrifices, because she was on precisely the same footing as one who had had very much less training and much less experience. What the promoters of the movement were aiming at was to have nurses put on the same footing as members of other professions who stood in somewhat analogous relationship to the public. The medical profession, for instance, or such professions as those of the dentist, or druggist, or accountant, or, what was even more to the point in the circumstances, the midwife, were all subject to conditions similar to those which they desired to obtain for nurses. The midwife, who required a training of three months, and belonged to a less educated and lower social order than nurses, had at present the advantage of State registration, and had, in fact, just that which they were seeking to obtain for nurses.

IN ANSWER to an inquiry from the PREMIER, Lord AMPHILL said the deputation was not there to ask the Government to bring in a bill, but to give facilities for the passage of a bill as had been done in the case of other bills. He pointed out that there were three bills at present before the House—Mr. Munro-Ferguson's bill, Mr. Findlay's bill, and a Scottish Bill in charge of Mr. Cleland.

THE PRIME MINISTER: They are in a state of suspended animation.

Lord AMPHILL agreed, but pointed out that they could be revived in twenty-four hours. They had hoped to be lucky in the ballot, and to get their Bill before the House in the present session, in which case its success in the House of Lords would have been assured. It had been thought that the Prime Minister would like to add to the legislative achievements of the Ministry over which he presided and to give facilities for a measure which must undoubtedly be classified as one of social reform. Also it was thought, for reasons which it was unnecessary to dwell upon, that it would be desirable to do something to mitigate the very prevalent complaint that women were unable to obtain the passage of legislation which concerned them; and, further, it had been thought that from a humane point of view Mr. Asquith might regard it as pleasant in his position of immense authority and power to help those who for so long had tried hard to help themselves, and that it might be not unwelcome to him to remedy the uneven working of the Parliamentary system—if he (Lord Amphil) might so venture to speak of the system which prevailed in the House of Commons—and to give a chance to a private member's bill. The promoters of the movement thought also that Mr. Asquith might welcome the opportunity of redressing a very real grievance which existed as between the nurse, who could not get registration, and the midwife, who had that advantage, before the grievance became more prominent and more emphasized by the full operation of the Midwives Act which should very shortly come about. Finally, it was hoped that the Premier would be glad of the opportunity of giving encouragement to the nursing profession, a profession which he (the speaker) was sure it would be agreed was one of singular nobility. He thought their country could

claim to have started the profession of nursing, and, consequently, it ought to be a matter of national pride to raise the standard of nursing in this country and to continue to set an example to other countries. In conclusion, he urged that, for the reasons he had given, the Government should give such facilities as might be in its power for introducing the bill into the House of Commons that Session.

SIR VICTOR HORSLEY, speaking on behalf of the British Medical Association, said he appeared there as representing that body and its Medico-Political Committee. The Association had on repeated occasions passed resolutions practically unanimously approving of the principle of the registration of nurses.

The PREMIER inquired whether Sir Victor said there was anything like unanimity in the medical profession.

Sir VICTOR HORSLEY replied that certainly there was very nearly unanimity, because he had had the honour of being in the chair at the meeting of the Representatives of the Association at Oxford in 1904, and the votes on that occasion were about 90 to 2 in favour of registration.

The PREMIER: Do you say that that represents the opinion of the profession?

Sir VICTOR HORSLEY replied that the British Medical Association was the only body that could represent the medical profession at all. The medical profession had no other machinery whereby its views could be represented. The British Medical Association numbered some 20,000 practitioners, and sent elected delegates to the Representative Meetings, and he thought it was certainly entitled to speak in the voice of the medical profession. But even if it were admitted, for the sake of argument, that the British Medical Association did not represent the medical profession, he would, at least, say that it was the only body in the medical profession which had taken the trouble to refer bills of such a kind to a committee and thoroughly to exhaust the subject. With regard to the three bills now in being, the principle involved in Bills No. 1 and No. 2, and the principle that the British Medical Association most laid stress upon was, that the qualification of the nurse should be no longer at the mercy of private individuals, or institutions. The Association felt very strongly that the time had arrived when in the interests of the public, as well as the medical profession, and the nurses themselves, that the guarantee of efficiency should be a State guarantee. With regard to the Scottish Bill, that left the question of guarantee of qualification practically to the teacher alone, and the British Medical Association had always held that that guarantee ought to be furnished by a statutory constituted authority who would control the proper examination.

The PREMIER: Are all the nurses to come up to be examined?

Sir VICTOR HORSLEY: All the nurses who are fit to be on the register ought to be examined.

Answering an inquiry of Mr. ASQUITH as to where they would be examined and whether provision was made for that in the bills, Lord AMPHILL said provision was made for the Council to have general power to arrange examinations, and the Council would undoubtedly arrange for examinations to be held in convenient centres.

Continuing, Sir VICTOR HORSLEY said the point was one which had been already considered by the medical profession in the reform of the Medical Acts, and it was purely a matter of administrative convenience. He suggested that the form of protection was one with which every one would sympathize, because it protected the buyer as well as the seller; the public would gain by the fact of the nurse having a State guarantee that she was fit to nurse. From the point of view of the profession itself (or, if it was preferred, of the British Medical Association) that was exactly the same as that of the public. The medical profession wished to have nurses properly equipped in nursing knowledge, and desired that that should be obtained by a State guarantee. But more than that was wanted. They wanted the ethical status of the nurse and the discipline of the nursing profession to be secured, and from the medical profession's own experience of the working of the General Medical Council it was found that that could be best obtained by having a statutory constituted body like that Council in whose hand to place the government of the profession, which in this case was that of the nursing profession; it was believed

that only by establishing a Council of that sort would an end be put to the undoubted existing evil of unequalled medical practice by nurses which constituted a danger to the public, and also constituted a scandal within the profession of nurses themselves. Finally, he assured the Prime Minister that the British Medical Association also sympathized very much with the nurses in the promotion of their own interests, and felt that if a nurse had worked hard for years, and had had a satisfactory course of education, and had passed an examination, she ought to be entitled to receive from the State a guarantee of her being fully qualified to nurse. As regards the constitution provided by the two English bills the British Medical Association also felt that the nurses should have a leading voice in the selection of those who were to govern.

Dr. BEDFORD FENWICK said that it was important to remember that a hospital certificate once given to a nurse became her private property, and could not be cancelled or withdrawn whatever the nurse did. There was always a very great difficulty in tracing nurses once they left their hospital employment, and from that followed the fact that it was very easy to forge or sell hospital certificates; that had been very often done, so that people who had little or no training as nurses could pose as nurses and obtain work as such. Many evils followed from that, and it was dangerous to the public. Further, he desired to call attention to the fact that the public were not only powerless to protect themselves against nurses who often nursed without sufficient knowledge, but by a decision of the Court of Appeal the public were powerless to obtain redress for injuries caused by gross carelessness or negligence in nursing. That decision was given in a case in which a patient sued an institution and obtained £300 damages. The institution appealed, and the Court of Appeal held that the institution had only to send out the nurse to the patient, and then she became under the control of the patient, and if the patient was injured it was only the patient who was responsible for any damage the patient sustained. The principles of the Bill introduced by Lord Amphil, which had passed the House of Lords and was now before the House of Commons in charge of Mr. Munro-Ferguson, had been accepted by the Privy Council, the Local Government Board, the Admiralty, and the War Office, all of whom had made most valuable amendments in the passage through the House of Lords. The second bill flattered the promoters of the movement by taking their clauses wholesale, which was the sincerest form of flattery; and he thought the only difference was that the second bill required a larger Council as it asked for a Council of twenty-seven, and the Privy Council considered the General Nurses Council should not consist of more than sixteen. The second Bill also required a lower fee for examination. The third bill was a bill for Scotland alone, and Sir William Macewen, the distinguished Scottish surgeon, had been good enough to come to London in order to express the feelings of Scottish doctors and nurses with regard to it.

Sir WILLIAM MACEWEN stated he was present by reason of the very cordial invitation extended to him to form part of the deputation, on the understanding that he was to express his views and those of a considerable number of doctors and nurses in Scotland relative to State registration of nurses. He, and those whom he represented, were entirely in accord with the aim of both British Nurses' Registration Bills; they desired to obtain for nurses a recognized standard of teaching and examination for the three kingdoms, and that all nurses placed on the British Nurses' Register should have equal rights to practise as nurses in any part of Great Britain. The reason why so many Scottish nurses recorded their votes for separate registration for Scotland was due to a widespread misapprehension of the clauses of the British bills which at the time had not been seen by the Scottish nurses; they were misled by erroneous statements which were current regarding the bill, such as, for instance, that Scottish nurses would have to go to London to be examined. The removal of such misapprehensions had resulted in a decided change in the attitude of the Scottish nurses, so that many who had previously been in favour of the separate Scottish Registration Bill were now in favour of a single portal system for the United Kingdom. Having given instances of such a change in feeling, Sir William Macewen pointed out that a separate Scottish bill would

act as a barrier to the progress of the Scottish nurses' because it would confine such a nurse to Scotland. Having detailed his reasons for such a statement, he said that the Scottish nurses were quite prepared to welcome and pass the highest standard of examination that might be instituted by the boards appointed by the agency of the British bills, and Scottish nurses claimed, along with their English and Irish sisters, equal rights in exercising their profession in any part of the United Kingdom, so that they might have the opportunity of gaining such position as their merits deserved.

MISS ISLA STEWART, President of the Society for the State Registration of Trained Nurses, and Matron and Superintendent of Nurses at St. Bartholomew's Hospital, handed in a number of resolutions on the subject of State registration for nurses and petitions from the St. Bartholomew's Nurses' League, the Leicester Infirmary Nurses' League, the St. John's House Nurses' League, the Chelsea Infirmary Nurses' League, and the Victorian and Bournemouth Nurses' League in favour thereof. She pointed out that the present condition of the nursing world was most detrimental to trained nurses and to the progress of nursing education, and was therefore detrimental to the sick of all classes. She contrasted the condition of medical students who obtained their education at hospitals which had to conform to and carry out the general principles of education defined by the General Medical Council with the case of nurses. Throughout the United Kingdom there was no accepted method of training nurses, nor a generally adopted system of examining nurses whose training was finished. The certificates issued by every hospital varied greatly, and their value might vary from time to time as different methods were introduced. Such a condition of affairs resulted in confusion, and it was impossible to estimate the value of a nursing certificate. It was unfair that nurses who had had their four years' hospital work should find themselves competing as private nurses with women who had only had short terms of training in special hospitals, or who had been dismissed after three or four months' training as utterly unsuitable for nursing work. Trained nurses also resented the fact that there was no means of exercising professional discipline as in the case of other professions, and that there was no means of excluding from their ranks those who brought discredit upon them. It was the earnest desire of trained nurses that Parliament should give them the means of distinguishing trained nurses from the many people who adopted the uniform without justification. In conclusion, she emphasized the fact that trained nursing was a matter of national importance. Nurses were not only entrusted with the care of the sick in private houses and in public hospitals, but were being employed in increasing numbers in the different Government departments of the country, and were at the present time being organized to help in the Territorial Forces. They had proved their usefulness to the Colonial Office and to the Indian Medical Service; many thousands were now engaged in workhouse hospitals and other positions under the Local Government Board, and were being employed in increasing numbers in the sanitary service of the country, for the prevention of diseases in schools, and teaching cleanliness and health to children, whilst the work they did for the poorest and in the preservation of public health as district nurses secured the unqualified praise of those best able to judge their work. For the reasons which she had given she urged that nurses had earned the right to ask Parliament to give them that public recognition which had been accorded to other professions, namely, a method of professional control over their education and the enforcement of discipline in their ranks—which had done so much for the advancement of other professions—and thus increase their usefulness and raise a most honourable profession to its proper position in the esteem of the public.

MISS M. HUXLEY, of Dublin, Senior Vice-President of the Society for the State Registration of Nurses, said that for twenty years she had worked to obtain by constitutional methods recognition for the nursing profession by the State. She and her colleagues agreed that a properly constituted governing body should be appointed to standardize the work of nursing education. At the present time existing schools varied in

their method of training and might be well designated as good, bad, or indifferent. Certificates were given to young women by institutions which provided no proper training—institutions in which the nurses were not taught by qualified people, and their work was not properly supervised; yet those women could go forth into the world certified as efficient, which undoubtedly they were not. There could be no question as to the importance of their work for the nation, and there was no doubt about their desire to qualify properly for it, and she was happy to say that that was one of the very few subjects upon which they in Ireland were agreed. It was not desired to exclude Irish nurses from the provision of the Act, and she earnestly begged the Premier to do all that he could to forward that for which they asked.

MR. WILLIAM FIELD, M.P., said that what the previous speaker had said, although it might be a peculiar circumstance, was absolutely true, and they in Ireland were quite agreed upon the matter.

THE PRIME MINISTER: That looks very suspicious, Mr. Field.

MR. FIELD: There is always a suspicion about everything—even about the truth. He agreed with all the arguments which had been put before the Premier, and thought the matter was one of national importance. If Mr. Asquith would throw his power and influence into the matter, and give facilities for the bill to be introduced, there would be practically no opposition, and no lengthy debate. In conclusion the speaker made an appeal to the Prime Minister to further a measure in which he would have the support of the Irish party, which produced considerable merriment.

THE PRIME MINISTER, who was received with applause, said: Ladies and Gentlemen,—I am very pleased to have the opportunity of receiving you here this afternoon and of listening to so important and representative a deputation on a subject with which, I confess, I have not myself much previous or first-hand familiarity. I understand that the object of the legislation which you are promoting is to provide, by means of a representative council, a machinery for the examination of persons taking up the nursing profession, to set up a register upon which only the names of those persons shall be inscribed who have satisfied the examination test, and to provide, under penal sections, that thereafter no one shall claim or assume to practise as a registered nurse who has not satisfied that test and has not come upon the register. That will not in the least, of course, as I understand the proposal, prevent such persons who have not complied with the test or come upon the register from pursuing the profession of nursing; and when Sir Victor Horsley said a few moments ago, in his very able speech, that the recognized nurse—that is to say, the nurse recognized by the State—is the only person fit to nurse, that would not be the necessary effect of this legislation. The unfit person, or the free-lance, if I may so describe her, would be still in a position to pursue her calling and to secure her clients and to carry on her profession just as she does now.

LORD AMTHILL: The public would take her at their own risk.

THE PRIME MINISTER: Yes, as they do now, in fact, but she would not be entitled, subject to a penalty, to describe herself directly or indirectly, as a registered nurse and as having satisfied such requirements as I understand to be within the scope of the proposed legislation. We are all agreed as to the growing importance and dignity of this great profession, as to the magnificent and indispensable services rendered to the medical profession and to the cause of humanity in the country, and I am certain that there is not a man or woman among us who does not wish to see it keep up the highest standard of efficiency both as regards skill and character, and every step that can be taken in that direction will, I am sure, command the sympathy, not only of all parties in the State, but of every English, Scottish, or Irish citizen who really cares for the best interest of his country. But here I have to deal with the question whether a particular machinery is best adapted to promote that. When my friend, Mr. Field, tells me that in Ireland they are all united, and that if we promote this legislation we shall have not only England and Scotland behind us but Ireland as well, I am bound to look at representations which have come to me from other

quarters. What do I find? Let us test the question of unanimity. I have a list of persons whose opinions are entitled to the highest respect who are absolutely opposed to this. I will not mention their names, but among them are the Chairman of the Westminster Hospital, the Vice-President of the Royal Free Hospital, the Chairman of the Middlesex Hospital, the Chairman and Treasurer of the London Hospital, the Chairman of St. Mary's Hospital, the Hospital for Sick Children, University College Hospital, the West-End Hospital for Diseases of the Nervous System, the Royal Victoria Infirmary, Newcastle-on-Tyne, and King's College Hospital, the Treasurers of St. Thomas's and of St. George's and of a number of other hospitals.

Mr. FIELD: There are none from Ireland.

The PRIME MINISTER: I am not talking about Ireland, but when I am told that there is complete unanimity and that we should have all the authorities in our favour, I think the enumeration of those hospitals is enough to show that that is not the case. I asked Sir Victor Horsley, and he said quite truly no doubt that he represented the British Medical Association, which, I agree, is representative of the body of the profession. Again, I must point out that I have here a list of the names of one hundred members of the medical profession in London (again I will not give their names) who include some of the most eminent members of the profession in many departments, particularly in the departments of obstetrics and surgery, and also something like 120 members, also gentlemen of the highest distinction, in the provinces, who are entirely opposed to legislation of this kind. Then when I come to another equally important body, the matrons of hospitals, I have here the names of 49 matrons of London hospitals, and no less than 109 matrons of provincial hospitals, who are entirely opposed to this legislation. I cannot possibly, in the face of those facts, regard this as proving anything in the nature of unanimity on the part of persons interested in medicine surgery, or nursing. Therefore I think you will agree when I say that the Government must look upon it as a matter which, for the time being, is highly controversial in the views of those most directly concerned. It is not possible to treat it, unhappily, as one of those questions which sometimes, although not often, emerge in politics when all persons are agreed and when legislation goes through by general consent. In those circumstances I do not think you can expect me to do more than promise to give the most careful and respectful consideration to the arguments you have laid before me. I admit their weight. I have not heard the other side, but I think they are, *prima facie*, very cogent arguments indeed, and, having regard to the composition of the deputation, and the authority which it possesses, I can assure you that they will be most carefully and sympathetically considered by my colleagues and myself. For the time being, however, you will agree with me that, in view of the facts I have stated, you cannot regard this as other than a question which requires very careful and detailed examination in view of all the interests concerned.

The deputation then withdrew.

A NEO-MALTHUSIAN propaganda has been set on foot in various towns of France, especially in Normandy. The municipal authorities have tried to forbid the lectures, on the ground that they are opposed to public morality. The Société Normande d'Hygiène Pratique, on the initiative of MM. Brunon, Cerné and Néé, has passed resolutions approving of the action of the municipal authorities, and expressing the opinion that if such lectures are delivered the lecturers should be prosecuted.

THE American Therapeutic Society has, at the suggestion of Professor Remington, Chairman of the Revision Committee of the United States Pharmacopœia, decided to appoint a standing committee on therapeutic research. The by-laws of the society prohibit the introduction by paper or discussion of secret, patented, or trade-marked medical products; but they are careful to test the efficacy, both by laboratory research and a thorough sifting of clinical evidence, of various drugs and preparations of drugs now contained in the *Pharmacopœia*. The committee will report on its work at the annual meeting of the society, in order that there may be placed before the profession trustworthy results of systematic investigation concerning those remedies which are in daily use.

THE THERAPEUTIC APPLICATIONS OF RADIUM: METHODS AND RESULTS.

THE INFLUENCE OF RADIUM ON CERTAIN TUMOURS OF THE BREAST, ESPECIALLY CARCINOMATA.

[FROM OUR PARIS CORRESPONDENT.]

THE articles which have appeared already in the *BRITISH MEDICAL JOURNAL* have enabled the reader to understand fully what Dr. Wickham considers the crucial point of all his research, that is, the treatment of cancer situated at some depth below the skin surface. As an example of this possibility this article will contain the results and conclusions of Drs. Wickham and Degrais in the treatment of cancer of the breast.

Clinical experience and histology have established that the radiations of radium exercise a special elective action on certain morbid cells of new formation; moreover, these rays, by reason of especially great power of penetration—the most penetrating traverse a thickness of several centimetres of lead—are able to act in the depth of the tissues; it thus became of interest to attempt the application of this dual property to neoplasms of the breast.

The first attempt dates from November 7th, 1907. Dr. Triboulet was interested in the case of a lady with a malignant growth in the left breast, but owing to the advanced age of the patient surgical intervention was deemed inadvisable. The tumour was of the size of a Tangerine orange, and was adherent to both the skin and the costal fascia: the nipple was retracted, and a little to its outer side the skin was ulcerated for an area of 2 square centimetres; the skin around was rough, like the skin of an orange, and on the point of breaking down. There was one enlarged lymphatic gland in the axilla, and acute pains were felt over the whole side of the chest. Under the supervision of Dr. Triboulet these lesions were subjected to radium. At the present time, eighteen months since the treatment, this lady is in good health, and she has no pain: there is no sign in the region of the breast or axilla to cause anxiety. All that remains is a quiescent movable nodule of fibrous consistency, which seems to have resulted from the transformation of the neoplasm.

Radium was applied in this case as follows: The attempts at filtration which Drs. Wickham and Degrais had undertaken before this date with screens of different kinds (cotton-wool, aluminium, lead protected by rubber), had shown them the way to modify the therapeutic action of the radiations; these after filtration were necessarily composed of rays less in number, but of greater penetrating power. In this case a filter of lead 1.27 millimetres in thickness was used with a thin sheet of rubber over it; the radium was applied in series of ten or twelve daily applications of one and a half hours' duration each time, followed by a period of rest for one or two months. Gradually, and without any irritation of the skin surface, the morbid process was first arrested, and then gave place to one of repair. In February, 1903, the ulcerated surface had cicatrized; the tumour had diminished in volume, was no longer attached at its base, and the skin had regained a certain amount of suppleness, the pain had entirely ceased, and progressively the signs of amelioration became more pronounced. These results were only obtained very slowly, but subsequently the method of "crossed fire" was applied; and having gained experience in dosing the rays, Drs. Wickham and Degrais were able to accelerate the process of repair.

The region of the breast lends itself especially well to the method of "crossed fire"; two apparatuses are placed simultaneously facing each other on opposite sides of the breast. By utilizing a radiation of activity 2,000 to 3,000, consisting of rays of great penetrating power, that is, the hard beta and the gamma rays, obtained by filtration through lead screens, the apparatus can be left in position all night for several nights in succession and the radioactive action in the deeper parts is greatly increased by the crossing of the rays. In certain cases four apparatus

G. P. writes: In reading the letters on the Budget I could not help thinking how well it would repay some of your correspondents to overhaul or scrap their carburetors. When an 8-10 car will only do 15 miles to the gallon on a stopping run she must be in a bad way somewhere. I possess an 8-10 2-cylinder car, which I have driven for nearly a year, and can get 33 to 35 to the gallon on my stopping runs. On a long run with only one engine stop—for lunch—I got slightly over 42 to the gallon. My car weighs practically 12 cwt. without

passengers, and can, at a pinch, take three people abreast. At 15 miles to the gallon I should be obliged to bid her a long good-bye.

MEDICUS, who is considering the purchase of a motor car for professional work, asks for opinions upon the following points:

1. What is the most economical and useful size or power of car for general work, and approximately what would be the cost of such a car?

2. Is a single, or multi-cylinder, car likely to be the more reliable for ordinary work?

3. In purchasing a car I should like to have the advice of a reliable motor engineer, as I believe by doing this I shall be relieved of a good deal of worry in connexion with the selection and purchase of a car, and at the same time obtain good value for my money. Can any medical man recommend such an expert?

4. I should like to know the cost of running a small car in order to compare it with the cost of hiring at present, such costs to be on a basis of town work.

*. * 1. 9.10 horse-power, which if an open car would cost, say, £220, and somewhat more with an enclosed body.

2. The single cylinder is equally reliable, but is a little more noisy.

3. We cannot recommend an independent motor engineer from personal knowledge, the only one we knew having given up this branch of business. Several motor engineers advertise in the *Autocar*. "Medicus" might join the Automobile Co-operative Association, 1, Albemarle Street, which has an expert adviser.

4. Particulars have been given from time to time in the columns of the *JOURNAL* of the cost of running motor cars by correspondents. (See also above.)

TYRES.

BEESSWING writes: I am a country doctor whose practice covers a large area in a hilly district, and I use my 10-12 car regularly. Tyres were my bugbear until I fitted a pair of Lynton wheels and tyres to the driving axles. I have now covered a considerable mileage and am delighted with them. The initial cost is only slightly in excess of that of armoured pneumatic tyres, and the ultimate cost per car mile is approximately half that of pneumatics. At the same time there is little appreciable difference in the riding. A friend of mine has them on the driving wheels of a 10-12 Humber, and has gone 5,000 miles with no trouble whatever.

MOTOR CYCLES.

J. M. (Cape Colony) would be glad of hints with regard to the most serviceable motor cycles suitable for negotiating rivers, drifts, and stiff hills, and free from the bad habit of breaking down twenty miles from home.

M.A. writes: In answer to "L.R.C.S.," regarding the "Wolf" motor cycle, I invested in a new one at £19 19s. some two months ago, and have run it in fair and foul weather. As far as the engine and machine is concerned I have found it excellent. It is easily started, and can be mounted by the step. By taking off the belt it can be pedalled as easily almost as an ordinary "push-bike." There is no vibration, the machinery is easily understood, and the running expenses very cheap. As a "run about" for short distances and constant stoppages for visits, this make of motor cycle should leave nothing to be desired if only the belt and its attachment could be relied upon. I have had endless trouble with the belt, which is a round one with hook connexion running over a jockey wheel. These belts either stretch unduly, slip, or pull through at the hook connexion. I have had advice from experts down to the village carpenter, and all have failed: though the village carpenter's contrivance was the best and lasted the longest. If "L.R.C.S." contemplates purchasing a "Wolf" motor cycle I should strongly advise him to buy the make which has a V belt on a direct drive, and handle-bar control. He should then have an ideal machine for short distances, or as a "run about" in general practice.

MAKERS' ANNOUNCEMENTS.

THE Wolsley Tool and Motor Car Co., Ltd., of Adderley Park, Birmingham, and York Street, Westminster, desire to give notice that to identify the Siddeley Autocar more closely with the name of the makers, they will, in future, be known as the Wolsley-Siddeley cars. The same company issues a catalogue of motor tyres and accessories; it is well illustrated and seems to be very complete, showing the prices for different makes of tyres, parts, and accessories.

HUMBER LIMITED have issued a small pamphlet describing their motor car show rooms at 60 to 64, Brompton Road, London, S.W. Trial runs will be arranged without committing the inquirer to purchase.

THE Borough of Finsbury this year has a medical Mayor, and on May 13th Dr. and Mrs. W. A. Dingle were "at home" in the Town Hall, Rosebery Avenue. A concert followed the reception of the guests, the evening ending in a dance. The company included a large proportion of medical men.

Medical News.

HIS ROYAL HIGHNESS THE PRINCE OF WALES has nominated Major R. J. Blackham, R.A.M.C., an Honorary Associate of the Order of St. John of Jerusalem.

THE late Rev. Thomas Cox, of Croydon, whose will has now been proved, bequeathed to the Croydon General Hospital a sum of £1,000.

DR. W. R. WILLIAMS, Machynlleth, has, on the nomination of the Lord Lieutenant, been placed on the Commission of the Peace for the county of Montgomery.

DR. SEPTIMUS GIBBON, for nearly forty years Medical Officer of Health for Holborn, who died on April 17th, aged 83, left estate valued at £90,304 gross, with net personality £81,762.

ON the occasion of his marriage Dr. George England Kerr, of Inverness, was the recipient of a handsome Panhard landaulette motor car and a purse of sovereigns from his patients and friends in Inverness and district.

THE annual meeting of the Durham Medical Graduates' Association will take place on Friday, May 28th, at 4 p.m., at 11, Chandos Street, London, W. The dinner will take place the same evening at the Café Royal, Regent Street, W., at 7.30.

THE May dinner of the Edinburgh University Club of London will take place at the Criterion Restaurant on Friday, May 28th. Mr. H. S. Butcher, M.P., will take the chair at 7.30. The following guests have accepted invitations to be present: The Lord Advocate, Sir Henry Craik, M.P., and Barry Paine, Esq.

THE annual dinner of the Post-Graduate College and past and present members of the West London Hospital will be held on June 16th at the Trocadero Restaurant: the chair will be taken by Dr. P. S. Abraham. Further particulars can be obtained from the Dean at the hospital.

WE are informed that Dr. A. Holdsworth Davis, after holding the position of Honorary Surgeon to the Monkwearmouth and Southwick Hospital, Sunderland, for eighteen years, has, much to the regret of the Hospital Committee, resigned his appointment, and has been succeeded by Dr. A. J. Gilbertson.

THE Croonian Lectures of the Royal College of Physicians of London will be delivered at the College by Dr. W. S. Lazarus-Barlow on Tuesdays and Thursdays, June 15th, 17th, 22nd, and 24th, at 5 p.m. on each day. The subject is radio-activity and carcinoma—an experimental inquiry.

THE annual dinner of the Indian Medical Service will be held at the Gaiety Restaurant, Strand, on Thursday, June 10th, at 7.45 p.m., Sir George Birdwood, K.C.I.E., in the chair, when the service will have the honour of entertaining General Sir O'Moore Creagh, V.C., K.C.B., Commander-in-Chief in India elect as their guest. Officers intending to be present should communicate without delay with the honorary secretary, Lieutenant-Colonel F. J. Freyer, 27, Harley Street, W.

THE following gentlemen have been elected office-bearers by the Partick and District Medical Society: President, Dr. J. Gibson Graham; Vice-Presidents, Drs. W. Snodgrass and J. Morton; Secretary, Dr. A. W. M. Sutherland; Recording Secretary, Dr. J. King Patrick; Treasurer, Dr. J. Gracie. Eight members of council, including the outgoing president, Dr. Arthur Meehan, have also been appointed. The first session of the society, which was formed last year, seems to have been very successful.

THE annual meeting of the North India School of Medicine for Christian Women was held on May 5th at Trinity Church House, Great Portland Street, London. The enterprise represented by this title is carried on at Ludhiana, in the Punjab, and has now been in progress for some fourteen years. It includes a hospital, which is apparently conducted on very active lines. Last year the new out-patients numbered nearly 20,000, and in-patients over 1,200; the number of beds constantly occupied was seventy-six, and 1,100 operations were performed. It is not a school of medicine in the proper sense of the term, as the women it trains are intended to be employed as nurses, dispensers, and hospital assistants. The undertaking appears to stand in need both of more money and of additions to its medical staff. What standard of knowledge the students of this school are expected to reach before receiving certificates is not indicated in the material which has reached our hands. Some assurance that it is sufficiently high seems desirable, since the primary object of the institution would appear to be, not education, but the spread of Christianity.

British Medical Journal.

SATURDAY, MAY 22ND, 1909.

SPIRITUAL HEALING AND CANCER.

ONE of the most serious difficulties in arriving at a correct conclusion as to the curative powers claimed for spiritual healing is the intangible nature of the evidence. For instance, most of the patients on behalf of whom prayers were asked in the earlier numbers of *The Healer*—which is published by Mr. J. M. Hickson, and which, we suppose, may be regarded as the organ of the Society of Emmanuel of which that gentleman is the president—are vaguely described as suffering from "rheumatism," "loss of nerve power," "spinal trouble," "internal weakness," "low vitality and great weakness," "heart trouble," "internal trouble." Some indeed are said to be the subjects of "locomotor ataxy" and "consumption," but no particulars are given by which the diagnosis can be checked, and it is difficult or impossible to trace the result of the treatment. In a report of the past year published in the number for November, 1908, Mr. Hickson does give some details of a few cases. The two following taken at random may be given as specimens: "Priest. Cancer in bowel. 'Specialist who examined him nine months ago under 'an anaesthetic said that an operation was impossible, and that he could not live for more than about 'three months. He then sought help through Divine 'Healing, when he was anointed with oil in the name 'of the Lord, and Mr. Hickson laid his hands on him 'in prayer, after which he was examined by the same 'Specialist, who found that a process of absorption 'was taking place. He is now quite well." "Lady's 'Maid. Age about 28. Suffering from rupture, which 'gave great pain. One year under treatment at 'Middlesex Hospital, and while waiting for an in-patient's bed for operation was advised to seek help 'through Divine Healing. After three visits to Mr. 'Hickson, two months ago, she is now quite well and 'strong, with no pain or swelling. Her mistress also 'reports that serious defects of her character are no 'longer apparent and her whole spiritual nature is 'quickened and her duties are better done."

These cases are sufficiently definite to be tested, and we should be glad if Mr. Hickson would supply us with the information necessary for the purpose. We should undertake not to publish the names of the patients or any particulars by which they could be identified. We should place the results of our investigation honestly before our readers.

In the meantime, we have succeeded in tracing a case more remarkable than either of the two just cited, and the result is very instructive. It was related in the third number of *The Healer* (March, 1908, p. 9) by the Right Rev. L. G. Mylne, D.D., formerly Bishop of Bombay, in a paper entitled "The Anointing 'of the Sick for their Healing." It has already been quoted in the BRITISH MEDICAL JOURNAL of January 9th, 1909, p. 109, but to enable the reader to form a correct judgement on the subject it must be repeated here. Bishop Mylne said: "In the latest up-to-date

"book on cancer, which is in the hands of the
"most scientific men of to-day, there is a case
"quoted which is, I have no doubt, correctly said
"to be a unique one of *abortive* cancer. The
"case is fully described from a medical point of view
"—how a patient, stricken unquestionably with
"cancer, was found to have, in place of the tumour,
"something which could only be called abortive
"cancer, the like of which was never heard of before.
"I happen to know the whole history of the case
"from the brother of the patient, himself a medical
"man. It was this: The patient had been suffering
"from a serious affection of the throat. He went to
"one specialist after another. Three eminent men
"told him without hesitation that he was suffering
"from a cancer growing on the vocal cords, and that
"nothing but their total excision could save his life.
"He was a hard-working priest of our Church, and, of
"course, the operation meant that he would never
"utter a word again. However, his life had to be saved.
"The doctors came; the throat was laid open; the
"operator had his knife in his hand to excise the vocal
"cords. He stopped dead. Instead of applying the blade
"of the knife, he took hold, between his thumb and the
"handle, of all he found there, and peeled it off just
"like the skin of a fruit. Between the diagnosis and
"the operation the patient had been anointed with oil
"in the name of the Lord. That is one of not a few
"cases which some of us know about, but it is by far
"the best defined one I know of, and one that is
"actually celebrated in medical circles; not of course
"being quoted as an instance of what may be done
"by anointing, but as a case unique in surgical
"experience." We went on to say that we should be
"glad to have fuller particulars, and we respectfully
"invited Bishop Mylne to furnish us with the name of
"the 'latest up-to-date book on cancer' from which he
"quoted.

In the meantime, we had been put on the track of the case by a distinguished physician, and had obtained a report of the case from the surgeon who operated. All, therefore, that was wanting was the name of the book from which the quotation purported to be taken. We communicated with Bishop Mylne on the subject, and we have to acknowledge the courtesy with which he received our request for information and the pains he took to procure it for us. His Lordship was, however, unable to gain the consent of those to whom he applied to help in any way in supplying an answer to a very simple question. As the matter is one of general interest not only to the medical profession but to the whole of mankind, we think it right to give the true facts of the case, of course without disclosing the patient's identity.

The operator was Mr. Butlin, who has been good enough to give us permission to publish the following account. He saw the patient, who was at that time 37 years of age, in 1890. There was then a very white patch, flat and sessile, on the middle of the left vocal cord, looking like a papillary growth. A month later the surface seemed to be ulcerated. The patient was seen by other well-known specialists, who, like Mr. Butlin himself, were puzzled as to the nature of the disease. Tubercle, papillary growth, and malignant disease were in turn considered, but no definite conclusion was arrived at. The patient was treated in various ways for four months before it was thought right to open the larynx. Mr. Butlin then operated in the presence of an eminent specialist, a distinguished surgeon, and another medical man, a friend of the patient. When the larynx was opened,

there was found to be no ulceration, although all present thought they had seen it with the laryngoscope. The diseased surface looked more like a thick patch of leukoplakia than anything else. The cord was scratched with an instrument and the patch came away clean and complete, leaving the cord underneath quite healthy. Mr. Butlin afterwards examined sections of it with the microscope and found that it consisted of horny epithelium, arranged in layers. He therefore supposes it was really a kind of leukoplakia. The larynx was closed, the patient recovered, and his singing as well as his speaking voice was restored as if nothing had ever been the matter.

Mr. Butlin adds that it was truly a very remarkable case, and one which does not quite correspond with any disease of the larynx of which he has knowledge either from observation or from reading. He does not remember ever to have published the case. This makes the quotation from "the latest up-to-date book" on cancer, which is in the hands of the most "scientific men of to-day," all the more mysterious. We cannot understand the objection which Bishop Mylne met with in his efforts to procure the reference for us, particularly as the case had been published in *The Healer* in a way which—no doubt quite unintentionally—was somewhat misleading.

It does not lie within our province to discuss the effect of the anointing with oil which is said to have taken place between the diagnosis and the operation; nor do we question either the good faith or the sound judgement of those who see in the issue of the case the manifestation of a supernatural agency. But it might have been thought that in regard to a case admittedly remarkable, they would have preferred to take advantage of the opportunity of helping to make the facts as public as possible, rather than to place obstacles in the way of their being made known.

We have only one thing more to say. As there is conclusive proof that the disease was not cancer, "abortive" or developed, the case should not be brought forward as an example of spiritual healing of that disease. We have used it here to point the moral which we are anxious to impress on spiritual healers of all shades of belief and practice—namely, that they should be more cautious and, above all, more precise, in their statements than, as a class, they have hitherto been. Moreover, they should not only verify their references, but give earnest inquirers the opportunity of doing so for themselves.

THE FEBRILE REACTION.

AN interesting and important contribution has been made by Dr. Fr. Rolly of Leipzig to the discussion of the relation of the febrile reaction of the body to infection. While many have held that fever is the natural reaction of the body to invasion by micro-organisms, a part of the defensive mechanism, others, and particularly Liebermeister, have maintained that fever is in all cases harmful; that the rise of body temperature is the actual cause of parenchymatous degeneration and fatty infiltration of the organs; and that it must be combated by vigorous antipyretic treatment.

To-day it is generally recognized that the whole process of inflammation is defensive and curative in purpose. The hyperaemia and oedema of the inflamed part signify the flooding of the infected tissues with blood plasma and phagocytes, the plasma activating the phagocytic process and neutralizing the toxins

produced. The fomentations and incisions of the surgeon and the cupping and congestive treatment of Bier are alike directed towards flooding the inflamed tissues with plasma. The success that accompanies the application of fomentations and poultices, as hot as the patient can bear them, points to the utility of the local febrile reaction. It is a well-established fact that the velocity of all protoplasmic and ferment action is diminished by cold, and increased by heat up to a certain limit. Rolly and Meltzer found that phagocytic action reached its maximum, not at 37° C., the normal body temperature, but at 39.5 to 40° C. (104° F.). By 41.5° C. (106.7° F.) the phagocytic power was significantly decreased. By placing rabbits in a well-ventilated, heated chamber, and feeding them in a suitable manner with plenty of watery green food, these authors succeeded in keeping the animals for from four to twenty days in a hyperthermic state. With a body temperature varying between 39.5 and 42.5° C. the animals remained well and healthy, and their organs, in consequence of this simple non-infective rise of body temperature, showed no signs of parenchymatous degeneration. The production of anti-toxins and agglutinins was accelerated in such warmed animals in comparison with the controls kept in a cold chamber. In respect of all the defensive mechanism the animal with a moderately-raised body temperature has the advantage over one that is kept at normal or subnormal temperature. Four rabbits of one litter which were kept in the hot chamber for days with a body temperature of 39.5 to 42.5° C. were killed and their organs contrasted with those of a fifth rabbit, one of the same litter, which was kept under ordinary conditions. Microscopic examination showed none of those parenchymatous changes in the rabbit's organs which are so easily brought about by febrile infections. The protein katabolism and nitrogen output was not increased to any notable degree so long as the body temperature was kept under 40° C., and the increase at higher temperature was very much less than in states of infective disease. Similarly Linser and Schmid observed in two brothers, who had little power of heat regulation, owing to a skin affection, that raising their body temperature to 39° C. by external warmth even for several days, had no effect on the nitrogen output, while a temperature of 40° C. and over increased it. Further, slight changes only were produced in the blood by a simple hyperthermic state as compared with the profound changes produced by infections.

It has been suggested that one function of the febrile reaction of the body on infection is to raise the temperature to a height which is unfavourable to the growth of the infecting bacteria. The evidence in favour of this hypothesis is based chiefly on observations of Pipping, who found that the growth of pneumococci on broth was influenced unfavourably by fever temperatures. Rolly and Meltzer found that this could not be the case when the organisms actually infected the body. The febrile reaction does not destroy the organisms by overheating them, but by favouring the bactericidal powers of the body. The conclusions reached are that fever temperatures up to 40° C. (104° F.) are part of Nature's cure, and should not be combated by antipyretic means unless serious symptoms of disturbance of the nervous system or of the circulation and respiration arise. Then the treatment should be directed to the relief of the untoward symptoms rather than to lowering considerably the body

temperature. To effect this warm sponging or warm baths are far more effective than cold, for the latter produces vaso-constriction of the skin and defeats the end in view, while warm sponging dilates the cutaneous vessels and the evaporation of the water effectually cools the blood.

It has been demonstrated by Pembrey and others that muscular activity raises the body temperature notably in animals and men. Leonard Hill and Martin Flack found a rectal temperature of 102° to 103° F. in students after a football cup tie or half-mile or mile races, and in two a temperature exceeding 104° F. (in one 105° F.) after a three-mile race. Stokers working in steamships in the tropics, puddlers in ironworks, miners in Cornish mines, where the temperature may be 93° F. and the air wet with moisture, dwellers in tropical regions where heat waves occur, must all, like Rolly and Meltzer's rabbits, live for periods with raised body temperature; and every man who takes violent exercise does the same.

It is doubtful whether the rectum is the most accurate place to take the temperature. It gives the highest reading no doubt, but probably the axilla gives a reading which is nearer to that of the brain, and perhaps of the heart—the two essential organs to be considered. In severe muscular exertions, when the heart is becoming exhausted, venous blood becomes pooled in the abdomen, and this raises the rectal temperature higher than elsewhere.

It must always be borne in mind that the temperature of the body varies from one part to another, and is never absolutely steady or constant anywhere. Curious and unexplained oscillations of body temperature occur from time to time; these were being studied by methods of continuous record by the late Dr. Gamgee, and results of a research which would have been of great interest have been broken short by his lamented death. To the last number of the *Proceedings of the Physiological Society* Leonard Hill and Martin Flack contributed a series of observations on the effect of hot baths on themselves and students. By immersion in water at 105° F. to 110° F. the body temperature can be raised in some twenty minutes to 102° F. to 104° F. This produces hyperpnoea, the evaporation of water from the lung being then the chief means of keeping down the body heat; the partial pressure of carbonic acid in the alveolar air is lowered by the hyperpnoea from the normal 5 to 6 per cent. to 3 to 4 per cent.; the body is not only cleansed of carbonic acid but well oxygenated by the hyperpnoea. In consequence, after such a hot bath, the breath can be held twice as long as normally. The extra oxygenation produced by the hyperpnoea and quick pulse of fever must be part of this curative reaction. The vasomotor system is so profoundly affected by the hot bath that the blood pressure may sink to 60 mm., while the pulse becomes very frequent and thready. The cutaneous vessels are greatly dilated, and most of the blood, determined to the surface.

On standing up the pulse-rate may increase by 40 beats a minute, and the subject faint from the sinking of the blood into the relaxed vessels of the lower parts of the body. All these conditions are immediately relieved by a cold douche: the skin constricts, the pulse becomes full and strong and far less frequent, the hyperpnoea ceases, and the blood pressure rises, the faintness disappears, the axillary temperature, which was equally as high as the rectal, falls to or below normal, while the rectal temperature

remains febrile owing to the driving of the blood from the skin into the abdominal organs.

A very hot bath followed by a cold douche is a means of affecting the body most profoundly, and one which the Japanese use habitually both for pleasure and as a curative agent. The temperature of the bath which the workpeople accustom themselves to resist for a few minutes is said to be extraordinarily high.

THE INDIAN MEDICAL SERVICE.

THE correspondence published as a white paper entitled "Measures for promoting the growth of an independent medical profession in India," presented to Parliament on May 20th, shows, we fear, that there are considerable grounds for the apprehension that the changes in the Indian Medical Service which the Secretary of State has directed to be carried out will seriously affect the future of that service. As will be seen (SUPPLEMENT, page 312) the matter was raised in a dispatch from the Secretary of State to the Governor-General on August 9th, 1907, referring to dispatches by Lord George Hamilton, dated as long ago as January and December, 1900, expressing the opinion that it would be a great benefit to India if medical men established themselves in private practice in that country in the same way as in other parts of the Empire without entering the medical service connected with the army. Lord Morley's first dispatch asked whether any steps had been taken to give effect to this policy. In the reply from the Government of India the whole question is dispassionately discussed; and while entire sympathy is expressed with the desire to promote the growth of an independent medical profession, the difficulties in the way of carrying out the policy proposed are clearly set forth. The general conclusions of the Government of India are that the changes should be very gradual and tentative, and in the main, but not exclusively, from the bottom, and only made as really qualified candidates become available in India, nothing being done to lower the efficiency of the medical schools and their hospitals; that a sufficient number of civil appointments should be reserved to provide for the economical employment of the war reserve of the Indian Medical Service; and that the necessity of maintaining the attractiveness of the service should be borne in mind in allotting them. Lord Morley accepts these principles, but at the same time demands an actual reduction in the numbers of the Indian Medical Service in civil employment.

The result of the proposed measures must depend on the way in which they are carried out. The Government of India fully realizes that the present European staffs of the medical colleges will become more than ever essential if the graduates they teach are to be given more responsible Government posts than heretofore, and as these posts also form one of the main attractions to first-class men to enter the Indian Medical Service, this is satisfactory so far as it goes. It is probable that some additional minor professorships to be held by Indian graduates will be created and will still further strengthen the teaching. Of more importance to the Indian Medical Service as a whole is the number of civil posts to be taken away from the officers recruited in England, and it

may be observed that the last entrance list included no less than five Indian graduates—probably as many as it will be possible to find suitable employment for. The Government of India points out that it is essential to retain sufficient civil posts to employ the Indian Army Medical Reserve, and that about half of the civil posts are so important that they can only be adequately held by Indian Medical Service officers, who could not be spared for military duty even in a big war. The remaining civil posts contain the available medical reserve for war time: and as it is these only which could at present be filled by locally-recruited Indians, it is clear that very few such posts now held by Indian Medical Service men can, with due regard to economy and efficiency, be given up to them. The local Governments have been instructed to report what posts can be so given up, and on the answers the future recruiting of the service will depend. If the civil list of the Indian Medical Service is seriously reduced in numbers, the result will be that instead of nearly two-thirds of the service being able to look forward to the civil professional opportunities which practically all enter in the expectation of attaining within three or four years of reaching India, only a minority will be able to obtain civil work, and that only after a number of years in military employ. In such circumstances it is certain that it will not be possible to "maintain the attractiveness of the Indian Medical Service" on which the Government of India rightly lays so much importance. Moreover, there is a natural fear that once a beginning is made in reducing the attractions of the service, as represented by the proportion of civil posts, the process will steadily advance, and, as recruits now entering have to look forward to at least thirty years' service in India to get the full pension, it will be quite impossible for them to foresee how far their prospects may be adversely affected after they have entered by the progress of the changes indicated.

It is earnestly to be hoped that the present uncertainty as to the future of this famous medical service will soon be settled in such a manner as fully to maintain its prospects and traditions; otherwise the standard of entries must inevitably rapidly fall: once the confidence of the medical schools of Great Britain in the future of the Indian Medical Service is destroyed, it will be exceedingly difficult to restore it.

FROM DEMOCRAT TO DICTATOR.

The political growth of Mr. John Burns appears to proceed with the bewildering rapidity of a tropical plant. It is not so many years ago that he was the rising hope of the Labour, if not, indeed, of the embryonic Socialist, party; then, after a period of more or less official radicalism, we find him a Cabinet Minister, steadied but by no means silenced by the responsibilities of office; and finally, last Saturday, he presented the country with a proposal for a dictatorship. We have no wish to criticize this course of development, and, if we are to have a dictator, Mr. Burns would probably make a reasonable if masterful tyrant. In his speech at the opening of the new municipal convalescent infirmary for London children he suggested that the President of the Local Government Board should be given a general commission to carry out such reforms founded upon the recommendations of the Royal Commission on the Poor

Law and Relief of Distress as might commend themselves to himself and his advisers, with, as a concession to his colleagues, the possible assistance in certain directions of the Home Office and the Board of Education. The suggestion, although very much on the lines of the historical development of democracies, is a little startling, and is not likely to be seriously entertained; we suspect, indeed, that Mr. Burns has no hope that it will be seriously entertained, and that his proposal was intended to be one of those apparent paradoxes which arrest public attention. The most significant part of his speech was the fear he expressed that the something which the Government must do will fall to the lot, not of this Government, or even of the next, but of the next but one. This is a roundabout way of saying that reform will, in the ordinary course of events, be postponed, for in all probability at least seven or eight years, and will then be contingent upon the accession to power of a political party pledged to this particular reform. Mr. Burns is an old parliamentary hand, he is no novice in party politics, and he has recently gained a first-hand knowledge of ministerial and departmental modes of procedure. We take it, therefore, that his speech is a warning to the country that unless a definite public opinion is expressed, Poor Law reform will be shelved until the findings of the Royal Commission have been forgotten, or the conditions have been materially changed. He does not want new commissions, a sentiment with which everybody will agree, nor does he wish to see the creation of new *ad hoc* bodies unacquainted with what has gone before. As to the meaning of this last opinion we must remain in some doubt, unless it can be taken to signify that Mr. Burns considers that the relief of distress should be added to the duties which already weigh upon the county councils. The question whether additional work can be placed upon the shoulders of these useful and long-suffering bodies is more serious than the Royal Commission probably recognized; we observe that Mr. Tonman Mosley, Chairman of the Bucks County Council, at the annual meeting of the County Councils Association on May 18th, in opening a discussion on the Poor Law Commission's report said that if the county was to be the unit, the county council with its existing organization would be preferable to a semi-independent public assistance authority responsible directly to no electors, insufficiently checked in its expenditure, and perhaps drawing away from county councils many valuable and hard-working members. Lord Belper, chairman of the Nottinghamshire County Council, who on this occasion was elected chairman of the County Councils Association, said that in his opinion it was impracticable for county councils as at present constituted to undertake the extra work, and eventually it was decided to appoint a committee to report upon the Poor Law Commission's report from the county councils' point of view.

SIGHT TESTING IN THE MERCANTILE MARINE.

THE case to which Mr. McArthur called attention recently by a question in the House of Commons (page 1262) affords another illustration of the unsatisfactory state of things existing at the Board of Trade when candidates are examined for colour vision. It appears that a Mr. Glover passed as second mate eighteen months ago, and has been at sea ever since. In March of this year he presented himself for examination for a first mate's certificate. He was then rejected on the ground of colour blindness by Captain Fletcher, who had passed him on the previous occasion. Mr. Glover then applied for a special test,

and the examiners in this final court of appeal were Professor William Watson, Assistant Professor of Physics at the Royal College of Science, and Captain Harvey. The court which sat to try the case consisted of the Chairman of the Local Marine Board, a stipendiary magistrate, a member of Parliament, two ship captains, and others, but no medical man was included either among the examiners or the court. According to Professor Watson, Mr. Glover made the most shocking mistakes by calling spectral green red, and by placing together as a match pink, blue, and violet wools, and these mistakes he made on several occasions, though he sometimes got them right. Captain Harvey gave corroborative evidence. So far no medical man had ever seen the candidate as regards his eyes, and not a single person who had seen him or heard the evidence had any knowledge of physiology or ophthalmology. Mr. Glover, however, decided that he would be examined by an ophthalmic surgeon, and he consequently consulted Dr. William Ettles, Pathologist to the Royal Eye Hospital, who stated that the candidate's colour vision was perfect, that the mistakes he had made were due to the abnormal length of time he was under examination by the non-medical witnesses, and that he considered him fit as regards colour vision to undertake any duties a ship's officer would be called upon to perform. After a brief deliberation the court found that he "is not incompetent by reason of colour blindness" to perform his duties, and his certificate is therefore returned to him." In the face of such contradictory evidence we express no opinion as to the rights or wrongs of the case, but one or two points call for consideration. Professor Watson, on cross-examination, stated that he "made a point of never failing a man unless he made a mistake several times." Does Professor Watson imagine that a collision at sea will not take place unless a man mistakes the colour of a light "several times"? No rule ought to be more insisted upon than one laid down by Dr. Edridge-Green—that a man who calls red green, or green red, or who mistakes a white (yellow) light for either on a single occasion should be rejected at once, for if he makes this mistake in the examination room, he is certain to do the same at sea when a light of unknown colour and intensity suddenly looms into view. No normal-sighted person would ever make a mistake even once. The evidence of Captain Harvey and Captain Fletcher may be passed over without comment, as they of course have no expert knowledge of the subject; but the evidence of Dr. Ettles that the candidate never made a mistake at all deserves respectful attention. Now it is obvious that someone's observations were wrong, and it seems strange that the crucial lantern test was not, so far as the published reports show, used by any one. The inquiry proves once more that the way in which colour vision is tested is inadequate. It would be ludicrous, if it were not so serious, to find that the British Board of Trade cannot get more competent people to examine candidates' eyesight than ships' captains backed up by a physicist, and cases like this will again and again recur until competent medical men with ophthalmic training are appointed examiners. We cannot decide from this evidence whether the man's colour vision was good or bad—perhaps it was as perfect as Dr. Ettles suggests, though if we believe a single word of the evidence of the other examiners he must be a person who has no right to be put in charge of a ship. We sympathize much with Mr. Glover, who may have perfect colour vision, as we are inclined to believe he has; if so, it is grossly unfair that he should be subject to all this incon-

venience and annoyance because he is examined by men who are not trained to form an opinion on the subject upon which they are asked to pass judgement. What would the public or the Board of Trade think of a court of examiners in seamanship composed of medical men and experts in physics?

CLERICAL PROTEST AGAINST THE EMMANUEL MOVEMENT.

WE learn from the New York *Medical Record* that at a special Masonic service held in Calvary Episcopal Church, New York, on May 2nd, the anthem, which had been specially composed for the occasion, was intended as a protest not only against Christian Science but also against the doctrines and practices of what may for convenience be termed Emmanuelism. The theme of the anthem is sustained by the baritone soloist, its warnings being explained and confirmed by the chorus. The soloist begins:

O Earth, Earth, hear the word of the Lord.
Be thou instructed, O Jerusalem, lest my soul depart from thee.
Shall a man make gods unto himself and they are no gods?
I have listened and heard, but they spake not aright.
They are vanity and the work of errors.
Deceive not yourselves. Ye looked for peace and no good came, and for a time of health, and behold, trouble.

Then the Chorus declares:

The way of man is not in himself; it is not in man that walketh to direct his steps.

The soloist goes on:

O ye priests! How long will ye sit still?
Who is this that darkeneth counsel by words without knowledge?
How do they say, "We are wise and the law of the Lord is with us?"
Thus saith the Lord of hosts, Lo, these have rejected the word of the Most High, and what wisdom is in them?
For they have hated the hand of my people slightly, saying, "Peace, peace," when there is no peace.

In thy sickness give place to the physician, for the Lord hath created him and given him skill, that he might be honoured in His marvelous works. Let him not go from thee, for thou hast need of him.
Of the Most High cometh healing. He hath created medicines out of the earth, and he that is wise will not abhor them.

The Chorus then explains that "Love and might no longer heal by touch, or word, or look," and that they who do God's work must read His laws in Nature's book. The soloist makes a final appeal:

How long halt ye between two opinions?

To which the response of the Chorus is:

As for me and my house, we will serve the Lord.

According to the anthem, the words of which seem to us excellently well chosen for their purpose, serving the Lord in time of sickness is to turn for help to the physicians whom the Lord hath created and to be healed by the medicines which "He hath created out of the earth," and which the wise man will not abhor. Several other protests against the Emmanuel movement and against the intrusion of the clergy into the sphere of medicine have been made in America. As the *Record* truly says, "It is a healthful and 'hopeful sign that many earnest churchmen are beginning to look askance on this sensational and 'harmful meddling of clergymen with pathology.'"

HIBERNATION AND PSYCHOSES.

AN exceedingly original and suggestive monograph, entitled *Stoffwechselpsychosen*,¹ or the psychoses of metabolism, published some eighteen months, has

¹ *Stoffwechselpsychosen. Die Störungen des Sauerstoff-gaswechsels im menschlichen Organismus.* By Dr. W. Ewald. Würzburg: A. Stube (Curt Kabitzsch). 1907. (Demy 8vo, pp. 59. M. 1.50.)

recently come under our notice. The author, Dr. W. Ewald, one of the medical officers of the Frankfurt State Infirmary, attempts to explain the etiology of some of the psychoses: he accepts with considerable reservation the statement that "mental diseases are diseases of the brain," maintaining that this only applies to the organic psychoses and to hereditary degenerative conditions. Acute and subacute "functional" psychoses, whether terminating in recovery or dementia, and manic-depressive insanity cannot, he considers, be considered cerebral diseases, but rather the result of general disorders of the whole body, the mental symptoms occupying the front of the stage because of the relatively great delicacy of neuro-cerebral response to injurious influences. So far Dr. Ewald is in agreement with most other writers, and also, in his opinion, as to the relative values of endogenous and exogenous toxins. Seeking, however, in the animal world for an example of a general change in the metabolism of the body associated at the same time with psychic alterations, Dr. Ewald was struck with the parallelism between the phenomena of hibernation and those of certain psychoses, notably, of course, stupor. Quoting, without criticism, Merzbacher's paradox that hibernation or winter sleep "is, in the first place, not a sleep, and in the second place, has nothing to do with winter," Dr. Ewald gives a summary of the bodily changes found in hibernating animals, as the result of the cause of the winter sleep, which included diminished intake of oxygen, before proceeding to discuss the various possible anomalies in oxygen metabolism in man, and the results of his experiments with regard to the specific oxygen capacity, blood alkaliescence, and other points. These are described in detail, but we need here only mention the main result, which is that all bodily diseases which produce alterations in the oxygen metabolism are accompanied by proportionate psychic alterations; diminution in oxygen metabolism being accompanied by retardation of mental processes and a depressive or apathetic emotional state, and increased oxygen metabolism by the opposite mental states. The examination of subjects of several forms of mental disease in the main supported conclusions arrived at previously on theoretical grounds. The specific oxygen capacity in epileptics, for example, fell, Dr. Ewald found, during stuporous states from 12.6 per cent. to 5.5 per cent. Also of six general paralytics examined, four were depressed and two euphoric and grandiose. The four depressed cases gave low or normal, and the two exalted patients very high specific oxygen capacities. Dr. Ewald has given a good deal of labour and thought to a subject which appears worthy of further study.

PUBLIC ACCOUNTANTS.

IN the characteristics of the movement now in progress in regard to accountants there is much that recalls the period immediately preceding the introduction of the Medical Act of 1857. Not so much in the proposals put forward respecting the future status of accountants as in the arguments used in favour of leaving things as they are. We have two bodies each claiming to be the rightful representative of accountancy, and numerous other bodies of recent growth claiming a recognition which their seniors are indisposed to accord to them. The older bodies have been accustomed to guard their portals by exacting from candidates the most convincing proof of professional capacity and personal trustworthiness, and they fear loss of dignity and prestige for the profession if they are called upon to merge themselves in a general institution. On the other hand, the public

is confused by the number of societies which claim that their members are entitled to public confidence, and there is a strong feeling among business men in general that the time has come when everything connected with accountancy should be duly regulated in the public interest. A very large share of all the business of the country is now carried on by limited liability companies, and the safety of the shareholders greatly depends on the ability and honesty with which the auditing and certifying of accounts is carried out. Hence the importance of submitting to some kind of control those who make their living by this work. It may be added that the need of some authority with whom complaints could be lodged, or whose attention could be directed to certain facts has frequently been felt by this JOURNAL when examining the accounts of charitable institutions. It was a great many years before those immediately concerned in the administration of public charities could be induced to see that it was their duty to have their accounts audited by some independent authority, and though this reform has now been effected, another evil has arisen. Accountants sometimes give their imprimatur to financial statements which do not bear examination. It is not that they are incorrect so far as figures are concerned, or that they are dishonest accounts in the common sense of the term. Nevertheless they are dishonest because so drawn up as to mislead subscribers who are unskilled in reading accounts. We have seen accounts, for instance, duly audited and signed as correct by accountants of some standing, in which by way of making out that the institution stood badly in need of assistance a sum of several hundred pounds spent in buying Consols was passed into the accounts in such a fashion as to make it appear that the income of the hospital during the year had fallen gravely short of the cost of its upkeep. It is not honest of hospital authorities to mislead their subscribers as to the real state of their finances even if no individual is thereby a penny the richer, and such dishonesty would not be permitted by accountants if these were subject to the control of some properly-constituted authority.

RESEARCH WORK ON NERVOUS DISEASES.

IF the increase of insanity and nervous disease at the present day affords grounds for some alarm, the organized effort that is being made to discover the causes of such affections by experimental research encourages the hope that means may be found to mitigate, and in time prevent, the evil. A few weeks ago we gave a summary of the work done with this object at Claybury by Dr. Mott and his collaborators. There is a similar laboratory at Morningside, near Edinburgh, where under the able direction of Dr. Ford Robertson important researches have been carried out. The West Riding and some other asylums have pathologists. Now we have the pleasure to announce that the directors of the Crichton Royal Institution, Dumfries, have decided to establish a laboratory for research on nervous and mental diseases in connexion therewith. The laboratory is to be organized on lines laid down by the Physician-Superintendent, Dr. C. C. Easterbrook, in a special report submitted on February 17th, 1909. In a report dated October 7th, 1908, Dr. Easterbrook had previously pointed out that if the institution was to keep abreast of what we may call the scientific stream of tendency it must provide, in addition to an efficient hospital and a comfortable home for the care of patients, adequate means for the pathological investigation of their maladies. The directors, after considering this report, asked the Physician-Superintendent to submit a

scheme for the establishment and organization of such a research laboratory as he proposed. This, after obtaining the opinions of a number of scientific experts, he has done in a report to which reference has already been made. His plan for the constitution and administration of the laboratory staff is briefly as follows: Three fellowships—one in clinical neurology and psychology, one in pathology and chemistry, and one in pathology and bacteriology, should be established. Each of these fellowships should be of the value of £250 a year, with quarters, board, attendance, and laundry at the institution, or an allowance in lieu of these of £50 a year. The fellowships should be tenable for one year, but renewable from year to year. Each fellow should be given periodical opportunities, at his own expense, of perfecting his studies and training in other clinics and laboratories at home and abroad. The fellows should devote their whole time to research work, and should be under the immediate direction of the Physician-Superintendent. Each one at the end of the year should make a short abstract of his work and list of published papers during the foregoing twelve months for submission to an Advisory Medical Committee consisting of the Physician-Superintendent, the Medical Commissioners in Lunacy for Scotland, the Superintendent of the Laboratory of the Scottish Asylums, and any others whom the Committee may think it advisable to co-opt. It is suggested that the fellows should be men holding a medical degree or diploma from a university of the British Empire, or a medical qualification from a recognized licensing body in the British Islands; that they should be men of wide education, with a knowledge of modern languages; that they should have had special experience in clinical work, preferably in the form of a good hospital appointment at a teaching centre; that they should have had special laboratory training and experience in laboratory methods as applied to clinical pathology. It is suggested, further, that they should be required to supply proof, in the form of published work, of their capacity to advance medical science by original research. Further information in regard to these appointments will be found in our advertisement columns. The scheme seems to us admirable in every way, and it is well calculated to increase the great usefulness of the Crichton Royal Institution, not only to its own inmates, but by the additions to knowledge which it cannot fail to be the means of making, to all who are similarly afflicted throughout the world. We congratulate Dr. Easterbrook on the breadth of view shown in his plan, and the directors of the Crichton Royal Institution on the large-minded zeal for humanity they have displayed in its adoption.

GLIMPSES OF MEDICINE IN THE FAR EAST.

In the *Boston Medical and Surgical Journal* of May 6th Dr. George Cheever Shattuck gives an interesting account of a tour round the world which he made a year or two ago. He bears testimony to the fact that the hospitals in the leper colony at Molokai have been renovated and enlarged, and states that it is hoped by careful segregation to stamp out the disease. The Government is building laboratories in which experimental work is to be conducted in the hope of discovering a cure for the disease. The hospitals at Honolulu contain comparatively few cases of tropical disease, and Dr. Shattuck was told that cancer of the stomach is so uncommon in the happy islands of which it is the capital that gastro-enterostomy has only once been performed there; cancer of the breast is still more rare. Japan was next visited. At Tokio our medical Ulysses found the hospital attached to the

university large and well appointed for surgery, but he judged, from the few attendants to be seen, that the patients receive little care. More interesting to him were the Imperial Institute for Infectious Diseases, the Serum Institute, and the Lymph Institute, all controlled by the Government under the general management of Professor Kitasato. Some 200 horses and cattle are kept for making serums; these are laboratories which supply vaccine and antitoxin for the entire nation; there is a special rat-proof and fly-proof building for the *Bacillus pestis*; a small hospital to which cases of infectious disease are admitted for study; and laboratories where practitioners from all parts of Japan may make themselves familiar with pathogenic bacteria and modes of prophylaxis by taking the course offered by the Government. Antitoxins for diphtheria, tetanus, erysipelas plague, cholera, and Shiga's dysentery are made in separate laboratories. Immunizing serums are prepared for small-pox, plague, cholera, and typhoid. At the time of Dr. Shattuck's visit a new antitoxin against the venom of the *habu*, a poisonous snake common in some parts of Japan, was being developed, and Professor Kitasato was experimenting with a new antitoxin for typhoid. In addition to these shrines of science, Dr. Shattuck visited the Shinto Temples dedicated to ancestor worship. In every one of these, on one side of the main hall, there sits a deity carved out of wood, with a wrinkled pot-belly and a benevolent expression. His name is Binzuri, and he heals the faithful by a sort of massage which is applied by the patient rubbing himself against the part of the body of the god corresponding to the situation of the pain in his own body. Dr. Shattuck says that from Binzuri's appearance it may be inferred that he has a large general practice, but that he specializes in headaches, joint pains, and indigestion. The votive offering is seen in Japan as elsewhere; it is common to see hanging near a shrine an array of sandals of various sizes, placed there by coolies whose sore feet have been cured by the divine power. In China the faith cure takes several forms. On the outskirts of Peking is the Temple of the famous Bronze Horse, who treats patients as does Binzuri in Japan. The horse is an archaic, stiff-legged, bronze pony of nearly life size, and he is polished all over by the sufferers. Another form of faith cure is seen at the fairs frequently held in Peking for the sale of household utensils, clothing, condiments, toys, and bric-a-brac. In a separate booth at one of these fairs Dr. Shattuck saw a doctor surrounded by an odd collection of relics, among which were some dried reptiles and the skull of a tiger. He offered for sale a black ointment compounded of the ingredients represented by the collection. At Hong Kong Dr. Shattuck visited the great Tung Wa Hospital, built by the Chinese for the poor of their race. It has two divisions, in one of which patients are treated on the Chinese system, while in the other Western methods are employed under the direction of a Chinese doctor trained in the United States. Unfortunately, no comparative figures showing the results are given. Dr. Shattuck was told, however, that patients suffering from beri-beri, which is very common at Hong Kong, often ask to be transferred to the western division in order that they may get morphine for the relief of the neuritic pains.

THE PERSISTENCY OF ANTIVIVISECTION MYTHS.

MANY things are killed by exposure; the antivivisection myth seems to flourish on it. Some correspondence which has recently appeared in the *Hull Daily Mail* affords a striking illustration of this. With the object of stirring up his fellow-citizens to attend

a meeting to protest against vivisection a Mr. Ronald Dixon cited the following example, purporting to be taken from *Vivisection: Is it Justifiable?* by the late Dr. Charles Bell Taylor: "Here is another, also called a moral experiment, which I quote from a speech by Dr. Shaw, delivered quite recently before the Royal College of Surgeons of Ireland. 'The operator began by treating the animal kindly, and winning its love and confidence. When these were secured, he cut off an ear of the dog, who looked astonished, but manifested no resentment. Next day he cut off a paw, and a few days afterwards another. Thus he went on from one outrage to another, slashing and stabbing till the experiment was complete. It was astounding how much the animal endured before his confidence was gone, and his love turned to hate. After the second paw was removed, he continued to gaze up into his master's face, and to lick the hand that maimed him.'" A controversy followed, in which Mr. Dixon said, in reply to Dr. Arthur H. Fullerton, who had asked if Dr. Taylor had seen the experiment described: "If Dr. Fullerton doubts the word and evidence of Dr. Bell Taylor and Dr. Shaw he doubts at least one of the noted leaders of his own profession, and reflects also to some extent upon the Royal College of Surgeons of Ireland, etc." This shows the antivivisectionist notion of evidence. It would be amusing if it were not so serious a thing that the public should be misled in regard to animal experimentation. For the benefit of the controversialists who, after making an inaccurate statement, hasten to take cover behind some one else, we may state that Dr. Bell Taylor was not recognized as a leader by his profession, and Dr. Shaw, on whose authority he seems to have taken the story without any independent inquiry, was not a member of the profession at all. The truth of the matter was set forth in the *BRITISH MEDICAL JOURNAL* of April 18th, 1908, p. 952. We need not repeat it in detail here; it need only be said that Dr. Shaw, a doctor of laws, related the experiments not before the Irish College of Surgeons, but at a meeting of the Senate of the University of Dublin, held on June 14th, 1892, with the object of preventing honorary degrees being conferred on Burdon-Sanderson, Michael Foster, Charles Richet, and L. Hermann, on the occasion of the tercentenary of the foundation of the university. Professor D. J. Cunningham, who spoke on the occasion, assured the Senate that "nothing of the kind ever happened in a physiological laboratory in this country." Those in attendance, according to the *Dublin Daily Express* of June 15th, 1892, numbered sixty-four; of these, twenty-four were clergymen. The honorary degrees were duly conferred, Dr. Shaw's overstatement of the case having disgusted the Senate. But this old story has become part of the stock-in-trade of the antivivisectionists, and will doubtless be heated up again and again, and served up for the delectation of those who love to sup full of such horrors. It may be added that the "moral experiment" which no physiologist would recognize as a scientific experiment in any sense, seems to have been performed in France some seventy or eighty years ago by Brachet. We have been unable to trace the report to its original source, but assuming the account given to be true, every physiologist in this country would utterly condemn such acts as wanton and useless cruelty, reflecting indelible infamy on the man who did such things in the name of science.

THE SALE OF POISONS.

THE Pharmaceutical Society of Great Britain held its annual dinner at the Holborn Restaurant on May 18th, the chair being taken by the President for the year,

Mr. J. Rymer Young of Warrington. On his left he had the President of the Royal College of Surgeons, Mr. Henry Morris, and on his right Sir Dyce Duckworth, Treasurer of the Royal College of Physicians. The company was, as usual, very numerous, and included that steady Parliamentary supporter of the society, Mr. Thomas Lough; Viscount Hill, and several other representatives of the Houses of Parliament. Early in the evening came a toast to the medical profession. It was proposed by Mr. Rymer Young, who, after sketching the progress of medicine and surgery in the last 100 years, drew a well-balanced comparison between the personal sacrifices entailed on members of various professions, and then gave his vote to medical men. The response to the toast came from Sir Dyce Duckworth, who regretted that the trend of modern pharmaceutical technique had in some measure served to make the association between pharmacists and members of the medical profession less constant and intimate than formerly. His own preference was for ordinary pharmacopoeial remedies, and he regretted that among young medical men of the present day skill in the writing of prescriptions was a less common possession than it was formerly, or than it should be. The main interest of the speeches, however, lay perhaps in the references to the strenuous year's work from which the Pharmaceutical Society has just emerged, and the probable effect of an increased taxation of alcohol. Mr. Robinson, who introduced this topic, confirmed the statements that have elsewhere been made as to the serious result which increased expenditure in this direction may have on the finance of many hospitals. The new Pharmacy Act seemed to be regarded, on the whole, with satisfaction, but fear was expressed lest the Government should fail to give effect to its implied promise that the strictest supervision would be exercised over the issue of licences to sell poisonous insecticides and the like. The clause in question—introduced at the instance of the Agricultural Board—is in any case a weak feature, for there can be few farms not within easy reach of an ordinary establishment for the sale of drugs, and the facilities now offered for the purchase of poisons are clearly open to abuse. It may be argued, of course, that neither accidental nor intentional administration of poisons can be prevented by keeping their sale strictly in the hands of pharmacists, but on the other hand, it is clear that substances or liquids only obtainable on compliance with the formalities of a chemist's shop are more likely to be handled with care than those readily to be bought at any general store. As the clause originally stood the licensee would have been entitled to regard and sell as suitable for horticultural and agricultural purposes any and every drug that he pleased, and it is fortunate that the Pharmaceutical Society succeeded in getting the purview of the clause limited to arsenic and tobacco derivatives. The Act came into operation on the first of last month.

THE ROYAL SANITARY INSTITUTE.

AMONG the many claims which the Royal Sanitary Institute could make for itself, one is the possession of some quality that promotes a strong spirit of loyalty among its fellows and members. It has its foundation, perhaps, in the fact that ever since the time when it amalgamated with the committee which had formed the Parkes Museum—a collection which it has maintained and greatly extended—its work has been steady and thorough and conducted with no undue beating of drums. In any case, there is a curious similarity in the composition of its annual

gatherings; the same faces may be seen year after year, and no dinners attract a larger number of distinguished representatives of applied and theoretical science. The general note of the dinner last week was one of content at the steadily increasing recognition of the importance of sanitation; the description by Sir Alfred Keogh of the successful creation of a sanitary corps in connexion with the Territorial Army being received with special satisfaction. A further point of interest was the statement made, apparently on good authority, by Sir Francis Sharp Powell, that the Government does not intend to allow the Housing and Town Planning Bill to drop. The President of the Institute, the Duke of Northumberland, who was in the chair, dwelt, as on several previous occasions, on the inconsistency of Parliament, which imposed on local bodies a constantly increasing number of duties without putting those bodies into a position to carry them out. The main duties of local authorities—namely, provision for the care of children, the upkeep of roads, and municipal hygiene—he summed up under the term *trinodis necessitas*. He also made passing allusion to the fact that while the nation rightly or wrongly stands committed to the principle of local government, there is evidence of a tendency on the part of the central administration to endeavour to keep real control in its own hands. In the course of the evening the annual report was obtainable, and showed that the position of the Institute is entirely satisfactory. Its new premises in Buckingham Palace Road are nearly ready, and only £2,000 remains to be collected for their equipment. A plan which we have seen shows that the accommodation provided in the new building is greatly superior to that of the Institute's old home in Margaret Street. The growth in the number of fellows and members has been steady, and examinations for the various certificates of the Institute were held during last year at as many as eighteen centres in the United Kingdom, and at seven in the Colonies. Some of the figures supplied with regard to the examinations are of interest. Since they were first instituted in 1877 some 14,882 candidates have sat for examination, but of this number only 7,720 have been successful in obtaining certificates. This represents an examination mortality of 49 per cent. Clearly, therefore, the certificates granted by the Institute must represent real knowledge.

THE new Institute of Physiology at University College, London, will be formally opened on Friday, June 18th, by the Right Hon. R. B. Haldane, Secretary of State for War. The funds for the building of the institute were provided by the liberality of Mr. Ludvig Mond and Dr. Aders Plimmer and by a bequest of the late Mr. Thomas Webb.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

The Budget.—A statement showing the estimated yield in the years 1909-10 and 1910-11, and ultimately of the new and increased taxation proposed by the Chancellor of the Exchequer in his Budget speech on April 29th, has been issued. It is estimated that the duty of 3d. a gallon on motor spirit will yield this year £340,000, and next year and subsequently £375,000; the increase on motor car licences is put down at £260,000. The increase in the rate of the income tax from 1s. to 1s. 2d.—except in respect of earned incomes between £2,000 and £3,000—is estimated to yield £3,600,000 this year, less £600,000 representing the abatement of £10 for each child under 16 in respect of incomes up to £500. The

supertax on incomes over £5,000, which is 6d. in the £ upon the amount in excess of £3,000, is expected to yield half a million this year, two and a quarter millions next year, and ultimately two and a half millions, making, with the abolition of exemptions and abatements as regards non-residents in the United Kingdom, £6,720,000 (ultimately).

The Budget and the Cost of Medicines.—Mr. Robert Harcourt called the attention of the Chancellor of the Exchequer to the minimum advance of 10 per cent. in the price of spirits used by chemists, and whether he would consider possible concessions. Mr. Lloyd George replied that he was aware that the increase in duty was likely to enhance the cost of spirits to chemists, and he had undertaken to consider the point; but there were serious difficulties in the way of allowing a special rebate of duty in their case. Mr. Harcourt returned to the subject on Monday last, and by a series of questions elicited from the Chancellor of the Exchequer that he had received some representations on the subject, including one from the Pharmaceutical Society of Great Britain. With regard to the difficulties in the way of granting a rebate, Mr. Lloyd George said that it would be difficult to provide an effective check which would ensure that the spirit was used only for strictly chemical purposes and to prevent frauds which might involve serious loss to the Revenue. As at present advised, he was doubtful whether it would be possible to devise means for surmounting these difficulties.

Medical Officers (Scotland).—Mr. Cathcart Wason asked the Lord Advocate on Monday if he was aware that in certain instances the medical profession had been warned against accepting certain appointments, owing to the treatment which had been received by the outgoing medical officers; and if any protection in such cases had been taken to safeguard the interests of the poor. Mr. Ure said that he was aware that circulars had from time to time been issued by a medical association warning members of the medical profession against accepting certain appointments. In regard to the second part of the question, he had to refer to the answer given on April 29th. Mr. Cathcart Wason then asked the Lord Advocate if he would state the number of parishes in the Highlands and Islands that had from time to time, for longer or shorter intervals, been without any medical attendance for the poor, owing to the parish council medical officer having been dismissed from or resigned his appointment. Mr. Ure replied that he was not aware of any instance in which a parish had been without medical attendance to the poor under the circumstances described. When a vacancy occurred temporary arrangements were made to provide such attendance until the appointment of a medical officer was made.

Medical Inspection of Boarded-out Children.—Mr. Walter Roch having called attention by a question to the statement made in the Minority Report of the Royal Commission on the Poor Law that the children boarded out beyond the union were not as a rule medically inspected, Mr. Burns said that he had seen the statement. Provision was made in the agreements between boards of guardians and boarding-out committees for arrangements being made with a medical man for attendance in cases of sickness, and with a dentist for the care of the children's teeth. The foster parent undertook in the case of the illness of a child boarded out with him to report the matter to the committee, the home was visited once in six weeks by a member of the committee, and a report was sent to the guardians at least once a quarter on the apparent bodily condition of the child. There was no special provision requiring the children to be periodically inspected by a medical man, though this was done in a good many instances, but as they attended the public elementary schools they were subject to the same medical inspection as other children attending these schools.

The Milk Bill.—In answer to Mr. Stanier, Mr. Burns said last week that he could not fix a date for the introduction of the Milk Bill, but that he should introduce it as soon as he could. Mr. P. Snowden then asked if the right hon. gentleman was aware that more than twelve months ago

certain clauses dealing with milk in a number of municipal bills were withdrawn on the distinct understanding that the Milk Bill would be introduced last session, and that the right hon. gentleman had given previous answers similar to the one he had just given; and whether, in view of the importance of the matter, he would give a definite undertaking that the bill would be introduced at an early date. Mr. Burns said he was aware of the facts. The delay was due to the hope which the Local Government Board and the Board of Agriculture had that they might, by means other than a bill, be able to remove three-fourths of the objections that would be raised in the discussion of the Milk Bill—by an Order of the Board of Agriculture.

Vaccination Officers.—Mr. Cave asked the President of the Local Government Board whether he had ascertained what effect the Vaccination Act, 1907, and the Vaccination Order, 1907, had upon the incomes of vaccination officers; whether he was aware that certain boards of guardians had refused to entertain an application from their vaccination officers that the board should apply to the Local Government Board for permission to pay a gratuity to the officers in order to recoup them for their loss of income arising from the operation of the Vaccination Act, 1907, and the Vaccination Order, 1907; and, if so, what action he proposed to take in the matter. Mr. Burns said that he had received representations with regard to the effect of the Act of 1907 upon the incomes of vaccination officers. The matter did not appear to be one for any general action; but in some instances the guardians had, with the consent of the Local Government Board, made additional payments to the officers affected, and in some others, where complaint had been made to the Board, they had communicated with the guardians, and had made such suggestions as in the circumstances seemed to be desirable.

The Vaccination Acts.—Mr. John Robertson asked the President of the Local Government Board on Monday whether he was aware that the vaccination officer for New Cleethorpes had served Mr. W. Truman with a notice of default, threatening him with prosecution under the Vaccination Acts unless he consented to the vaccination of his son, a boy of 12 years of age; whether the unvaccinated condition of the child was discovered through the medical inspection at the school; and whether steps would be taken to prevent vaccination officers prosecuting parents of unvaccinated children in cases where such parents had not had the opportunity of making a statutory declaration of conscientious objection to vaccination. Mr. John Burns replied that a notice did not appear to have been served upon Mr. Truman, but he understood there was another case in which the vaccination officer, finding that a boy of 12 had not been vaccinated, served the parent with a notice, and perhaps this was the case referred to. The fact that the boy had not been vaccinated was discovered from the records in the possession of the vaccination officer, and not through any medical inspection at the school. It was open to the parent within a limited time after the passing of the Vaccination Act, 1898, to apply for a certificate of conscientious objection if he believed that vaccination would be prejudicial to the health of the boy. He could not interfere with the operation of the law, which made the parent liable to proceedings if he did not obtain such a certificate.

Malarial Fever Researches.—Last week Mr. Ramsay MacDonald asked the Under Secretary for the Colonies whether he had reports on the steps taken for the suppression of malarial fever by the sanitary authorities in the Bahamas, Barbados, Jamaica, and St. Kitts-Nevis; whether these reports showed that nothing of any consequence had been done in this direction by those authorities; whether the reports had been submitted to either of the schools of tropical medicine in this country, and with what result? Colonel Seely said that the report of the Advisory Committee for the Tropical Diseases Research Fund for the year 1907 (Cd. 3,992), at pp. 29, 30, 31 and 32, showed, he regretted to say, that nothing of any consequence had been done in the direction indicated at that time. The reports in question had, with the rest of the matter contained in the Blue Book, been brought to the notice of the schools of tropical medicine, but action to

be effective must needs be taken by the Governments concerned, with the co-operation of the general community. Asked further as to the steps that had been taken to secure co-operation, Colonel Seely said the Colonial Office would do all it could, and he would be glad to answer further questions on the subject. It was the fact that in small colonies the people did not take the same view as the Colonial Office did of these matters. Therefore, it was difficult to get those measures carried out, however beneficent they were.

Sight Tests (Mercantile Marine).—Mr. McArthur asked the President of the Board of Trade a question calling attention to the case of a second mate who, after being twice rejected as colour blind, was, after an investigation by the London Local Marine Board, granted a certificate. Having regard to the fact that in the three years ending 1907 out of 51 persons rejected on the ground of colour blindness 20 successfully appealed, he asked whether the Board of Trade would consider the whole subject of sight tests as affecting the mercantile marine? Mr. Churchill replied that his attention had been called to this case, and he was aware of the facts as stated in the question. It was open to any candidate who failed in the colour vision tests in the Mercantile Marine to appeal to the Board of Trade, who remitted the case to special examiners for final decision. The tests were based on the recommendations of a Committee of the Royal Society in 1892, and the special examinations were conducted with the assistance of eminent scientific experts in colour vision. The whole subject of the sight tests and the method of conducting them was under consideration.

Medical Service (India).—Mr. Kettle asked the Under Secretary of State for India whether the higher grades of the medical service of the native states of India were generally filled by Indians, to the satisfaction of the Government and the public; whether less than 10 per cent. of such positions in British India were held by Indians; and whether he was aware that the exclusion of native Indians from these well-salaried posts was regarded in India as part of the settled policy of the Indian Government. Mr. Hobhouse replied that the Secretary of State had no detailed information on the first point, but he had no reason to doubt that the answer was in the affirmative. As regards the proportion of Indians in the Indian Medical Service, that service was recruited by competitive examination, and was freely open to natives of India. It was further the policy of Government to encourage the growth of an independent medical profession in India, and to throw open to the profession in general some of the appointments now held by members of the Indian Medical Service. The Secretary of State proposed shortly to present to Parliament papers on this subject.

Sanitary Services in India.—Sir William Bull asked on Monday if the scheme proposed for the improvement of the sanitary services in India and the development of existing establishments was completed, and what special provisions were made therein to offer a career to educated natives. Mr. Hobhouse, replying for the India Office, said that the scheme had not yet been completed. The Secretary of State attached great importance to the inclusion in any such scheme of special provisions of the kind to which the hon. member referred.

The Egyptian Department of Public Health.—Mr. Ramsay MacDonald asked last week if Mr. H. C. Ross had to leave the Egyptian Sanitary Service in consequence of his zeal for stamping out malaria, and Mr. McKinnon Wood replied that Mr. H. C. Ross was never in the permanent employment of the Egyptian Department of Public Health. He resigned his temporary post under that Department when he learned that the Director-General was not prepared to promise him a permanent post in the Inspectorate in Cairo.

The Whitsuntide Recess.—Till the House of Commons rises on Thursday, May 27th, the Budget resolutions will occupy most of its time. The Finance Bill is expected to be introduced on the 26th. The holidays will be short, and the House, as at present arranged, will resume its sittings on Thursday, June 3rd.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

THE MIDWIVES SUPERVISING COMMITTEE.

THE Manchester Midwives Supervising Committee has just issued for the guidance of monthly nurses a small pamphlet containing some valuable hints and instructions on the care of women in childbirth. Special stress is laid on the supreme importance of cleanliness on the part of the nurse and the necessity for disinfection of the hands and nails, instructions for this being given. Women suffering from sore throats or discharging sores of any kind are forbidden to attend lying-in patients, while if they have been attending cases of puerperal fever they are instructed not to attend another case without thorough disinfection, which will be done free of cost by the corporation, and are advised to consult the medical officer of health as to the precautions to be taken. They are further advised as to the arrangement of the lying-in room, the giving of an enema, the washing and disinfection of the patient, and other preparations before the arrival of the doctor. They are forbidden to make internal examinations or, except under the doctor's orders, to give stimulants or to use a douche. The after-care of the mother and infant is described in detail in a simple but thorough way, and some useful practical hints are given as to what the nurse can do if the child is born before the doctor's arrival. The whole pamphlet has evidently been prepared by a practical man; it deprecates all unnecessary interference by nurses, and is well worth attention even by fully-trained nurses.

The advice that all who act as monthly nurses should be trained and qualified opens up a subject that before long will need to be more fully considered by all midwives supervising committees, for the question arises, Ought not some training to be compulsory before any woman is allowed systematically and as a business to act as a monthly nurse? There are not wanting signs that before long there may be some reaction from the present tendency among the working classes to have a midwife instead of a doctor for confinement. Women with young families and no domestic help often find it necessary, whether they have a doctor or a midwife at their confinement, to engage some person who can act as nurse for themselves and their family, and to do the cooking and general housework. In addition, the cost of the training of midwives, what they regard as the severity of their examinations, and the strict control exercised over them, together with the fact that the bona-fide midwives are gradually lessening in number, have tended to raise the fees of certified midwives. At the same time, there is some fear that the practice is growing of doctors simply attending at the time of labour for a reduced fee and only making one or two visits afterwards, or in some cases actually never visiting at all after labour is over, but leaving the after-care of mother and infant to the totally untrained nurse. In such cases it makes very little difference in cost to the patient whether a doctor or a midwife is engaged for the labour, as some additional domestic help is in either case needed, and for the sake of cheapness takes the form of an untrained nurse who will do everything required in the way of nursing and housework for a much less charge than is made by a trained nurse. Now the opportunities which such women have of doing irretrievable harm are unbounded. As showing the dangers that may result it may be noted that, according to observations made at Monsall Hospital, the incubation period of puerperal fever is not over forty-eight hours, and out of 28 cases of puerperal fever treated at the hospital where a doctor had attended at the confinement, in 8 there were no symptoms of fever for from seventy-two to ninety-six hours after labour, while in 5 cases the latent period was over five days. Similar statistics are given for midwives' cases, all showing that Dr. Gordon is probably correct in saying that "in the bulk of cases the infection is not determined by anything that takes place at delivery," and "it is not possible to exclude the female attendant as the source of infection" one or several days after labour, so that, though sepsis during labour is of course of funda-

mental importance, there is some fear that the preservation of asepsis by the female attendant subsequently is often neglected. It is here that the untrained monthly nurse may do so much damage. She is absolutely free from any control under the Midwives Act so long as she does not undertake the management of labour itself. The hints now given by the Supervising Committee she may either regard or disregard as she thinks fit. She may defy the inspector of midwives; and if the scope of her employment is widened, as there is fear it may be through the possible shortage of midwives, it becomes a serious question whether the power of supervision by the Midwives Supervising Committee ought not to be extended, for, as things are now, the advice of the committee that all persons who act as monthly nurses ought to be trained and qualified is merely the expression of opinion which has no binding force. The British Medical Association has resolutely set its face against lowering the standard of training of midwives, and rightly so, as they often have the lives of patients in their hands. It would be disastrous to allow an inferior order of midwives to exist who could take the sole responsibility of labour, but there does seem to be some reason for legally regulating the training and controlling the practice of monthly nurses, who, while not being allowed to attend labours except in company with a doctor, have yet great opportunities of doing harm after labour is over.

THE MANCHESTER AND SALFORD PROVIDENT DISPENSARIES.

A few figures taken from the annual report of the Manchester and Salford Provident Dispensaries Association for 1908 will perhaps be of service to those places that may think of starting a provident dispensary. The association has 15,348 members, a decrease of 328 on the year; the new members numbered 2,415, but there were 2,743 withdrawals. The members pay 1d. a week, and the subscription for all children under 14 years of age in any family must not exceed 2d. a week. There is an entrance fee of 6d. for each individual or 1s. for a family, and 1d. is paid for each prescription received. The remuneration of the medical officers consists of one-half of the "ordinary members' fund," and is divided according to the number of patients that each medical officer has had during the year, members being at liberty to choose their own doctor from the staff. Payments made by members for cards, medicines, cod-liver oil, or bottles are not reckoned part of the "ordinary members' fund." The balance of members' payments and other receipts go towards the expenses of management, and if any sum be left after defraying expenses, at least two-thirds of it is distributed among the medical officers.

During the year 130,620 prescriptions were dispensed, being an average of 8.5 per paying member. The expenditure on drugs, bottles, corks, and dispensing was £1,114, so that each prescription cost about 2d., but as this includes the cost of dispensing, the actual cost of the materials of each prescription was below 2d. The total sum paid to the medical officers was £1,794 15s. 3d., and as there are 15,348 members, the amount paid to the medical officers works out at about 2s. 4d. a member a year, or slightly over 1d. a week. At Pendleton, which is the largest branch, the medical officers received £498 for attending to 3,298 patients. This branch is the best for the medical men, as they receive 3s. a member a year. For this amount there were 7,141 consultations at the dispensary and 7,057 home visits, which is rather under 8d. for each visit or consultation. About 27,000 prescriptions were dispensed, and the cost of the drugs, bottles, corks, and dispensing was £195, which is under 1d. for each prescription. At the Lower Broughton dispensary the medical officers received £108 for 1,028 patients, which is about 2s. 1d. a member a year. There were 2,486 consultations and 1,630 home visits, which is about 6d. for each visit or consultation. There were 6,440 prescriptions dispensed at a cost of £70, which is about 2d. each. At the Hulme Dispensary, which is the second largest, the medical officers received £326 for 2,963 members, which is 2s. 2d. a member a year. Here the average number of prescriptions during the year for each paying member was 10.3—that is 30,640 in all, costing £216, or not quite 1d. for each prescription.

It should be noted that the payments to the medical officers as given above are clear. But though prescriptions

are provided by the dispensaries at a charge of 1d. each, the actual cost of each prescription is from 1½d. to 2½d. Thus the excess cost is a deduction from what the medical officers would otherwise receive, or in other words, the medical officers are mulcted to the extent of about half the cost of each prescription. Again, in certain circumstances for special visits out of hours the doctors are allowed to charge 1s., but this can only rarely be enforced. Female members may be attended in their confinements for 15s., paid in advance if desired by instalments. As this is distinctly below the usual fee of the district, it offers some inducement to female members to have the dispensary doctor for their confinements.

The cost of management of the dispensaries is distinctly high. Their total income, including payments for prescriptions, and not reckoning £42 balance due to treasurer, was £4,069; and out of this only £1,794 went to the medical officers, while £1,114 was expended on drugs, cod-liver oil, bottles, corks, and dispensing, £516 for collectors, £336 for rent, rates, and taxes, £43 for printing, advertising, and stationery, and the remainder went in sundry expenses. Thus the medical men received considerably under one-half of the total income. But even this hardly represents the true financial position of the dispensaries, for it is found that the association as a whole has received since 1893 about £1,261 in legacies and donations; the council has made grants of £6,448 to the various dispensaries since 1875, and has only received in return from the dispensaries £1,578 in the same time.

On the whole, as a pure charity, something may be said for the dispensaries, but that almost completely exhausts their recommendations to medical men.

LONDON.

THE FRENCH HOSPITAL.

THE forty-first annual banquet of the French Hospital was held at the Hotel Cecil on May 15th. His Excellency the French Ambassador, M. Paul Cambon, presided, and was supported by the Spanish Ambassador and many other members of the Corps Diplomatique. The Lord Mayor and Sheriffs were also present, and about 300 subscribers. In proposing the toast of the evening the French Ambassador announced that the very large sum of £4,820 had been collected, and eulogized the untiring energy of the stewards. He congratulated M. Pondepeyre, the Secretary of the Hospital, on his skilful management of the funds during the past year; the weekly expenditure on in-patients—apart from out-patients—was less than in any other hospital in London. He announced that an extension of the building was required, which would cost £4,000. The toast of the "Corps Médical" was responded to by Mr. Edmund Owen in felicitous terms, and to demonstrate how well the patients were fed he invited any gentlemen present to come to lunch at the hospital, provided they did not all select the same day. On being asked by the French Ambassador to speak, Dr. Ogilvie said: "J'ai toujours suivi le principe du pauvre Coquelin, qui disait: 'Je n'entreprends jamais un rôle avant de l'avoir étudié à fond.' Ce soir je me trouve dans l'obligation de manquer à ce principe; car, un simple désir de son Excellence est un ordre pour moi, et bien que n'ayant pas étudié mon rôle, je vais tâcher de balbutier quelques paroles. Je me sens ce soir comme un métaphysicien écossais—Savez-vous, Messieurs, ce que c'est qu'un métaphysicien écossais? C'est un aveugle, cherchant à tâtons, dans une chambre obscure, un chat noir, qui ne s'y trouve pas. Mon crâne c'est la chambre obscure, et mes idées le chat noir. En effet, Messieurs, mes pensées s'en sont allées, comme à l'automne les feuilles jaunes tombent du chêne; elles s'en sont allées dans l'azur léger, et comme un songe éphémère, elles n'ont laissé derrière elles—aucune trace. Me trouvant dans une telle condition, ce que j'ai de mieux à faire, c'est de m'asseoir, et de me taire. Avant cela cependant, permettez-moi de vous donner mon opinion sur les devoirs d'un médecin. Son premier devoir c'est de prévenir le mal; s'il n'y réussit pas—de le guérir; et s'il n'y réussit pas non plus—de soulager la souffrance et de prolonger la vie. Je finirai, Messieurs, en répétant les mots, non d'un métaphysicien écossais, mais d'un grand mathématicien français—Descartes—"S'il est possible de perfectionner

l'espèce humaine, c'est dans la médecine qu'il faut en chercher les moyens."

In replying to the toast of his health, proposed by the Lord Mayor, M. Cambon said diplomacy did not consist in making fine phrases, but in clear and frank statements.

A MUNICIPAL INFIRMARY FOR CHILDREN.

On May 17th a building erected by the Metropolitan Asylums Board at Carshalton, originally intended for use as a convalescent fever hospital, was opened as a children's infirmary by the President of the Local Government Board. The site of the infirmary, which commands charming views of the surrounding country, consists of about 130 acres. It is anticipated that the building will accommodate at least 1,000 sick and convalescent children drawn from the workhouses and infirmaries of the metropolis. Motor ambulances have been provided for patients who cannot travel by train, and it is hoped that the institution will be used for the most part for cases requiring hospital treatment and continuous nursing.

Mr. Burns, who at the beginning of his speech was interrupted by Suffragettes, whom he described as "female hoodligans," said that the condition of Poor Law children had been greatly improved during the last forty years, and the opening of the infirmary constituted a new departure in their interests. The work of such authorities as the Metropolitan Asylums Board should be judged less by the results seen at present than by the evils they had prevented and were preventing. After insisting upon the fundamental importance of the maintenance of a due sense of parental responsibility, Mr. Burns discussed the report of the Royal Commission on the Poor Laws in his most characteristic vein; he claimed that while the Commission was sitting the Local Government Board had been acting wisely on lines of which both the minority and majority of that Commission approved. The Government of the country must do something to carry out the recommendations of the report, but whether it would be this Government or the next Government, or, as he thought more probable, the next but one, which would take action it was difficult to foresee. If Parliament knew its business it would remit the report and the whole problem of Poor Law reform to the President of the Local Government Board to take such action as seemed to him necessary, to report to Parliament every three months what had been done, and when its approval had been obtained the President should have power by regulations and orders to take action at once. If the Local Government Board was not considered capable of dealing with the whole question, the aid of the Home Office might be invoked in dealing with vagrancy and the criminal aspects of the Poor Law, and that of the Board of Education in dealing with children. He did not think that more commissions or *ad hoc* authorities possessing no knowledge of what had gone before should be imported. The State and municipality must concentrate on removing from the next generation the heritage of evils which this generation had received. To care for epileptics, imbeciles, and the feeble-minded was heroic but thoughtless charity: to avoid their creation would relieve the victim of a life of misery and the community of a perpetual burden. The child was the growing man, pliable to good influences, but susceptible to the vicious, amenable to all that made for culture, health, and strength, but, owing to its innocence, very liable to suffer from degrading influences.

TREATMENT OF SCHOOL CHILDREN.

At the meeting of the Education Committee of the London County Council on May 19th the Special Committee which is obtaining estimates of the cost of medical treatment of school children reported that it proposed to obtain information only in regard to eyes, ears, and skin diseases, and to postpone inquiries as to teeth.

Mr. Graham Wallis moved to refer the report back on the ground that it would be more satisfactory if the inquiries were complete, and he hoped in the end that the Council would decide to treat teeth.

Miss Lawrence replied that the special committee were dealing with the easiest part of the problem first. It had fairly definite information as to the number of children whose eyes, ears, and skin were affected; but estimates differed widely as to the extent of bad dentition. Public opinion was not sufficiently advanced on the question to warrant the Council undertaking the treatment of teeth.

The Rev. Stewart Headlam suggested, on the authority of a dental hospital, that the treatment of teeth should be limited to children aged between 6 and 8 years, which was a critical time if the teeth were to be preserved.

The amendment, however, was lost, and the report of the special committee was received.

WALES.

HYGIENE IN THE MONMOUTHSHIRE COAL AND IRON DISTRICTS.

In his quarterly report to the Sanitary Committee the county medical officer of Monmouthshire deals with the Tredegar and Mynyddislwyn Urban Districts. It is stated that during the seventeenth and the early part of the eighteenth centuries the Tredegar district was studded with farms, the main industry being agriculture. Mining operations commenced in the middle of the eighteenth century, and marked the beginning of the destruction of the natural beauties of the locality, which to-day are replaced by townships and iron and coal refuse. Quoting from the annual report of Dr. G. A. Brown (for 1908) it is stated that the birth-rate was 39.85 and the death-rate 18.15. The birth-rate was the highest since 1903, and slightly above the average for the past ten years, while the death-rate (18.15) was well below the average of the past ten years (19.71). The infantile mortality was considerably below the average of the past ten years, and compares not unfavourably with the average infantile death-rate of England and Wales. In recent years building operations have been mainly directed to the improvement of insanitary houses and the erection of good class workmen's houses, but notwithstanding this private enterprise does not seem to cope satisfactorily with the increased demand for houses, with the result that there is a scarcity of dwelling houses and overcrowding is becoming prevalent. In November, 1908, the sanitary inspector reported that within the Council's area there were 82 cellar dwellings occupied by about 350 persons, but since then the cellar dwellings at River-Row have, as already stated, been converted into houses of a satisfactory type, while a few of the other cellar dwellings have also received attention. Much yet remains to be done with respect to the remaining houses of this type and to back-to-back houses. After referring to the system of refuse disposal, Dr. Rocy Jones states that the urban council recently erected a Horstall refuse destructor at Cwmrhos, which from its inauguration has been quite a success, and he suggests that neighbouring councils who have the evergreen problem of refuse disposal before them would do well to visit the installation. The present system of conveying sewage by sewers direct to the Sirhowy river, rendering the river during the summer months particularly offensive, as well as the pail system, will be remedied when the Sirhowy branch of the Western Valley's main trunk sewer is completed and the subsidiary sewers of the district connected with it. He recommends the urban council to consider the following matters: The conversion of all cellar dwellings, with dwellings immediately above them, into separate through houses; the provision of better and more extended facilities for the isolation of infectious diseases; the closure of the cowshed at the isolation hospital; and the provision of a proper disinfecting apparatus. Dealing with the Mynyddislwyn urban area, Dr. Rocy Jones says that the urban district, being of recent creation and rapidly growing, falls much below the standard of ideal sanitary conditions, and makes a number of recommendations.

SWANSEA HOSPITAL.

On May 12th the board of management of the Swansea Hospital had before it a scheme for additions to the institution to cost £141,000. It was pointed out that the administrative and other departments were by no means satisfactory, being only adequate as regards accommodation but considerably out of date in equipment. The utilization of a small ward to provide 8 beds and the provision of accommodation for 50 extra beds in future was advised. It was recommended that a second floor with balconies should be built over the two existing large wards; and it was stated that the electro-therapeutic room was too small, that the accommodation

for the staff was inadequate, and that the several quarters required rearrangement. The building of a small nurses' home was advised. The report will be considered in due course.

THE EBBW VALE DISPUTE.

We take the following from the *Western Mail* of May 15th:

A meeting of the Cwm and Waunilwyd Section of the Ebbw Vale Workmen's Doctor's Fund was held at Cwm, Mr. F. Griffiths presiding. Mr. Mills, general manager of the Ebbw Vale Works, wrote: We do not intend to defend any further action in this matter, and if you will instruct your solicitors to send us an account properly set forth of your demands, we shall give it our immediate and careful attention. On the subject of splitting up the old doctor's fund into sections, this is a matter entirely for the workmen themselves. In the meantime we propose to deduct the pence in accordance with the old plan, and shall retain the moneys in the hope that, before a payment is due, some arrangement or settlement shall have been arrived at. It was decided to instruct the committee to form a separate fund for the Cwm district, Mr. Mills to be approached with a view to the contribution being stopped at the Ebbw Vale Company's offices.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

ABERDEEN ROYAL INFIRMARY.

Resignation of Dr. Angus Fraser.

At a meeting of the directors of the Aberdeen Royal Infirmary, held on May 12th, a letter was submitted from Dr. Angus Fraser, Senior Physician to the Infirmary, intimating his resignation of that post. The board resolved to record their high appreciation of the invaluable service rendered by Dr. Fraser to the hospital, and through it to the sick poor of the city of Aberdeen and large surrounding district during the long period of thirty-eight years in which he had occupied the position of a physician on the staff of the infirmary; their sense of the very high honour it had been to the infirmary to have had for so long on the roll of its officials the name of one so distinguished in his profession; and their grateful recognition of the many and varied ways in which Dr. Fraser had by his sagacious counsel and his unsurpassed knowledge of the history and working of the institution contributed to its welfare and success. It was resolved to request Dr. Fraser's permission to continue his name on the staff of the infirmary as a consulting physician, and the clerk was instructed to send to Dr. Fraser an extract of the minute.

The above announcement will be of interest to Aberdeen graduates in all parts of the world, hundreds of whom have passed through Dr. Fraser's hands in the classes of clinical medicine, and the passing from active duty at the hospital of such a well-known and popular figure will occasion feelings of regret, for one can hardly imagine the infirmary without his keen face and energetic personality in the foreground. The good wishes and grateful appreciation of a multitude will go with him in his retirement, and all will hope he may have health to enjoy the leisure he has so richly earned.

PRINCIPALSHIP OF ABERDEEN UNIVERSITY.

Much interest is being taken in the selection of a successor to the Rev. Dr. Marshall Lang as Principal of Aberdeen University, and several names are freely mentioned in connexion with the vacant position. Amongst others are Professor Sir W. Mitchell Ramsay, the distinguished archaeologist, Professor of Humanity in the university; Professor Baillie, Professor of Moral Philosophy; and Professor George Adam Smith of Glasgow. Special prominence has, however, recently been given to the name of Professor Matthew Hay, who, as is well known, has for a long time taken a leading part in the business of the University Court and in the conduct of university affairs generally. There is reason to believe that the appointment of Professor Hay would meet with the emphatic concurrence of his colleagues in the university, as it would also be warmly approved by the citizens at large. The appointment is in the hands of the Secretary of State for Scotland.

EFFECT OF THE INCREASED DUTY ON SPIRITS ON HOSPITALS.

A meeting of the Dundee and District Pharmaceutical Association was held last week, when the question of the increased duty on alcohol was discussed. A motion was adopted calling the attention of Mr. Lloyd George to the injustice done to infirmaries and hospitals by the increased tax on alcohol, and expressing the desire that such institutions should be exempted because of the increased expenditure that would result. It was stated that in the case of the Royal Infirmary, Dundee, the increased annual expenditure arising out of the additional duty on alcohol would be £160 to £180, Edinburgh Royal Infirmary and Sick Children's Hospital between £500 and £600, the Glasgow Infirmary between £800 and £900, and Aberdeen Royal Infirmary about £160.

CEREBRO-SPINAL MENINGITIS IN SCOTLAND.

The Registrar-General for Scotland reports that during the month of April, in eight of the principal towns of Scotland, 8 deaths were from cerebro-spinal meningitis. This was 4 fewer than in March, and 20 fewer than in April of last year; of these, 4 were registered in Glasgow, and 1 each in Edinburgh, Aberdeen, Paisley, and Perth.

PROPOSED SMALL-POX HOSPITAL FOR EDINBURGH.

A subcommittee of the Public Health Committee of Edinburgh Town Council considered, on May 17th, a communication from the Local Government Board regarding the erection of a small-pox hospital in some isolated part near the city. It was agreed to request that representatives of the Board should meet with the committee to discuss the matter.

MENTAL PATIENTS OF THE EDINBURGH ROYAL INFIRMARY.

At a meeting of the Edinburgh Parish Council held on May 17th an important recommendation was agreed to with reference to the treatment of cases of temporary mental disorder in the Royal Infirmary, and to the application from the managers of that institution for a contribution to the funds of the Infirmary under the Poor Law Act of 1845. The subcommittee of the parish council reported (1) that in its opinion the poor of the parish receive benefit from treatment in the Infirmary or as out-patients to such an extent as would warrant favourable consideration by the parish council of the application from the directors of the Royal Infirmary for a contribution; (2) that a contribution of £150 be made by the council to the Infirmary during the financial year of the council ending May, 1910; and (3) as regards cases of temporary mental disorder considered by the examining medical officer as suitable for treatment and observation in the Infirmary, and sent there at the instance of the Inspector of Poor, the council should agree meantime to pay the Infirmary authorities at the rate of 3s. 6d. a day for each case, the matter to be reconsidered when statistics as to the number of cases sent for treatment during a year became available.

[FROM OUR SPECIAL CORRESPONDENTS.]

TUBERCULOSIS HOMES AT HEALTH RESORTS.

EXCEPTION has been taken by the residents of Howth, Sutton, and Baldoyle, near Dublin, to the recent proposal of the Women's National Health Society in Ireland to open the coastguard station at Sutton as a "health home" for persons in the early stages of consumption.

On May 17th a deputation, consisting of many of the leading residents, was received by Lady Aberdeen, the president of the association.

Mr. Andrew Jameson said that the scheme, if carried out, would be most injurious to Sutton as a summer resort, would depreciate all sorts of property, and deprive owners of the opportunity of letting their houses. A great many holiday makers and an immense number of children spent the summer in Howth. If consumptive patients occupied the coastguard station it would be a really serious source of danger. Professor O'Sullivan had said he hardly believed that any one who regarded tuberculosis as an infectious disease would consider the site as suitable for

a tuberculosis sanatorium, and thought the residents should protest as strongly as possible against a proposal so dangerous. Dr. Earl wrote that he would have less objection to a small-pox hospital near his residence than to a sanatorium for tuberculous diseases.

Lady Aberdeen, in replying, said the association had many purposes to which it wished to apply the various stations. In the first place, they would be called health homes, and she thought that that name would better explain the objects. The very last thing that would be done would be to start any institution that would be deleterious to the health of the residents in any district. The homes in many cases would be only for preventive cases and for persons who were run down and needed rest and good air. A pamphlet had been issued in the United States which showed that an inquiry had been addressed to 77 of the largest sanatoriums, and in 53 per cent. the value of the land had increased, in 35 per cent. there was no change, and in 7 per cent. a more or less marked depreciation. It was quite clear that where a wise policy was adopted a district sanatorium might benefit the community. What the association proposed to do would be of no danger at all to the residents. She wished that the result of the conference would be to dispel panic.

The President of the Royal College of Physicians and the President of the Royal College of Surgeons expressed the view that no risk would be run from the opening of the health homes.

Dr. Aberne, Father Colohan, P.P., approved the proposal.

Lady Aberdeen asked if the deputation would accept an assurance that no cases would be sent there for the present except preventive cases.

Mr. Jameson asked if they could have a guarantee in writing, and Lady Aberdeen then drafted the following statement:

We undertake that for the present no cases will be sent to Sutton suffering from pulmonary tuberculosis, and that the health home will be used only for preventive cases, which have been duly examined and pronounced non-infective by a competent medical authority.

Mr. Jameson, on behalf of the deputation, said they could not accept that guarantee with the words "at present" included.

The deputation then withdrew.

We cannot but regret that this difference of view has arisen, but it is only to be expected that persons with rights should try to preserve them from assault. The movement against tuberculosis will, it is feared, cease to be popular or to be supported by the public, if favourite places of resort are selected for tuberculous health homes. The fears expressed may be—and, we should judge, are—exaggerated; but, considering the immense coast line which Ireland possesses, it would be more politic to choose places not commonly frequented by health and pleasure seekers in large numbers. It is not only in Ireland that this objection is felt, for there are health and pleasure resorts—in Switzerland, for example—which used to be anxious to cater for consumptive patients, but now exclude them.

Victoria.

LUNACY.

THE report of Dr. W. Ernest Jones, Inspector-General of the Insane for the State of Victoria, for the year ended December 31st, 1907, recently received by us, shows that on January 1st of that year there were 4,937 persons certified as insane, and that by the end of the year the numbers had increased to 5,052, or an increase of 115. Of the total numbers at the end of the year, 4,961 were on the books of the seven public asylums, and 91 on the books of the five licensed houses. The proportion of insane to general population at the time of Dr. Jones's report was, he states, 1 in every 249. Victoria has thus a high ratio of insanity, for the ratio in England and Wales in 1907 was 1 in every 282. This would appear, however, to be due to accumulation rather than to increasing occurrence of insanity, for a reference to the table, in which is given a general survey of the statistics since 1891, shows that whilst the total numbers remaining at the end of each

year have undergone progressive increase, the actual numbers of the yearly admissions have not substantially altered in the past decade. The total cases under care during the year 1907 amounted to 5,615, and the average number daily resident 4,571. In his report Dr. Jones deals separately with the State hospitals, the receiving house, and the private licensed houses, and it will be convenient in this abstract to follow his plan.

STATE HOSPITALS.

Admissions.

During the year there were 742 cases in all admitted, of whom 14, however, were statutory readmissions, leaving 728 actual admissions, as compared with 773 for the preceding year. Of the total number, 641 were first and 87 not-first admissions. In 316 the attacks were first attacks within three, and in 94 more within twelve, months of admission; in 111 not-first attacks within twelve months of admission, and in the remainder the attacks were either of more than twelve months' (77) or of unknown duration (19), or of congenital origin (35). They were classified according to the forms of mental disorder into: Mania of all kinds, 142; melancholia of all kinds, 99; senile and secondary dementia, 159; delusional insanity, 126; general paralysis, 42; primary dementia, 37; epileptic insanity, 16; confusional insanity, 11; congenital or infantile defect, 77; and other and rarer forms, 19. The high proportion of secondary and senile dementias in this list is striking. As regards probable causation, alcohol was assigned in 64, or just under 8.8 per cent.; venereal disease in only 15; puberty and the menopause in 17; old age in 63; previous attacks in 86; moral causes in 129; starvation in 10; bodily trauma in 28; and various bodily diseases or disorders in 59. Hereditary influences were ascertained in only 57 and congenital defect in 56.

Discharges, Deaths, etc.

During the year 219 were discharged as recovered, giving a recovery-rate on the admissions of 30.08 per cent., with one exception the lowest recovery-rate since 1891. Also 68 were discharged as relieved, and 16 as not improved. It is to be noted that the general statistics of the State hospitals do not include cases sent to the receiving house and wards and discharged therefrom, therefore the increased use of the reception house accounts to some extent for the low recovery-rate of the State hospitals; but, on the other hand, the medical superintendents of the several State hospitals comment, in their reports, on the unfavourable class of cases received during the year. During the year 323 patients died, giving a death-rate on the average numbers resident of 7.17 per cent. The deaths were due in 56 to cerebro-spinal disease, with only 22 deaths from general paralysis; in 129 to chest diseases, including 45 from pulmonary consumption and 67 from pneumonia; in 53 to abdominal diseases, with 12 deaths from typhoid fever; and in 36 to general diseases, including 19 from senile decay. A troublesome outbreak of typhoid fever occurred at Kew Asylum in April, 1906, spreading some months later to the Idiot Asylum at Kew, and lasting in the main asylum till March, 1908. In the whole epidemic there were 61 cases of undoubted typhoid, occasioning 14 deaths in all. This epidemic was the subject of an investigation by the pathologist, Dr. Mackenzie, whose report is appended to the general report. His inquiries and those of Dr. Hollow resulted in the discovery of one "typhoid carrier" whose stools contained typhoid bacilli nine months after recovery from the fever.

Cost.

The average total weekly cost of maintenance per patient in the State hospitals was 11s. 3½d., or, deducting collections, 9s. 8½d.

LICENSED HOUSES.

At the beginning of the year there were 79 patients on the books of the licensed houses, and at the end of the year there remained 105. During the year 90 were admitted, in 71 of whom the attacks were first attacks. Only 4 were returned as suffering from general paralysis. Only general information is supplied as to the licensed houses, but it is stated that 31 were discharged as recovered, giving a recovery-rate on the admissions of 34.4 per cent. During the year 9 died, including 1 by suicide. The Inspector-General reports favourably upon the management of the licensed houses, but considers

they would be still more useful if they were permitted to admit voluntary boarders.

RECEIVING HOUSE, ROYAL PARK.

The most important event in the treatment of the insane in Victoria in 1907 was the opening of this institution in September. From September 26th to the end of the year 86 cases were admitted, including among them almost all forms of mental disorder. Cases of recent melancholia were the most numerous (19), but there were also 10 cases of recent mania, 6 of general paralysis, 12 of delusional insanity, and 6 of alcoholism. Of the 86 admitted 33 were later transferred to hospitals for the insane, 33 were discharged recovered to their homes, 2 discharged as relieved, 1 as not improved, and at the end of the year 17 remained in the institution. Dr. Jones says that there is every reason to believe that the receiving house is filling a long-felt want, and that probably, as an adjunct to the mental hospital—that is, as the reception ward of the mental hospital—its usefulness will be still greater in the future.

THE MENTAL HOSPITAL.

In 1906 the Cabinet of Victoria decided to permit the diversion from its original purpose as an inebriate retreat of a building close to the receiving house and its conversion into a mental hospital. The building will have accommodation for 120 patients, and in addition to the usual adjuncts it is proposed to equip it with a clinical and pathological laboratory. It has further the advantage of being close to the university and the medical school, and its establishment should prove of great benefit to lunacy in Victoria. Its opening, however, will necessitate several alterations or additions to the lunacy law of Victoria, and these matters were still undecided at the time of the report of the Inspector-General.

Correspondence.

THE BUDGET.

SIR,—Is it not beneath the dignity of the profession to take the ground which many have, to go cap in hand to ask the Chancellor of the Exchequer to grant us concessions in the petrol tax, and to urge each member of the profession to seek the good offices of his member of Parliament to assist us in the matter? It seems to me not only degrading, but that we have no claim to any special abatement. We should face the expenses of our own profession like every other citizen, and should be above asking or accepting doles; but we should have the manliness to fight for our just rights.

It is not in legitimate taxes where the shoe pinches us as a profession. But we do feel and resent the injustice we suffer in being coerced under penalty to give our work to the State as no other members of the community are ever asked to do.

It is not just to demand from us certificates of death gratis; they are required solely for State purposes.

It is unfair to constrain us to notify births without remuneration.

It should not be obligatory on resident or visiting members of the staffs of large or small hospitals to make *post-mortem* examinations and attend the coroners' inquests to give evidence on patients who die in hospital after accidents without receiving any payment. Surely our free services to hospitals should not be burdened by this gratuitous work for the State.

These are a few of the instances in which our generosity is trespassed upon; and it is in such cases where we suffer in dignity and financially. We do not wish, and ought not to seek, concessions; but we ought, one and all, to contend for our rights as members of a noble profession, and as citizens of this great empire. If we honoured ourselves more we should receive more honour in return. Let us cease asking for alms and claim what is our birthright. This is where the British Medical Association should show and use its strong arm. If we are content to accept concessions in taxation for those of us who happen to be sufficiently well off to be able to keep cars, what will the answer be when we claim as our right just payment for work done for the State?—I am, etc.,

Rugby, May 15th.

CLEMENT DUKES.

Sir,—I quite agree with "An M.D. who drives a Carriage," and I also think that medical motorists should be satisfied with the reduction in licenses and not expect it on petrol as well. Some of my medical friends tell me that they can now do their work in half the time and at half the expense of horse-keep—that they have their afternoon free for golf and tennis and their evening for bridge: as for railways they have no use for them however great the distance.

From this it would surely appear that the motor is not used solely as "a means of earning a mere living."—I am, etc.,

May 16th.

"EQUES."

Sir,—The suggestion of Dr. O'Connor¹ is apt to the present time. Friendly societies are exceedingly reluctant to increase the doctor's payment, and sick clubs tumble over each other in devising the lowest possible subscription. If we grant that these payments work out at a remuneration of something less than 1s. a visit or attendance, then any additional cost of medicine is an undue and exorbitant tax to be deducted from whatever profit there may be. The attempt should be made by every club doctor to charge a penny for medicine (a penny is paid for a bottle—we are dealing with poor folks, do not despise details). This is a mode of reasoning that the working man understands, and really the average club member is not so harsh and grasping as their spokesmen lead us to believe. In all probability increased pay in this indirect way would not be greatly objected to after the members became used to it.

The Divisions might here do good work and might advise all the club doctors within their membership. We in the Kensington Division are desirous of knowing the percentage of attendances and of bottles of medicine in club practice in the metropolis, and I shall be glad to hear from any one who has been careful enough to keep his club practice separate in his visiting list.

Dr. O'Connor, it is true, proposes to ask an additional shilling per annum. If some increase be obtained on whatever ground, no doubt it will stay, and the timid counsels of "Club Doctor" are not for a moment to be listened to. It is on the Branches and Divisions and the medical societies throughout the country that the responsibility rests.—I am, etc.,

London, W., May 17th.

GEORGE CRICHTON, M.D.

Sir,—Ten days ago, as Medical Officer of Health for the most thinly-populated and mountainous county of England, I drew the attention of our county members to the fact that, in this county at least, where a high-powered motor is a necessity, and the doctors have great distances to travel, both horizontally and vertically, per patient visited, the petrol duty would be a most serious matter—would, in fact, be a tax on health and life, for the small farmer up in the mountains, miles away from his doctor, is by no means a wealthy man.

Within three days I received from one of our members a letter, in which he says: "The country doctor is to get his petrol untaxed, according to the Budget scheme—the only person so privileged." He is not to have a rebate, for the simple reason that what he uses is to be untaxed.

Few people have any idea of the petrol bill or the tyre account of the country doctor, who motors forty or fifty miles per day, rises 3,000 ft. vertically, consuming his petrol accordingly, or puts his brakes hard on down a gradient of 1 in 8 or 1 in 10 to get down 3,000 ft., and tears his tyres in pieces by so doing. A tyre bill is bad enough to him, with his small receipts and exposure to wild weather, so don't begrudge him his Free Trade petrol!

We must wait till the "Finance Bill" is in print to ascertain exemptions proposed.—I am, etc.,

R. MUSGRAVE CRAVEN,
Medical Officer of Health, Westmorland Combined
Districts.

Kendal, May 15th.

* * * We hope that Dr. Craven's information may prove to be correct, but this cannot apparently be determined until the Finance Bill is published, which will not happen until the resolutions have been passed.

FOREIGN BODY IN THE AIR PASSAGES.

Sir,—The report in the JOURNAL of May 15th, p. 1180, of a fatal case of bronchiectasis due to the unsuspected presence of a foreign body in the left bronchus in a child of 4 years of age, induces me to call attention to the value of the bronchoscope in the investigation of cases of limited bronchiectasis of obscure non-tuberculous origin. If there had been forthcoming in this particular case a history of a tinctack having been inhaled it is probable that the child would eventually have been referred to a laryngologist experienced in the use of the bronchoscope, and from its position no difficulty would have been encountered in its diagnosis and removal.

It is a mistake to imagine that the employment of the bronchoscope should be limited to cases in which there is a history pointing strongly to the fact that a foreign body is present, whether backed up or not by an x-ray examination. That a careful bronchoscopic examination may help to clear up the diagnosis in some cases of limited suppurative bronchiectasis cannot, I think, be doubted, and it is, in my opinion, not only a justifiable but a necessary diagnostic procedure. Those who are familiar with the recorded results of bronchoscopic investigations on the Continent and in America well know that unsuspected causes of bronchiectasis other than foreign bodies have been found by direct endoscopic examination—for example, innocent bronchial tumours, cicatricial formations, and caseous plugs. In limited bronchiectasis, therefore, a routine bronchoscopic examination *per vias naturales* may be expected in the near future to take a recognized place in the diagnosis and treatment of this condition. The passing of the bronchoscope is comparatively easy, even in children, in expert hands, and in my experience patients are none the worse, provided the examination is made with delicacy and caution. Chloroform is, of course, usually necessary in children.

In the case under discussion it is perhaps open to doubt whether the recognition and removal of the foreign body would have effected a cure at the late stage when the child came under the care of Dr. Murray Leslie, but such a method of investigation probably held out the only possible chance for the child.

I am unable personally to claim to have found an *unsuspected* cause in a case of bronchiectasis by endoscopic means, though my experience includes the finding of an unsuspected foreign body by such means in the oesophagus. There are several laryngologists in this country who are skilled bronchoscopists, and it would be interesting to have their experience on the question which I have, I think not inopportunistly, raised.—I am, etc.,

London, W., May 17th.

WILLIAM HILL.

TETANUS OCCURRING AFTER SURGICAL OPERATION.

Sir,—In view of the widespread use of catgut as a ligature material Mr. W. G. Richardson's paper (BRITISH MEDICAL JOURNAL, April 17th, 1909, p. 948) has naturally aroused considerable interest amongst surgeons. While his article is a most careful record of facts and observations he does not venture any definite conclusion as to the real nature of the spasmodic conditions which have supervened after the use of catgut in the cases he has collected.

Unfortunately, the cases published since the appearance of his paper carry us no further, since in those in which a bacteriological examination was made it was inconclusive, while in others no attempt seems to have been made to discover what bacteria were present, although the cases were called tetanus. However, whether or not catgut was to blame in all the cases of so-called tetanus which have been reported, it behoves surgeons who use it as a ligature material to look to the method of sterilization employed. I venture to quote a paragraph from a paper of my own, on Ligatures and Buried Sutures, with special reference to Catgut (*Lancet*, April 20th, 1907), in which it was advocated that animal ligatures should be sealed in glass tubes with xylol and the tubes boiled for half an hour or an hour, or for about twenty minutes on each of two succeeding days, the equivalent temperature being raised to well over 100° C. by the pressure inside the tubes:

There is one condition to be attached to the routine use of catgut, and that is that the surgeon must be certain of its sterilization. For this purpose it is at least desirable that the

¹ BRITISH MEDICAL JOURNAL, May 8th, p. 1155.

process be carried out by some one who can be trusted and is known to the surgeon. Another essential is that the method should be simple, inexpensive, and easily carried out, and that there should be no chance of contamination of the material after it has been sterilized. To fulfil these conditions it is better that the gut should never be interfered with between the time of its sterilization and the time when it is used in an operation. Any method of storage which involves repeated withdrawals from the same stock is objectionable on this account alone. In conducting experiments on the sterilization of animal ligatures I have always considered that those methods which aim at this end by means of chemical antiseptics are inferior to those in which heat is the agent employed. I was convinced that practically all surgeons with an aseptic technique would also prefer a method of sterilization by heat to any chemical disinfection.

—I am, etc.,

Middlesex Hospital, W., May 17th.

ALFRED E. JOHNSON.

EARLY DIAGNOSIS AND TREATMENT OF CANCER OF THE STOMACH.

SIR.—In discussing the operative treatment of cancer of the pyloric end of the stomach Mr. Moynihan says "all the primary glands at least should be taken (these are the lower and upper coronary, right paracardial, suprapyloric, right suprapancreatic, right gastro-epiploic upper and lower, and the retropyloric)." According to him the removal of all these parts is possible, and he has in several cases removed the right suprapancreatic glands by "gauze stripping," without injury to the hepatic artery or the pancreas.

While admitting the possibility of complete removal of all the glands along the lesser curvature and coronary artery and along the greater curvature we do not feel convinced that we can modify the conclusion to which we gave expression in the *Lancet*,² after examining a large number of specimens, that many of the primary glands of the stomach are beyond the effective reach of the surgeon. Many of the right suprapancreatic glands lie under the hepatic artery almost embedded in the upper border of the pancreas.

Moreover, we believe that the list of glands given above does not include all the primary glands. We have already stated that in some of our specimens in which injection was very complete vessels pass from the pyloric end of the stomach directly to glands of the biliary chain lying along the lower part of the common bile duct.

The removal of the primary glands is an advance in gastric surgery founded on recent anatomical research, and though it is desirable that in the operation of partial gastrectomy every attempt should be made to remove as many glands as possible on the lines laid down by Mr. Moynihan, it should be borne in mind that unless the right suprapancreatic glands can be entirely removed, which we doubt, and unless the biliary chain is included in the field of operation, it cannot be supposed that the whole lymphatic area of the pyloric end of the stomach has been excised.—We are, etc.,

J. F. DORSON,

J. KAY JAMIESON.

Leeds, April 28th.

THE COAGULATION TIME OF THE BLOOD.

SIR.—Professor Sabrazès writes that in my article in your issue of April 24th I quote his method as being one of the most accurate. But he has quite mistaken my meaning. I do not think that it can be described in any way as an accurate method, and I only said that the end-point which he and Dr. McGowan adopt is more reliable than that employed in other clinical methods.

In the paper¹ in which I described my method of determining the coagulation time of normal blood, I reviewed the different methods, and among them Professor Sabrazès's and Dr. McGowan's. I referred to all the work which Professor Sabrazès has done on this subject, and showed that both methods, although in other respects different, had in common the adoption of very similar end-points. In my article in the *BRITISH MEDICAL JOURNAL* I therefore did not go over this ground again in detail, but only mentioned Professor Sabrazès's name in connexion with the point in which Dr. McGowan's method resembles his. The two methods are, however, essentially different. It is true that at first I did not think so, and was inclined to believe that McGowan's method was, indeed, rather a

retrogression, because he did not pretend to keep a constant temperature; but that was before I had had any practical experience in working with both of them. I wrote to Professor Sabrazès, and he was so good as to order for me the complete apparatus in its latest form, and in using it I closely followed his directions. I then found, in the first place, that in taking the second drop of blood from the puncture instead of the first drop, as in McGowan's method, he had allowed entrance to a source of considerable error. There is an acceleration of coagulation in the blood following the first drop, and the amount of this acceleration is inconsistent. In the second place, the method of maintaining a constant temperature was so extremely inefficient as to be little better than none at all. It is possible at the expense of a considerable amount of time and trouble to obtain for a short time an approximately constant temperature in the closed box, but the lid has to be removed every half minute in order to test for coagulation. If the room temperature is higher or lower than 18.5° C. there is, of course, an almost immediate equalization of the temperature of the air in this wide shallow box with the room temperature, and this disturbance is only very slowly corrected, when the lid is replaced, by the warm water or ice in the lower compartment of the box, and long before the temperature has returned to the constant the lid must be again removed to ascertain again whether coagulation has occurred. By no device, and I tried many, did I find it possible to maintain anything approaching a constant temperature of 18.5° C. unless the room temperature happened to be 18.5° C. also. Dr. McGowan's method, of course, pays no attention to variations of temperature between 15° C. and 20° C., and for this reason is useless for making comparative observations, but in this respect it is very little inferior to Sabrazès's.

Besides these points there are many other differences between the two methods, some of which are referred to in Professor Sabrazès's letter. For example, he lays stress on the importance of using tubes of exactly equal diameter. Now, McGowan's tubes are not very uniform in this respect, and in testing McGowan's method I thought of this as a possible source of error, but in practice I found that it made no appreciable difference. When two McGowan's tubes taken at random without reference to their diameter were filled from the same drop of blood and both placed together, so that they were under the same conditions, the average difference in fourteen of such double estimations was 25 seconds. When the tubes were specially selected so as to be as different in their diameter as possible, the average difference of thirteen estimations was also 25 seconds. The average difference of fifty-six estimations when tubes of equal diameter were obtained by using halves of the same tube was 29 seconds.

Another important point of difference is that in Sabrazès's method short columns of blood are used, whereas in McGowan's a column of about 4 in. long is employed. Professor Sabrazès says that with a short column you avoid "the error caused by the unequal repartition of fibrin in long tubes." Does he mean by this that fibrin in a tube of 1 mm. diameter can in the half-minute or so in which it may be present before its discovery alter its position to any appreciable extent under the action of gravity? It would, to say the least of it, appear to be extremely improbable that it does. I should like to know what evidence he has to show that there is any such "unequal repartition of fibrin" in blood under these conditions. On the other hand, I can show that short columns of blood are sure to lead to error. In the paper above referred to, in discussing the action of different foreign bodies in regard to their effect on the coagulation time, I have shown that air has about twice as great a power of accelerating coagulation as glass; and this has been fully borne out by my experience in using McGowan's tubes. When the column of blood is interrupted by bubbles of air, the blood near the air bubbles is always found to have coagulated first. For this reason the first and last quarter of an inch of the blood column in a properly-filled McGowan's tube must not be tested for coagulation, as this is very apt to give a fallacious result. But this is just the condition under which one works with the short column of blood in Sabrazès's method, so that this comes to be a very important difference between the two methods.

¹ *BRITISH MEDICAL JOURNAL*, April 3rd, 1902.

² Lymphatic System of the Stomach, *Lancet*, April 20th, 1902.

³ *Quart. Journ. of Exper. Physiol.*, Nov., 1903.

When Professor Sabrazès says that no method can be absolutely accurate as regards the maintenance of a constant temperature because of the differences in the body temperature of the persons from whom the blood is taken, he is no doubt, strictly speaking, quite right, although it is more a theoretical than a practical objection, for I have never found fever in itself to have any appreciable effect on the coagulation time of the blood *in vitro*; but when he goes on to say that such differences as may exist between the physical properties of blood from different people are sufficient to alter noticeably the rate at which the temperature of the blood comes into equilibrium with the temperature of its surroundings, he is making a surprising statement, which, so far as I know, is entirely unsupported by any experimental proof.

The unreliability of his method is clearly shown by the account of the work done with it by Genenil¹ under Professor Sabrazès's own direction. Many of the results appear to have been obtained by Professor Sabrazès himself. Fifty-eight observations were made on patients. They are extremely variable, not only in different but also in cases of the same disease. Times of 3 minutes, 3½ minutes, and 4½ minutes are given, while at the other extreme there are times of 15 minutes and 17 minutes, and all degrees between these two limits are represented, although most are between 7 and 12 minutes. I exclude two cases of hæmophilia in which times of 30 and 35 minutes are recorded. Some cases of malignant disease are shown to have times varying from 3 to 10 minutes, in three cases of amenorrhoea the times were 9½, 12½, and 15 minutes, and so on, so that when an attempt is made to draw general conclusions, the results are so conflicting that it is obvious that they have no firm basis. As a matter of fact, the variations they record are practically, without exception, due to experimental errors, for I have found with my modification of McGowan's method that the coagulation time is practically normal in patients suffering from such conditions as their list is made up of; the only exceptions which I have so far found have been cases of hæmophilia or those cases in which there was reason to believe that a condition of septicæmia was present or had recently been present.

For these reasons I think that Professor Sabrazès is not justified in recommending his method as not only simple but also exact and accurate. It is certainly not accurate. Nor should he say that Dr. McGowan or I have "borrowed" his method. Dr. McGowan developed his method entirely independently; he most certainly did not in any way or in any detail derive it from Professor Sabrazès. And since I, in modifying McGowan's method, specially mentioned Professor Sabrazès's in relation to the only point in which there is any resemblance between the two methods, and refer to a paper in which I discuss his work, I think I have done fully as much in the way of acknowledging his connexion with the subject as could reasonably be expected.—I am, etc.,

Berlin, May 9th.

T. ADDIS.

RESISTANCE TO PUERPERAL INFECTION.

SIR,—Dr. Chevers asks a most interesting question (May 8th, p. 1154), and one which must have occurred more than once to practically every physician who practises obstetrics, but more especially to those whose lot it is to practise the art among the lower sections of our population.

In my experience it is almost usual in, for example, a colliery district, for the parturient woman to don her dirtiest working clothes at the onset of labour, and to pile around her on the bed the filthiest and most suspicious rags which the dwelling can provide. Among these she may lie for days, the warmth of the bed no doubt favouring considerably the decomposition of blood and lochia and the growth of any bacteria which may happen to be present.

With Dr. Chevers's explanation, however, I do not agree, and my own is as follows: Roughly, the population may be divided into those whose habits are cleanly and those whose habits are not. The latter class is constantly exposed to the risks of puerperal sepsis, and, as a consequence, suffer more from its ravages. As time goes on, however, the very susceptible among them become weeded

out, simply because they die and leave no offspring, or only a limited number; the less susceptible or, in other words, the more immune in virtue of the natural immunity they happen to possess, thrive and rear families to which they bequeath this very useful characteristic. It is seen, then, that among the dirty classes the more or less immune (to puerperal fever) thrive; the more or less susceptible die out. Consequently, in time immunity to puerperal fever becomes to a greater or lesser extent a feature of the dirtier classes; in other words, dirty habits and immunity to puerperal fever become correlated.

In the case of the class guilty of considering cleanliness a virtue, the risks of puerperal sepsis are by instinct reduced to a minimum, and so is the ultimate immunity which the class as a whole acquires against the disease. This explanation, which shows the phenomenon to be one of natural selection or, to use Herbert Spencer's phrase, of the survival of the fittest, also throws light on the fact that, while puerperal fever very seldom occurs in lying-in hospital practice, a certain proportion of cases still occur in private practice, owing to the fact that the hospital patient is more often than not a member of the lower and therefore more generally dirty classes.—I am, etc.,

Ullapool, May 11th.

A. R. GUNN, M.B.

UNQUALIFIED MEDICAL PRACTICE.

SIR,—In your issue of May 15th you publish a copy of the circular addressed by the Local Government Board to medical officers of health, inquiring as to the evil effects of the practice of medicine and surgery by unqualified persons; and a footnote is added giving the reply of one of your correspondents, to the effect that there is no unqualified practice in his district except that of chemists; this reply is also commented on in your editorial on page 1200 of the same issue.

Unqualified medical practice is indefensible in any one, but your correspondent in imputing such to a body of scientific men like pharmacists has no ground for so doing except the delinquencies of a few; and he has overlooked a much more serious and at the same time a universal form of unqualified practice, which not only makes a serious inroad on the rights of physicians and pharmacists alike, but is a great and growing danger to the public health. I refer to the sale of proprietary and "patent" medicines, the manufacturers of which, as a rule, are neither doctors nor chemists, and thus possess no qualification whatever, except the qualification of commercial enterprise. A pharmacist, if he has not the medical qualification, has at least that of understanding the drugs he handles, their actions and their doses, and in many cases he also knows not a little about the body into which they are put, and it is often necessary for him to give some advice, generally in the form of warning, as to the use of drugs. Further, it ought to be remembered that the public will never be taught to go to a doctor for every slight ailment, any more than they will be induced to call in a carpenter for every picture that requires hanging; but there are very few chemists, indeed, who are so foolish as to abuse their knowledge or trespass on the domain of the doctor, strong though the temptation is in districts where doctors dispense their own medicine.

But the patent medicine manufacturer has neither diffidence nor scruple. His object is to extort money from the public, and he does so most successfully for himself, though often dangerously for them. His sway is not confined to a suburb or town, but is world-wide; he ingratiates himself, through advertisements, with a simple public before either doctor can advise or pharmacist can warn, and his appeals are generally couched in terms that cast untrue reflections on physicians and pharmacists alike, for these are too honest and too well-informed to serve his purpose.

If the Local Government Board, genuinely actuated as they are by a desire for the public weal, intend to put down unqualified practice, they should start at the beginning, and take steps to end this crying evil.—I am, etc.,

May 17th.

PHARMACOS.

RURAL DISTRICT NURSING ASSOCIATIONS.

SIR,—When the Midwives Act came into force my midwifery practice fell off considerably. I was frequently

¹ Méthodes pour déterminer le début de la coagulation du sang. Bordeaux, 1906.

called to difficult cases by midwives—some were difficult naturally, others through ignorance or want of skill. I used to go, give my services, and not get paid in more than one case in three. Result, midwifery very unsatisfactory, three deaths, several women permanently injured.

I then informed every midwife, including the nurse employed by the "county lady," that in two months from date I would only attend cases I was engaged for in the ordinary way, and would go to no case of theirs, however urgent or difficult; this was in order that the nurses could explain to the women my decision. They all practically told me if I would not go some one else would. They continued sending; I went until the time was expired; the next case I refused, and I continued to refuse. I was abused on all sides, but still kept to my decision. The result was that in 1908 I was not sent for except where previously engaged. I attended 121 cases, have been paid for 95 of them, and will be paid for most of the others. There have been no deaths.

I am a member of a union, and advocated my way of dealing with unruly midwives and nurses. Most of the members practically told me it was most unprofessional to act in such a manner, and asked me what would the public say if a patient died. One gentleman told me my duty was to save life, allay pain, and take what payment I could get after the work was done. After sixteen months' strict adherence to the above rules, I am glad to say my practice all round has not suffered, and several working men have told me they are glad I acted as I did, as they can see now that it has been for their benefit to have skilled attention for their wives.

A lawyer is a gentleman in private, a business man in his office. A clergyman is a gentleman in private, but a good business man in public. Is a doctor to be a gentleman in private and a fool in his business?—I am, etc.,

May 11th.

ANOTHER G. P.

THE LATE SIR WILLIAM GAIRDNER.

Sir,—In response to the wishes of Lady Gairdner and her family, I have undertaken to edit the medical and scientific papers and articles of the late Sir William Tennant Gairdner, and to preface the collection with a biography.

In order to render the work as worthy as possible of the memory of the late professor, I am desirous of enlisting the sympathy and help of his friends. I venture, therefore, to request through your columns that any one who has in his possession any letters or other literary remains of Sir William Gairdner will be so kind as to communicate with me.—I am, etc.,

G. A. GIBSON, M.D.

5, Drumsheugh Gardens, Edinburgh, May 12th.

LOCAL ANAESTHETICS RECOMMENDED AS SUBSTITUTES FOR COCAINE.

Sir,—Referring to the recent report to the Therapeutic Committee on "The Local Anaesthetics Recommended as Substitutes for Cocaine" by Dr. Le Brocq, which was published in the BRITISH MEDICAL JOURNAL of March 27th, may we be allowed to point out that the material used by the investigator in demonstrating relative toxicity was strictly confined to rabbits, mice, and frogs? Thus the conclusion arrived at in the report that alpin is more toxic than cocaine only means that it is more toxic to these animals. As a matter of fact, had Dr. Le Brocq carried out his experiments on cats and dogs he would have obtained quite different results. The average lethal dose of cocaine in cats was found by Dr. Impens to be 0.04 gram per kilo body weight, and that of alpin 0.06. On the human subject also, clinical experience has proved that alpin is much less toxic than cocaine.—I am, etc.,

London, E.C.

THE BAYER CO. LTD.

DR. JOHN HORNE, of Scarborough, who graduated M.D. in the University of Edinburgh in 1859, is about to present in perpetual trust a building on a freehold site in Scarborough, containing eight homes for aged and deserving persons who, while they possess a small income, are yet not in a position to pay house rent. Each home consists of a combined kitchen and sitting room, a bedroom, and a combined scullery and pantry. The building, which has a verandah, is of brick with stone dressings, of the Tudor style. It will be unendowed, but Dr. Horne has provided a fund for the payment of the fire insurance, upkeep, and water rate.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following degrees were conferred on May 13th:

M.B., B.C.—B. H. Palmer, Pemb.; J. R. C. Canney, Christ's.
M.B.—C. H. Treadgold, Clu.

UNIVERSITY OF LONDON.

GUY'S HOSPITAL MEDICAL SCHOOL.

Mr. R. A. CHISOLM has been appointed Greville Research Student for research in connexion with the subject of cancer.

VICTORIA UNIVERSITY OF MANCHESTER.

The Winter Session.

THE Chancellor of the University, Viscount Morley of Blackburn, has consented to open the new session on October 5th, and to deliver an address.

Dean of the Medical Faculty.

Professor Stirling has been reappointed Dean of the Medical School and of the Faculty of Medicine.

Votes of Condolence.

At a meeting of the Council, held last week, resolutions were passed expressing the profound regret of the Council at the deaths of Professor Gamgee, formerly Professor of Physiology at the Owens College; of Dr. Lang, Principal and Vice-Chancellor of the University of Aberdeen; and of Mr. T. F. Byrne, formerly Lecturer in Common Law in the Manchester University.

Memorial Tablet.

A medallion of the late John Strachan, M.A., LL.D., formerly Professor of Greek in the University, has been presented to the university by the subscribers to the Strachan memorial fund, and it is proposed to unveil it on Tuesday, May 25th.

UNIVERSITY OF BIRMINGHAM.

Opening of New Buildings.

AN intimation has been received that the King and Queen will open the new buildings of the University of Birmingham on Wednesday, July 7th. A site of 27 acres was presented to the university by Lord Calthorpe, who subsequently gave 20 additional acres for a recreation ground. The total cost of the buildings will be £400,000, and with the equipment, the expenditure will exceed half a million. Of the £200,000 received in response to Mr. Joseph Chamberlain's appeal, only about £300,000 has been available to meet the outlay on the buildings and site, and the council now appeals for another quarter of a million to enable it to provide for future developments and open the buildings free of debt; of this sum about £75,000 has been received.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held at the College on May 13th, the President, Sir R. Douglas Powell, Bart., in the chair.

Fellowship.

The members elected at the preceding Comitia, were admitted Fellows of the College (see p. 1156.)

Licence.

The licence of the College was granted to Mark Bates and Thomas Benjamin Dixon.

Resignation of Dr. E. Liveing.

A letter was read from Dr. E. Liveing, resigning his office of registrar and the membership of the Committee of Management, both to take effect at the end of the collegiate year in July next.

The President spoke in eloquent terms of the services of Dr. Liveing, and regretted that the purport of his letter left the College no option but to accept his resignations.

Sir Wm. Church then moved:

That the College receives with much regret the resignation of Dr. Liveing of the office of registrar, and in accepting his resignation takes the opportunity of recording on its minutes the faithful and efficient manner in which he has for so many years carried out the duties of his office, his constant courtesy to the Fellows, and his universal watchfulness over the interests and dignity of the College.

This was seconded by Dr. Norman Moore, and carried by acclamation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE COMING COUNCIL ELECTIONS.

THE Council is at present constituted as follows:

President.

Mr. H. Morris; C, (1) 1895 (substitute), (2) 1898, (3) 1906.

Vice-Presidents.

Sir W. Watson Cheyne, Bart.; C, (1) 1897 (substitute), (2) 1901.
Mr. Pearce Gould; C, (1) 1900, (2) 1908.

Other Members of Council.

Mr. Mayo Robson; C. (1) 1893, (2) 1901.
 Mr. Butlin; C. (1) 1895, (2) 1903.
 Mr. Edmund Owen; C. (1) 1897, (2) 1905.
 Mr. Rickman J. Godlee; C. (1) 1897, (2) 1905.
 Mr. F. Richardson Cross; C. (1) 1898, (2) 1906.
 Mr. R. Clement Lucas; C. 1901.
 Mr. J. H. Morgan, C.V.O.; C. 1902.
 Mr. H. H. Cluston; C. 1902.
 Mr. C. W. Mansell Moullin; C. (1) 1902 (substitute), (2) 1907.
 Mr. Clinton Dent; C. 1903.
 Mr. G. H. Makins, C.B.; C. 1903.
 Mr. F. S. Eve; C. (1) 1904 (substitute), (2) 1907 (substitute for Sir J. Tweedy till 1912).
 Mr. A. A. Bowlby, C.M.G.; C. 1904.
 Mr. G. Barling; C. 1904.
 Mr. C. H. Golding-Bird; C. 1905.
 Mr. G. A. Wright; C. 1905.
 Mr. W. Bruce Clarke; C. 1906.
 Mr. Charters J. Symonds; C. 1907.
 Mr. W. F. Haslam; C. 1908.
 Mr. C. B. Lockwood; C. 1908 (substitute for Howard Marsh until 1910).
 Mr. W. Arbutnot Lane; C. 1908.

The following list shows the proportional representation of metropolitan medical schools and the provinces:

St. Bartholomew's	...	4
Charing Cross...	...	1
Guy's	...	4
King's College	...	1
London	...	2
Middlesex	...	2
St. George's	...	1
St. Mary's	...	1
St. Thomas's	...	2
University College	...	1

Total number attached to London schools	...	19
London member unattached to any hospital	...	1
Provincial members (Birmingham 2, Bristol 1, Manchester 1)	...	4
Total	...	24

Having been elected or re-elected in 1901, Sir Watson Cheyne, Mr. Mayo Robson, and Mr. Clement Lucas retire in July, 1909.

An ordinary Council was held on May 13th, Mr. Henry Morris, President, in the chair.

Begrudge Studentship.

Mr. J. R. D. Webb (undergraduate of Liverpool University), having obtained the highest marks, was awarded this studentship for three years. This studentship, of the annual value of £20, is awarded to the candidate obtaining the highest number of marks in the anatomical part of the second examination of the Conjoint Examining Board in England.

The late Mr. C. G. Wheelhouse.

The following resolution was adopted by the Council:

That the Council hereby express their deep regret at the death of Mr. C. G. Wheelhouse, whom they highly esteemed as an able surgeon, keenly interested in all matters relating to surgical education and the advancement of surgical science, and whose services to the profession and to the College they remember with grateful appreciation. That the Council desire also to record their warm regard for the excellent personal qualities which won for Mr. Wheelhouse the friendship of all who knew him and to convey their sincere sympathy to Mrs. Wheelhouse and her daughters in their bereavement.

Diploma of Member.

Diplomas were granted to ninety-one candidates found qualified at the recent examination.

Licence in Dental Surgery.

Diplomas were granted to thirty candidates found qualified at the recent examination.

Courts of Examiners.

Mr. C. A. Ballance was elected a member of the Court in the place of Mr. A. P. Gould, recently retired. The President stated that the vacancy on the Board of Examiners in Dental Surgery, occasioned by the retirement of Mr. Pearce Gould from the Court of Examiners, would be filled up at the next meeting of the Council.

Gift to the College.

A work in bronze and marble by Alfred Gilbert, M.V.O., entitled *Mors janua vitae*, offered by Mrs. Macloghlin, was accepted by the Council, with its best thanks.

CONJOINT BOARD IN ENGLAND.

At a meeting of the Comitia of the Royal College of Physicians on April 29th, and of the Council of the Royal College of Surgeons on May 13th, Diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the following candidates:

A. Abrahams, H. W. L. Allott, M. A. Ansari, R. R. Armstrong, J. L. Atkinson, K. J. Aveling, M. Bates, B. F. Bartlett, P. B.

Bharucha, H. E. Blossome, T. L. Bomford, W. F. Bowen, H. Bowring, E. C. Bradshaw, T. F. Brown, W. R. Butler, F. G. Caley, F. G. Cavston, H. D. Clapham, A. J. Clark, J. P. Clarke, R. Comyn, R. B. Dawson, C. Deutzer, J. R. Dick, T. B. Dixon, J. R. B. Dobson, M. Donaldson, A. W. Duncan, G. H. Dunn, L. W. Evans, T. Evans, P. C. Field, H. W. Gabe, E. B. Garrard, P. A. Gilroy, C. Gouldsborough, G. A. Greaves, H. S. Hall, D. J. Harries, T. Harrison, H. Hudson, E. P. L. Hughes, R. H. Hutchinson, V. P. Hutchinson, R. S. Ingersoll, R. P. Jones, C. F. V. Keble, L. H. Khan, H. G. Kilner, S. J. Lee, A. S. MacNalty, R. H. Maxwell, J. S. Milligan, H. E. H. Mitchell, E. B. Morley, H. R. Moxon, N. R. Naik, F. C. Nichols, R. D. O'Leary, D. G. S. R. Oxley, G. F. Page, R. Pearce, L. B. Perry, R. A. Rankine, A. A. Rees, E. D. W. Reid, A. Rhodes, A. D. Rope, F. A. Roper, A. J. Ryle, F. F. Saldanha, N. G. H. Salmon, A. G. Schlenburg, C. F. Searle, N. S. Shenstone, S. Shephard, H. G. Smith, R. R. Smith, E. R. Stone, T. W. R. Stode, W. F. Sutcliffe, H. L. Tasker, H. A. Treadgold, R. J. Vernon, D. Vainwright, G. Valdo, G. R. Ward, L. M. Webber, M. W. E. Wiedegren, W. G. Wince, R. N. Woodsend, T. S. Wright.

* M.R.C.S. granted on April 1st. † L.R.C.P. granted on May 13th.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examinations indicated:

FINAL PROFESSIONAL.—B. G. S. Belas, F. H. Gleeson, H. G. Massy-Miles, B. Power, E. Smith, G. C. Sneyd, C. H. Stringer, B. Wallace, J. McG. Williams.
 D.P.H.—W. W. Brovne, Captain R.A.M.C.; R. F. O'T. Dickinson, Lieutenant R.A.M.C.; B. D. Gibson, D. J. O'Connor, N. D. Walker, Captain R.A.M.C.

* With honours.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

DISTRICT NURSES AND MEDICAL MEN.

We have received a complaint from a member resident in Scotland with regard to the action of a district nurse, who, as far as we can gather from our correspondent's letter, is not working under Queen Victoria's Jubilee Institute for Nurses, or under rules approved by it. The complaint is that the nurse attends cases of illness, as well as confinements, without the supervision of a medical man. He also makes a complaint against a neighbouring practitioner who, in cases of difficulty—we presume he refers more especially to confinements—has been asked to assist the nurse. The nurse is fully trained, and we also presume, certificated. Our correspondent asks: (1) Whether the practitioner referred to is in order in attending confinements where the nurse fails; he also asks whether under the circumstances the nurse does not act as an unqualified practitioner? (2) Is the doctor in order in attending my cases at the call of the nurse? (3) Am I in order in attending one of my own patients who had been under the care of the nurse? (4) Am I in order in granting a death certificate if the patient above referred to dies? (5) Is the nurse in order? (6) Can anything be done to prevent the nurse practising and being paid by subscription, or can anything be done to stop prescribing chemists and chemists who prescribe one's own mixtures?

* (1) The nurse would fail in her duty if she did not call in skilled assistance. Our correspondent must know that in most towns and villages there are nurses and midwives who do a large practice in midwifery without a medical practitioner being present. If our correspondent will refer to the BRITISH MEDICAL JOURNAL of April 3rd, p. 852, he will see the suggested rules for district nurses under the Queen Victoria's Jubilee Institute. Rule 9 reads as follows:

9. In all cases of general sick nursing the attendance of the nurse must be sanctioned by the medical officer, it being understood that her attendance on such cases does not interfere with her engagements to lying-in women. When she has anything to communicate to the doctor she shall do so in writing, and it is hoped the doctor will do the same to avoid leaving verbal messages with patients or their friends.

The nurse may attend a patient on application or in emergency, but must not continue to visit without a medical man being informed. Should the nurse advise the patient to have a doctor and the patient refuse, the nurse may no longer attend this patient except in case of urgency. She must in any case report the matter to her Secretary.

(2) This, if the facts are correctly stated, would be a breach of professional etiquette. (3) Certainly. (4) Yes, if our correspondent is satisfied as to the cause of death. (5) We do not understand what this refers to. (6) As most, if not all, district nurses are paid by subscriptions collected in the neighbourhood, we can hardly see how this point can affect the complaints our correspondent brings against the nurse.

We would suggest that he should see the principal subscribers and endeavour to get them to form a committee, of which he should be a member, and draw up a set of rules for the guidance of the nurse. The Medico-Political Committee has the matter of rules for district nurses in hand, and is to have a conference with the Committee of Queen Victoria's Jubilee Institute in connexion with the matter. The latter part of query No. 6 refers to a subject too wide for discussion here.

MONOPOLY RIGHTS IN PRACTICE.

DISGUSTED writes that a neighbouring practitioner who practises in an unopposed village six miles from his house, where our correspondent has also an unopposed practice, has opened a surgery in our correspondent's village and dispenses medicine for our correspondent's patients on his own account. Asked to explain what was meant by dispensing medicine "on his own account," our correspondent replies that "wherever a man opens a surgery he is bound to take a certain proportion of patients away from the resident doctor, and his object in writing was to ask whether a man who has an unopposed practice can with any decency open a surgery in his opponent's unopposed practice six miles away, and how this is to be looked upon by members of our profession."

* * No one can claim an absolute monopoly of the area within which he resides, and although it may be regrettable that competition should cause ill-feeling, it is impossible to lay down any hard-and-fast ethical rules which can prevent it.

GRATIS ATTENDANCE ON THE FAMILIES OF MEDICAL MEN.

X. writes: A retired medical man calls in a neighbouring practitioner to see his wife, who is suffering from influenza. She is attended for about a fortnight, and a bill is sent in, charging at the rate of 10s. 6d. a visit. X. is not well off, having an income of about £300 a year, and when in practice made it a rule never to charge a fee to a brother practitioner. He asks what he should do.

* * There is no absolute rule that medical practitioners should not charge one another for their services, but it is a general custom. Payment should always be tendered, although, in our opinion, in most instances it should be refused. We think where there is no friendly relation already existing between the practitioners, if gratis treatment is expected it should be asked for in the first instance. In the present case our correspondent might write a courteous letter explaining his circumstances and asking for a reduction in the amount of the bill.

Medico-Legal.

TRANSFER OF APPOINTMENTS.

"5779" writes that he has recently bought a practice, and that certain appointments were mentioned in a letter during the negotiations as transferable. That letter has been lost, and the vendor says that he could not guarantee an appointment any more than he could a patient. Our correspondent asks whether he would be justified in making a deduction from the purchase money as a set-off against the loss of appointments.

* * It is very usual in the sale of a practice for one of the conditions of sale to be a return of a sum of money equal to the annual income derived from any appointment that the vendor may fail to get transferred. If there is no special agreement to this effect the buyer is not entitled to make any deduction.

At the meeting of the Zoological Society of London on May 11th, Mr. R. H. Burne, M.A., F.Z.S., exhibited a series of specimens, from the Museum of the Royal College of Surgeons of England, of adaptive structures for the respiration of air in some aquatic invertebrates and tropical fresh-water fishes.

A NEUROLOGICAL institute has recently been founded in New York for the treatment of nervous and mental diseases both curable and incurable. The institute comprises also a clinic for the study of nervous diseases, and the training of special nurses in the care of persons suffering such affections. The institute owes its foundation mainly to the efforts of Dr. Joseph Collins and Dr. Joseph Fraenkel, and more than £20,000 has already been subscribed. It is proposed to establish a sanatorium for convalescents in connexion with the institute.

Obituary.

PERCY BOULTON, M.D. EDIN., M.R.C.P. LOND.,
L.R.C.S. EDIN., L.M.

CONSULTING PHYSICIAN, SAMARITAN FREE HOSPITAL FOR WOMEN.

This obstetrician, so well known as one of the most active promoters of the associations for the proper education, examination, and registration of midwives which have developed during the past thirty years, died on May 15th at his town residence, Seymour Street, after a long and trying illness, in his 68th year.

Percy Boulton was born at Beverley on July 9th, 1841, and received his education in that town. He belonged to a medical family, his father, Dr. W. G. Boulton, being a practitioner in Beverley, and his brother succeeded the father and continued in the practice until his death several years ago. Percy was an athlete in his youth, and distinguished himself as a runner, and until his recent illness remained robust all through his career.

He studied medicine at the University of Edinburgh, and after qualification set up in practice at Worksop, Notts, but soon afterwards settled in London, where he assisted Dr. Tanner in his private practice. In 1871 he was elected Physician to Out-patients at the Samaritan Free Hospital, and in 1880 full Physician; he retired in 1900. For practical work he is chiefly remembered as the advocate of the purse-string suture in perineorrhaphy, which method he extensively practised at the hospital; but he was mainly distinguished in his hospital career as a loyal colleague and an able chairman, and he greatly contributed to the prosperity of the hospital by pleading its cause before wealthy and distinguished patients.

Dr. Boulton was a very active Fellow of the Obstetrical Society of London. He joined it in 1866, and, although he took but little part in the reading and discussing of papers and the exhibition of specimens, he was an energetic member of the council, working hard in the committees and subcommittees. He held the office of Chairman of the Board for the Examination of Midwives from 1897 to 1900; altogether, he was Examiner for eleven years on that board, which dissolved itself when the Midwives Act became law. Boulton's public spirit and zeal was made specially manifest when, towards the end of the Eighties, the old Berners Street societies left that thoroughfare for their present home in Hanover Square. He took upon himself the greater part of the weight of responsibility for the complicated administrative and legal business involved in the change of residence simultaneously with the maintenance of the relations of the Obstetrical with the Royal Medical and Chirurgical Society, which, as at the old address, remained its landlord. By 1890 the old Berners Street societies, the Pathological and Clinical, as well as the Obstetrical, were lodged in Hanover Square under the wing of the larger and older chartered society, an arrangement which stood for seventeen years, until, in 1907, they, taking up several other similar associations, fused into the Royal Society of Medicine. It was greatly owing to Boulton's good management that the change was managed with little or no inconvenience, so that the old relations remained satisfactory for so many years, until circumstances rendered another change imperative.

Dr. Boulton was as active in promoting legislation for the legal registration of women systematically trained, duly examined, and found fit and proper persons to attend labours, as he had been in guarding the interests of the Obstetrical Society in times of change, when bad management might have caused the Fellows trouble and expense. He acted not as a teacher of obstetrics or as a scientific authority, but rather as a physician admired and respected in influential circles, and by his tact he put before our legislators the state of the case—that is to say, the need for the legal qualification of midwives—in a way thoroughly comprehensible to them. As in the case of the Obstetrical Society, he took an infinite amount of pains, leaving nothing undone that had to be done, and for that he earned the thanks of the present generation of obstetrical teachers who actively worked with him, never relaxing their efforts until the Act became law.

Boulton wrote but little; his most important gynaecological work was quoted in textbooks and formed the subject of a monograph prepared by himself and published

in the thirty-second volume of the *Transactions of the Obstetrical Society*. He also edited the fourth edition of *Tanner's Index of Diseases*, and for six years took upon himself the arduous duties of editor of the *Transactions of the Society* which he served so faithfully.

Dr. Boulton was twice married but had no children.

DR. CHARLES KENNEDY, of Edinburgh, died with startling suddenness early in the morning of Monday, May 17th. He was apparently in his usual state of health on Sunday, and soon after midnight he left his house to visit a patient. He had only gone a yard or two from his door when he died. Born fifty years ago, the son of David Kennedy, the famous Scottish vocalist, he, like many members of his family, had inherited the musical talent of his father, and at the various medical dinners he was always good for two or three excellent songs. He was educated in the University of Edinburgh, took the degrees of M.B., C.M., in 1881, and the degree of M.D. in 1885, when he was awarded a gold medal for his thesis. He had a considerable family practice in the south side of Edinburgh, and was esteemed both by his professional brethren and the public. On May 15th, he was elected Chairman of the South Edinburgh Division of the British Medical Association. He was also a prominent member of the Edinburgh and Leith Medical Practitioners' Association, and a popular member of the Pen and Pencil Club. He had been a Freemason for many years. He leaves a widow and three sons, one of whom is now a student of medicine at Edinburgh University.

OLD St. Mary's men will hear with regret of the sudden death, at the early age of 34, of Dr. WILLIAM FERRIS, who was holding the post of Second Assistant Medical Officer to the Middlesex Asylum, Wandsworth. He was the son of the late William Edward Stiles Ferris, of Donnington Square, Newbury, Berks, and grandson of the late William Ferris, of Milton Manor, Pewsey, Wilts. William Ferris started his medical career at St. Mary's Hospital in 1893. After obtaining the M.R.C.S. Eng., L.R.C.P. Lond., and M.B., B.S. Lond., he was appointed Assistant Medical Officer at the Greenwich Infirmary, and whilst there took the D.P.H. In 1902 he was appointed an Assistant Medical Officer to the Middlesex Asylum, Wandsworth. In 1904 he obtained the M.D. Lond., being the first candidate to take that degree in Psychological Medicine. He was a great favourite with all with whom he came in contact, and was especially beloved by patients and colleagues. His keenness for detail and his methodical ways made many a difficult task appear simple, and he kept himself thoroughly up to date in the modern treatment of the insane. He was good at all sorts of games, especially at football, which he continued to play up to as late as last season. His sudden death, on May 15th, from an attack of double pneumonia, after only five days' illness, will come as a shock to many.

We regret to record the death of JOHN HODGSON, M.B. Lond., M.R.C.S., L.S.A., formerly of Oldham. Dr. Hodgson was the son of a minister of the Congregational Church. His medical studies were conducted at the Owens College and the Manchester Royal Infirmary, where he held the post of house-physician. Later he acted as medical officer at the Barnes Convalescent Hospital, Cheadle. He commenced practice in Oldham, and was appointed assistant surgeon to the Oldham Infirmary, and in 1899 became Honorary Acting Surgeon. He also held the post of medical officer to the Oldham School Board. He was the first Honorary Secretary of the Oldham Medical Society; he occupied the position for fifteen years, and the prosperity of the society was largely due to the enthusiasm with which he discharged the duties of the office. Failing health compelled Dr. Hodgson in 1905 to resign his position as honorary surgeon to the Oldham Infirmary and to give up practice. He first went to West Kirby and afterwards to Bowdon, and his health greatly improved. About two months before his death, he was appointed medical officer to the Southport Council Schools. He, however, had only held that post about three weeks, when his health broke down, and he died after about a fortnight's illness at his home in Bowdon. He leaves a wife and two daughters to mourn his loss. Dr. Hodgson was universally respected by all with whom he came into contact.

The Services.

ROYAL NAVY MEDICAL SERVICE.

AT the entrance examination for Surgeons in the Royal Navy, completed on May 14th, 32 candidates presented themselves for 15 vacancies. Two gentlemen withdrew, 8 were rejected for physical defects, and of the remaining 22, 18 obtained qualifying marks.

The following is the list of successful candidates:

Name.	Qualifications.	Medical School.	Marks.
Hole, K. H.	M.B., B.S. Lond., L.R.C.P., M.R.C.S.	Guy's Hospital.	2,151
Syms, G. F.	L.R.C.P., M.R.C.S.	Guy's Hospital.	1,965
Sanders, A. A.	M.B., Ch.B. Birm.	Queen's Hospital, Birmingham	1,933
Fitzgerald, M. P.	M.B., B.Ch. R.U.I.	Queen's College, Cork	1,927
Hadwen, J.	M.B., B.S., B.Sc. Lond., L.R.C.P., M.R.C.S.	St. Bartholomew's Hospital	1,914
Briggs, H. F.	M.B., Ch.B. Edin.	Edinburgh University	1,900
Jackson, G. A.	M.B., B.Ch., B.A.O.	Dublin University	1,739
Miller, W.	M.D., Ch.B. Glasg.	Glasgow University	1,710
Orwin, J. S.	M.B., Ch.B. Edin.	Edinburgh University	1,685
Barrett, J.	M.B., B.Ch., B.A.O. R.U.I.	Catholic University, Dublin	1,645
Nichols, H. W.	L.R.C.P., M.R.C.S.	Middlesex Hospital	1,638
Roberts, R. P. M.	L.R.C.P., M.R.C.S.	Guy's Hospital	1,505
Malcolm, M. G.	M.B., Ch.B. St. And.	St. Andrew's Univ.	1,495
Devas, H. C.	L.R.C.P., M.R.C.S.	St. Thomas's Hosp.	1,420
Burns, H.	M.B., Ch.B. Edin.	Edinburgh University	1,405

The above-named gentlemen will undergo a course of instruction in special subjects at Haslar Hospital, on the completion of which another examination will be held, and prizes consisting of a gold medal, a silver medal, and three navy regulation pocket cases awarded. The final position on the list will be determined by the combined results of the London and Haslar examinations.

Public Health

AND

POOR LAW MEDICAL SERVICES.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Brighouse.—The annual report of Dr. Martin (M.O.H.) shows that the birth-rate of Brighouse for the past year averaged 20.21 per 1,000 and the death-rate 14.5, against rates of 25.5 and 14.7 respectively for the whole country. The zymotic death-rate was much higher than the previous year, due largely to an epidemic of measles which led to the partial closing of six elementary schools, and primarily caused fourteen deaths. There was no small-pox, and very little scarlet fever.

Wallasey Urban District.—Mr. T. W. Naylor Barlow, Medical Officer of the Urban District of Wallasey, near Liverpool, has just published his first annual report for the district, to which he was appointed late in the year 1907. The district is becoming a popular suburb of Liverpool on the west side of the Mersey. It comprises 3,408 acres, and has a population estimated at about 71,000 in the middle of last year. The birth-rate was 24.2 per 1,000, and the death-rate was at the low figure of 12.7. The population is growing with great rapidity, having been only 21,000 in 1881. In view of the expressed opinion of the local medical practitioners the Notification of Births Act has not been adopted. A lady sanitary inspector visits houses in which births have been registered as having taken place and gives advice as to the feeding of the child. It has occasionally been found that the baby had died before the visit, perhaps, Mr. Barlow suggests, from a cause which a little timely advice might have prevented. He reserves his opinion as to the desirability of adopting the Act until he has had further experience of the district. The infantile mortality is exceptionally low—namely, 101 per 1,000—although in 1898 it was 168. Only 1 case of small-pox had occurred since 1904, the patient being a man who was landed from a ship. Energetic measures were taken, including vaccination of contacts, and there was no spread of the disease. Scarlatina was notified 248 times, most of the cases being near the end of the year, and is attributed to introductions from Liverpool and Birkenhead, chiefly as the result of Christmas shopping. The question of return cases is discussed at some length in connexion with 9 cases which might be so classed; 6 of these, however, were apparently not of that nature. Mr. Barlow evidently doubts

whether true return cases are common, and shows that some of them are merely due to coincidence. He also points out that they occur most frequently in the cold months and when the wards are full, and that they are associated with enlarged tonsils and adenoids almost invariably, and most frequently in connexion with children who have been kept a longer time in hospital than usual. They occur very rarely or never in connexion with cases discharged before what is known as the normal period of isolation has elapsed. He believes the existence of rhinitis is the chief reason of the persistence of infection, and does not attach importance to the presence of delayed or prolonged desquamation. He is of opinion that children, as a rule, are kept too long in hospital. It has been the common practice to fix six weeks as the period of infection, probably because desquamation usually continues for about six weeks; but no one who has had a large experience of scarlet fever in hospital now believes the desquamation *per se* has anything to do with infection. Six weeks he thinks is generally too long, but each case must be treated on its own merits. Cases with nasal discharge are kept in indefinitely, but Mr. Barlow doubts the wisdom of this practice since the cases are continually being reinfected. Typhoid fever has diminished greatly during recent years. In the 34 cases that were notified no connexion with sewer and drainage defects could be detected. Measles and whooping-cough, as elsewhere, have been the intractable diseases, and so far offer little hope of being dealt with in the way of prevention. Although the district is mostly well settled the sanitary property question is not unknown, and twenty-one houses have been presented for demolition, and other property has been made sanitary. The work done has been very creditable for the first year since the appointment of whole-time M.O.H. Mr. Barlow, however, sounds a note of warning against demolishing poor houses too quickly, owing to the difficulty in rehousing the displaced tenants.

Health of Abercrombie.—The medical officer of health for Abercrombie, Dr. J. A. Jones, in his annual report states that the birth-rate was 39.1 per 1,000 and the death-rate 19.4 per 1,000; infantile mortality-rate was 162 per 1,000 registered births. This figure, he says, is far too high, but in 1899 and 1897 the figures were 253 and 230 respectively. Diarrhoeal diseases alone caused nearly half the deaths among infants, and 24 out of 54 were bottle-fed babies, and he believed that through artificial feeding more children were killed by mistaken kindness, through ignorance, than wilful neglect. Intemperance was also a factor in the increase of infantile mortality, and the prevalence of drinking amongst women was deplorable, and they could not too strongly support State-directed efforts towards lessening the opportunities of getting drunk. The council, he urged, should see that the houses of the people were fit to live in, and that the streets should be free from dust and refuse. The town had been placed to much inconvenience and discomfort by the want of a plentiful and pure supply of water. The report was discussed at a meeting of the Town Council held on May 12th. It was decided to call the attention of the County Council and the Neath Rural Council to the matter of the pollution of the river Afan. The surveyor was instructed to see that the floors of new houses were concreted as far as he possibly could. It was explained that the water supply from the Ystradfellte reservoir could not be secured under two and a half years. This matter was referred to the Waterworks Committee. The clerk was asked to write the Neath Urban District Council, suggesting that the two authorities should go in jointly for a dust destructor. As to the infantile mortality, an alderman asked if it was not a fact that a large number of children were fed on tinned milk, and, although 560 samples of fresh milk were taken during the year, not one sample of tinned milk was taken. Dr. Jones said that matter was under the control of the County Council. It was eventually resolved to take samples of all tinned milk sold in the town for analysis, and to circulate with mothers and nurses, asking them to abolish feeding bottles with tubes.

URBAN DISTRICT COUNCILS AND THEIR MEDICAL OFFICERS.

ESTERINA LENTE writes as follows: "An urban district council wishes to change its medical officer on account of his residing out of the district. The council are seeking medical men residing in the district, and the urban district councillors wish to appoint one or other of them. Must the post be advertised? and is the sanction of the Local Government Board necessary for the change to be effected?"

"* We are not aware of any general order, rule, or regulation which necessitates the post of medical officer to an urban district council being advertised previous to the appointment being made. When any such appointment has been made by the council, it has to be reported to the Local Government Board and confirmed by that Board before being brought into actual operation.

The thirteenth meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act, 1902, was held at the Privy Council Office on May 19th, Mr. Almeric W. FitzRoy, the Clerk of the Council, in the chair. The following witnesses attended: Mr. A. Rivers-Willson, Ph.D., L.S.A., Mr. E. Parker Young, L.S.A., M.R.C.S., Mr. J. Theodore Dodd.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL. The offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Attilioqui, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Attilioqui, London*.

TELEPHONE (National).—

2631, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.
2630, Gerrard, BRITISH MEDICAL ASSOCIATION.
2634, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS forwarded to the OFFICE of THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

"We would request correspondents who desire to ask questions in this column not to make use of such signatures as 'A Member,' 'A Member B.M.A.,' 'Enquirer,' and so on. By attention to this request much confusion would be avoided.

Correspondents are asked to write upon one side of the paper only.

DR. CAMPBELL (Uley, Gloucestershire) desires to hear of a village in North Italy where a patient with delicate lungs would find shelter from prevailing wind, sunshine, moderate elevation, and good lodgings.

THE CONSCIENCE CLAUSE.

DR. CHISHOLM (Halifax, Nova Scotia) asks: "What is the general attitude of the profession towards the Conscience Clause re vaccination? Does it tend to increase the number of unvaccinated, or cause much trouble to health boards?"

"* (1) The profession generally in this country appears to regard the Conscience Clause as a weak concession on the part of the Legislature, but recognizes that the clause was intended to suppress the martyrdom sought by many anti-vaccinators in order to give prominence to their agitation. (2) During the first ten years the number of exemptions averaged only about 5 per cent. of the births per annum. Last year it was made easier to obtain exemption, and the number of certificates granted was about three times larger than in the previous years. (3) The health boards do not administer the Vaccination Acts. Many medical officers of health have reported their anxiety to the local sanitary authorities, and the provision of adequate accommodation in case of outbreaks of small-pox is already receiving renewed attention. The Conscience Clause does not appear to diminish the number of those applying for vaccination when small-pox is prevalent.

LIP READING AND STAMMERING.

DEAF asks to be referred to a book or books explaining the teaching of lip reading to the deaf; also something on the treatment of stammering.

"* Our correspondent might consult the article entitled *The Treatment of Stammering* (and Lalling), by Dr. H. G. Langwill, published in the BRITISH MEDICAL JOURNAL, 1901, vol. ii, p. 130. Of books, the following may be found useful: *Wyllie's Disorders of Speech* (London: Simpkin, Marshall, and Co., 1894, 18s.) gives the physiological aspects of the subject, and practical remarks on the treatment of stammering. *A Series of Lessons on Articulation and Lip Reading*, by Richard Elliott, Principal of the Margate Institution for the Deaf (published by the Committee of the Institution, 93, Cannon Street, London, E.C., 2s. 6d.) is a good practical treatise. *Practical Lip Reading*, by E. F. Boulton (London: Upcott, Gill; New York: Charles Scribner's Sons), would be suitable in cases of adults.

INCOME TAX.

CYMO's income is made up as follows: From practice, after paying expenses, £195; rent of land, £5 10s.; total, £200 10s. He pays £49 for life assurance premiums, and has two children under 16 years of age. He asks whether he is liable to pay income tax.

* * Provided that the Budget proposals become law, our correspondent will not be liable. He will be entitled to the following allowances: Abatement, £160; life assurance premiums (one-sixth of total income), £33 10s.; allowance for children (£10 for each), £20; total allowances, £213 10s., which more than covers the amount of his income.

VACCINATOR received in February, 1909, the Government grant for efficient vaccination, it being three years since he received the previous grant. He asks whether the full amount received should be returned for assessment to income tax for the year 1909-10, or whether it should be averaged and the amount spread over the next three years.

* * The appointment of public vaccinator is a public office within the meaning of the Income Tax Act, 1942, and the remuneration received in respect of any such office is taxable under Schedule E on the amount receivable during the current year. This rule, however, is subject to an exception. The profits of any such office which fall under the head of "perquisites," as distinguished from ordinary remuneration, are taxable, either on the amount received in the preceding year or on the average amount received during the three preceding years. The answer therefore turns on the question whether the grant is to be regarded as ordinary remuneration or as a "perquisite" of the office of vaccinator. We incline to the view that it is a "perquisite," and that our correspondent is entitled to average the amount for the purposes of his income-tax return under Schedule E.

ANSWERS.

G. A. D.—The apparatus in question does not appear to differ in any way from the numberless electrical appliances of a similar kind which are advertised, and although in common with most of them it may have a good effect in chance cases, a leading authority in electrical treatment to whom we submitted the inquiry does not recommend it for insomnia.

THE CANARY ISLES.

W.—The Canary Isles are Spanish possessions, and, so far as we are aware, foreign practitioners are subject to the same regulations as in Spain. Nominally these necessitate the passage of exactly the same examinations as those undergone by Spanish students, but the extent to which the regulations are enforced seems to vary considerably from time to time.

LETTERS, NOTES, ETC.

A CASE OF CALENTURE.

MR. E. KNIGHT (Gravesend) writes: In an article on calenture which appeared in the BRITISH MEDICAL JOURNAL of February 27th, under the heading of Nova et Vetera, I stated that, according to old writers, those who suffer from this malady at sea become delirious, and, imagining it to be green fields, desire to leap into it. Also I remarked that I had been unable to find out from seafarers that they have any knowledge of a fever at sea producing this peculiar form of delirium. Since then a reader of the JOURNAL, who was formerly a ship's surgeon, has kindly sent me particulars of a case of "calenture" which came under his own observation. About twelve years ago a young man was found climbing over the rail of a vessel sailing in the tropics, preparatory to jumping into the sea. In explanation of his conduct he said that he saw his sister in a green field gathering flowers, and was climbing over the gate to go to her. He was of temperate habits, and it was not long before he recovered his mental equilibrium.

A QUESTION OF LIFE OR DEATH.

DR. BALDWIN (Bathurst, Gambia, West Africa) writes: The following incident may be entertaining to some readers as a sample of the intelligence of the native male nurses employed in some of our West African hospital wards: Recently a man was admitted with a badly-fractured skull and lacerated brain. I instructed the nurse on night duty to let me know every morning at 6.30 if the man was alive or dead, as in these hot places we make post-mortem examinations as quickly after death as possible. The nurse followed my instructions carefully. The patient died in the evening and I made the post-mortem examination about 11 o'clock at night. As I was leaving the mortuary the nurse came up to me and said: "Please, sir, shall I call you at 6.30 to-morrow morning to say if the man is alive or dead?"

AN A POSTERIORI ARGUMENT FOR PSYCHOTHERAPY.

WE find the following instructive story in an unexpected place, that organ of "occult and mystical research," *Light*. Our contemporary cites the story because it is recorded in "a

very serious—in fact, an eminently religious—American journal." It is said that Dr. Weir Mitchell gave a hysterical young lady a book on psychotherapy, with the advice to study it and cure herself. About a fortnight later the famous neurologist received a note from his patient in which she said: "That book is a prize. The other day I had an attack of the old sort—laughing and crying together—and the trouble was brought to an end in two minutes simply by the use of the book. Mamma spanked me with it." This case opens up a new use for psychotherapeutic and Christian Science literature. The books might be bound with a view to the special mode of application indicated.

A NOVELTY IN GYNAECOLOGICAL NOMENCLATURE.

In the May number of the *London Hospital Gazette* it is stated that a short time ago a patient attended an out-patient department with a card bearing the legend "Virginity." It may be believed that an inflamed virginity is a troublesome affection, but until Mrs. Eddy has fully revealed her method of propagation of the human race in a spiritual fashion, there is always a hope that it may find a natural cure.

"IN THE NAME OF THE PROPHET—SOAP"

MESSRS. JOHN KNIGHT, Limited, write: Our attention has been called to the leader in your issue of May 7th, under the above heading, and as we should much regret if by publishing the letter referred to we have unwittingly trespassed, we consider it only right that we should inform your readers that although the letter was quite unsolicited by us and we considered it contained Dr. Forbes-Ross's permission to make whatever use we cared to of it, we withdrew its publication on hearing from Dr. Forbes-Ross that he did not intend it for publication, and this we did all the more readily on becoming aware of the views expressed by the President of the Royal College of Surgeons contained in a letter Dr. Forbes-Ross sent us for perusal. We need hardly add that we much regret any inconvenience that may have been caused through a misapprehension on our part.

* * In addition to the cleansing virtues which it may be presumed to possess, the soap manufactured by Messrs. John Knight, Limited, would seem to have the peculiar property of producing, both in those who make it and in some at least of those who use it, a state of innocence which in these days of villainy, as Falstaff says, is as rare as it is enviable.

QUININE IN SYPHILIS.

T. A. P. writes: I wonder whether it has occurred to any other medical practitioner as it has to me that since quinine is a deadly poison to the malarial parasite there is a presumption that it would be also to another protozoal parasite, the *Spirochaeta pallida*. I have seen no reference to such a treatment of syphilis, and am not aware whether any trial of it has been made. I have seen much opportunity of dealing with it, a fair trial. Since it occurred to me I have had only one opportunity of administering it in syphilis, and that to a case already showing secondary symptoms. I did not dare to withhold mercury, but gave concurrently 2 grains of quinine three times daily. The case, which promised to be severe, ran an exceptionally favourable course, and I was particularly struck with the absence of cachexia and a positive improvement of the patient's complexion. I should like to see a recent case kept in a condition of cinchonism as long as it could be borne and the subsequent history watched. I venture to make this crude suggestion in the hope that some one more favourably situated than I am may be led to give it a fair trial.

THE EQUALIZATION OF COEFFICIENTS.

THE following sample of solution of a problem in pathological algebra has been sent to us by a lady at Oxford:

I happened to overhear the following, and thought you might like to use it in your paper:

Younger Sister: Yes, I do like him; I almost think I would like to marry him.

Elder Sister: "My dear, No! Why, his mother died of consumption."

Younger Sister: "Well, so DID MINE."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0 4 0
Each additional line	0 0 6
A whole column	2 13 4
A page	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at Postes Restantes addressed either in initials or numbers.

An Address ON VOLVULUS.*

BY
HERBERT F. WATERHOUSE, M.D., C.M.EDIN.,
F.R.C.S.ENG.,

SURGEON AND LECTURER ON SURGERY, CHARING CROSS HOSPITAL;
SENIOR SURGEON, VICTORIA HOSPITAL FOR CHILDREN;
EXAMINER IN SURGERY, UNIVERSITY OF LONDON.

I HAVE chosen Volvulus as the subject of my remarks, for the reasons that this morbid condition is, I am convinced, by no means so rare as is generally supposed; that it is not often diagnosed prior to opening of the abdomen; that it is, in my opinion, the most fatal of all the many varieties of intestinal obstruction, although if treated in good time its mortality should be far less than it now is, as operation in the early stages of the affection is at least as likely to prove satisfactory as laparotomy for any other variety of intestinal obstruction; and, lastly, that it will afford me the opportunity of making some observations on the subject of mechanical intestinal obstruction.

We must at the outset distinguish between two great classes of intestinal obstruction: (1) those in which there is mechanical obstruction only, and (2) those in which to mechanical obstruction there is added strangulation of the intestine. In the latter case the vitality of the bowel wall is seriously impaired, with the result that necrosis, with permeation of the strangulated segment of bowel by infective microbes, takes place, with or without perforation of the intestine, and thus septic peritonitis arises. This is practically constant in volvulus unrelieved by treatment, in which condition the later symptoms owe their existence chiefly to infective peritonitis rather than to mechanical obstruction. A few hours' delay in relieving the obstruction may do little harm in a case of pure mechanical obstruction, while they may make all the difference between life and death in one such as volvulus, in which the lesion is obstruction *plus* strangulation.

The subject of volvulus has impressed itself upon my mind owing to the fact that within the past six months I have seen, I believe, no less than five cases of this lesion, one of which was a combined volvulus of both small and large intestines, so that I have encountered during this short period six examples of intestine rotated round its mesenteric axis. One case I admit recovered without operative treatment, and you may therefore feel some doubt about my diagnosis, but even if we exclude this case it is remarkable that so many examples of volvulus should have occurred in so short a time in the practice of a single surgeon.

Two distinct varieties of volvulus must be mentioned. In the more common variety the intestine (commonly the large bowel) is rotated around its mesocolic or mesenteric axis in such a manner that the lumen of the intestine is obstructed. In the rarer variety, of which the above five cases offer one example only, the small and the large intestine are both rotated around their mesenteric and mesocolic axes, so that a double or compound volvulus results with symptoms more urgent than in the more frequent variety.

Volvulus most frequently involves the sigmoid colon, and it will be noticed that this segment of the intestine was affected in four out of the five cases mentioned. More rarely the caecum and commencement of the ascending colon constitute the intestinal segment concerned; this was the case in one only of these cases. Still more rarely is a volvulus of the small intestine observed; this was noticed once only, and then in combination with volvulus of the sigmoid flexure.

Volvulus of the Sigmoid Flexure.

This, by far the most frequent form of volvulus, is found either uncomplicated—that is, the sigmoid colon is twisted upon its mesocolic axis (three instances)—or in combination with a volvulus of the small intestine (one case).

About 75 per cent. of all cases of volvulus are instances of the sigmoid colon rotated around its mesocolic axis.

The so-called sigmoid flexure has, as Sir F. Treves has remarked, a greater resemblance to the capital letter Ω .

The rectum of our student days has, by modern anatomists, been shorn of its first part, which is now included with the sigmoid colon under the name of the omega loop.

This omega loop varies more in length than any other structure in human anatomy. On the operating table I have known it as short as 7 in. and as long as 26 in. It will be observed that in cases in which the sigmoid colon approximates to the length of its mesocolic attachment to the posterior abdominal wall no volvulus can occur, whilst in instances in which the sigmoid colon is several times the length of its parietal attachment there is a definite predisposition to the occurrence of a twist of the colon around its mesocolic axis. In a long omega loop the comparatively narrow pedicle of attachment serves as a predisposing cause of volvulus. The nearer the two extremities of the omega loop approach one another, and the longer the segment of bowel, the more likely is rotation around the narrow mesocolon to occur. Elongation of the sigmoid colon might naturally be considered to be of congenital origin, but against this view I may state that during many years' service on the staff of a large children's hospital I have never met with a case of volvulus of the sigmoid flexure in a child.

I am convinced that the common cause of elongation of this segment of the large intestine is constipation. The omega loop laden with hardened faeces drops down into the cavity of the pelvis, and the weight of the faecal mass tends to lengthen the distance between the parietal attachment of the mesocolon and the bowel, and at the same time to approximate the two ends of the omega loop. The mere weight of the faecal content of the omega loop has much to do with starting the rotation of the intestine around its mesocolic axis.

Two varieties of rotation are possible. In that which is of by far more frequent occurrence the upper part of the omega loop travels downwards and forwards anterior to the lower part of the loop, so that the end of the descending colon touches and lies anterior to the upper rectum (type *rectum en arrière*, Potain). In the far less frequent variety the upper part of the omega loop passes downwards and backwards, so that the end of the descending colon is in contact with and behind the commencement of the rectum (type *rectum en avant*).

The extent of rotation of the colon around its mesocolic axis is very variable and may be from about half a circle—that is, an angle of 180 degrees—to three complete rotations. Anything short of 180 degrees will not produce symptoms of total obstruction or of strangulation of the intestine. It is commonly taught that once a volvulus has occurred it cannot replace itself spontaneously. This, I am convinced, is an error, and I shall adduce evidence in support of my contention. In cases in which reposition does not soon take place the volvulus rapidly becomes greatly distended with gas, as it is a closed sac with putrescent contents; at the same time its walls suffer intense vascular engorgement. The longer the volvulus is allowed to remain unreduced the more difficult is it to replace the bowel. Even if this be accomplished, the volvulus recurs immediately. No force must be used to untwist a volvulus, otherwise the damaged bowel will assuredly burst. An incision must be made into the tense intestinal loop to give exit to the distending gas and contained faecal matter; reduction of the volvulus is then easily accomplished and the twist does not recur.

A volvulus of the sigmoid colon may attain enormous dimensions. I have seen one which reached nearly to the liver, and overlay and thus hid from view the whole of the rest of the intestine.

The intestinal wall is always seriously damaged. In colour it may be dark violet-red to black; it is always swollen and very friable. Linear ruptures of the peritoneal and muscular coats are commonly seen, but the resistant submucous layer saves the mucosa from participating in the tear. In the worst cases numerous spots of gangrene of the size of a sixpenny piece, and affecting the whole thickness of the bowel wall, may be observed; in rare instances they lead to perforation of the bowel. Peritonitis always occurs if the case last sufficiently long, owing to the fact that the damaged intestinal wall is

*Delivered to the Norwood Division of the British Medical Association.

permeable to micro-organisms from inside the twisted loop of bowel, and it rapidly becomes generalized.

Volvulus of the Sigmoid Colon Combined with Volvulus of the Small Intestine.

One example of this rare condition was met with in my five recent cases. A segment of ileum with a long mesentery had apparently passed across the sigmoid colon at its lower part. It lay external to the line of the omega loop. The latter had twisted around the pedicle of the small intestine coil, and presented the normal aspect of a volvulus of the omega loop. I was fortunately able to untwist the volvulus, and the patient is now well. This is the most extraordinary case of volvulus that I have yet seen.

The patient, a woman, was admitted into Charing Cross Hospital on December 26th, 1908, with severe symptoms, enormous abdominal distension and constant vomiting. Enemata given every hour soon caused abatement of the symptoms and she desired to be discharged, thinking herself cured. Flatus and even fluid faeces were passed, but a lump could still be felt. Thirteen days later, on opening the abdomen, the above-described condition was found. The rotation in the case of the sigmoid volvulus was through an angle of 180 degrees, and the volvulus was held in this position by an adhesion to the left Fallopian tube. The loop of ileum was rotated through an angle of 130 degrees only.

This case lends support to the views of von Samson, who holds that a half-turn volvulus—that is, the rotation through an angle of 180 degrees—does not occlude the lumen of the bowel or produce symptoms of strangulation of the intestine.

Volvulus of the caecum and lower part of the ascending colon was found in one of my five recent cases.

It occurred in the case of a man admitted into my ward at Charing Cross Hospital, January 7th, 1909, suffering from carcinomatous stricture of the sigmoid colon. In this patient the distended caecum was rotated along with the lowest 3 in. of the ascending colon on its mesocolic axis through an angle of 360 degrees (a complete circle). The volvulus was a huge one and strangulation had lasted for more than four days. The wall of the caecum exhibited numerous round patches of gangrene, and for this reason, after the damaged segment of intestine had been incised, it was found necessary to leave it outside the abdominal cavity.

Volvulus of the Small Intestine.

In this variety the rotation may be from left to right or from right to left, and the loop of bowel, commonly the lower ileum, is twisted on its mesentery through a complete circle.

Incidence of Volvulus.

Volvulus is stated by various authors to be responsible for from 3 to 4 per cent. of all cases of intestinal obstruction. In my practice its frequency has been at least double that given above. In about three-fourths of all cases the sigmoid colon was the segment of intestine involved.

The condition is far more common in the male than in the female, fully 80 per cent. occurring in the former sex. The most frequent age is 50 to 60 years.

Volvulus is only possible where the mesentery or mesocolon is long. Hence its frequency in the sigmoid flexure, in the ileum, and in the caecum when this part possesses a mesocolon.

Spontaneous Reduction.

Spontaneous reduction of a volvulus is an event that is, I am convinced, by no means infrequent. I have once seen it occur. I performed ovariectomy in a thin woman, and, as the result apparently of the sudden removal of the support afforded by the tumour, the omega loop rotated on its mesocolic axis through an angle of 180 degrees. I was about to untwist it when, to my surprise, the twist undid itself spontaneously. I think that in many cases volvulus of the omega loop of mild degree takes place, occasioning sudden abdominal pain in the left iliac fossa, and is reduced either spontaneously or as the result of rectal enemata. It will be observed that in one of my cases I believe the recent volvulus to have been reduced by enemata. BROTHIE'S CASE.

This case occurred to a friend of mine, seen in consultation with Drs. Carruthers and Douglas of Upper Norwood. To the kindness of my friend, Dr. S. W. Carruthers, I am indebted for the account of the history of the case. "About 11.30 a.m. the patient was seized with intense abdominal pain, which rapidly abated sufficiently to allow him to continue what he was doing. An hour later the pain again became agonizing, and the patient

was writhing on the floor when I (Dr. Carruthers) saw him. Countenance anxious and pale, pulse 85. Patient located the pain definitely at a point in the left iliac region. The abdomen was not distended nor rigid. No flatus had been passed since the original paroxysm of pain. Patient was at once put to bed. No opium was given, for fear of masking symptoms. Two soap-and-water enemata were given in rapid succession. The first (30 oz.) brought away a small solid motion from the lower part of the rectum; the second (40 oz.) brought away nothing further, but gave the patient immediate sense of relief. It was followed, however, by sharp vomiting. Thereafter no severe paroxysm of pain, no flatus passed, and the pain had now become dull, not much more than acute discomfort, with occasional gripping. Enemata were continued, and the patient vomited twice. At 6.30 p.m. Mr. Waterhouse and Dr. Douglas saw the patient with me in consultation. Our unanimous opinion was that it was a case of volvulus of the sigmoid flexure, which it was hoped had been reduced by the enemata already administered. Some tenderness on pressure was elicited over the sigmoid flexure. It was decided to continue the use of enemata and to await events for a few hours. At 10 p.m., after discussion with Mr. Waterhouse over the telephone, it was decided to run the risk of postponing abdominal exploration, owing to the cessation of vomiting and general *bien être* of patient. Enemata given at intervals during the night, nothing but water by mouth. Between 7 and 8 a.m. flatus was passed several times. Fluid food was now allowed, and calomel was given, 3 grains hourly, after a second consultation with Mr. Waterhouse at 5 p.m. Bowels acted next morning, a fairly copious stool, and recovery was thereafter uneventful."

Can there be any doubt that this was an instance of volvulus of the sigmoid flexure untwisted by the second enema administered by Dr. Carruthers, which, though it brought away nothing, gave instant relief to the patient? I have no doubt on the subject, though I admit that I cannot prove my contention. I have come across several such cases, and I believe them to be far from uncommon.

Symptoms.

Volvulus is always of sudden onset and commonly commences in a patient in sound health. Abdominal pain about the seat of the twist is constant, it is commonly severe and continuous, but may be colicky; the constant pain is due to the twist, the exacerbations to the violent increased peristaltic movements above the volvulus. The other symptoms depend largely upon the locality of the volvulus. If it affects the small intestine the symptoms are those of acute intestinal obstruction. If, on the other hand, it occurs in the lower part of the large intestine the immediate symptoms of obstruction may be, at first, comparatively trifling. Vomiting is urgent and constant in the former case, whilst it may never occur in volvulus of the omega loop. My last case of volvulus of the caecum did not vomit either prior to or after the operation.

In volvulus, as in other abdominal diseases, tenderness is a far more valuable localizing symptom than pain. The latter may be referred, the former corresponds to the situation of the lesion. Distended coils of intestine may exhibit violent peristaltic movement which may be seen to cease abruptly at a definite spot. Local meteorism may enable a diagnosis to be made, and such localizing symptoms are often of real value. Soon the twisted intestine and mesentery undergo venous engorgement and cedema, and both exude plastic lymph which may glue the volvulus to adjacent coils of intestine, and thus present a formidable obstacle to reduction of the lesion. Not until the vitality of the bowel wall has been so impaired as to permit of its permeation by microbes from inside the strangulated bowel will septic peritonitis commence, but when once started this infective process spreads rapidly and soon becomes diffuse. Extreme intestinal distension is chiefly noted in cases of volvulus and of generalized septic peritonitis. As a point of differential diagnosis, it may be mentioned that tenderness on pressure is far more marked in the latter condition.

The onset of gangrene of the twisted bowel is indicated by the pulse becoming rapidly weak and quick and by the septic appearance of the patient.

A hyper-resonant note may frequently be elicited over the distended volvulus. The diagnosis of volvulus I have found far easier in the early stages of the malady than when the characteristic symptoms are concealed in great measure by the general tympanitic distension of the abdomen and the onset of peritonitis. In the diagnosis of volvulus it must be remembered that the onset is very sudden, that the obstruction of the intestine is complete, that the volvulus can often be felt as a tense tumour (resembling an india-rubber ball intensely inflated) which

is always tender on pressure, hyper-resonant on percussion, and commonly the seat of pain.

A volvulus that is very recent and in which no secondary changes have occurred in the twisted mesentery may, I am convinced, be reduced occasionally spontaneously, and more frequently by the aid of copious rectal enemata, especially if the rotation has only been through half a circle or thereabouts. When, however, the volvulus has been in existence for some time, and the rotation corresponds to a complete circle, or more, and when secondary changes have occurred in the mesentery and intestinal loop, then death from obstruction and septic peritonitis, otherwise inevitable, can only be avoided by opening the abdomen and undoing the twist. The more complete the twist and the higher up in the bowel the volvulus the more urgent is the danger.

Treatment of Volvulus.

The loop of bowel twisted upon its mesenteric axis provokes vigorous peristaltic movements in the intestine above it. The first indication in treatment is to calm this dangerous peristalsis, which tends markedly to aggravate the existing obstruction and strangulation. No food must be given by the mouth, but I never forbid water, as the suffering of the patient is greatly augmented by the intense thirst due to frequent vomiting, so often a prominent symptom in intestinal obstruction of all kinds. Should the ejecta consist largely of bile or the contents of the small intestine it adds greatly to the patient's comfort to wash out the stomach either by the stomach tube or, as I prefer, by giving water freely by the mouth. Many authorities advise that the exaggerated movement of the bowel above the site of obstruction should be calmed by opium administered by the stomach or by a hypodermic injection of morphine. I earnestly beg of you never to allow yourselves to be persuaded in any case of intestinal obstruction to use this, in such cases, treacherous and deceptive drug. I yield to none in my admiration for morphine as a mitigator of pain, but in intestinal obstruction I regard it as a deadly drug. How often have I at the bedside, racking my brains to make a diagnosis in a case of acute abdominal trouble, regretted that I could not discount the effect of even a single dose of morphine! Over and over again have I felt that I might have made a more correct diagnosis and by timely operation have been enabled to save life had it not been that my judgement was obscured by the statement both of the medical attendant and of the patient that the condition of the latter was evidently improving, as he was certainly better than he was six or eight hours previously. I have in many such cases neglected to make full allowance for the effect of even a single dose of morphine, and have fallen in with the request to wait to see how the patient was the next day, to learn at the operation that I had waited too long. Pray do not think that I am unreasonable in this matter. I fully understand that the practitioner's duty in the eyes of his patient is to give relief to his most urgent symptom—that of intolerable pain—and that a hypodermic injection of morphine will accomplish this. I beg of you, however, to remember that an operation followed by death will bring discredit on the surgeon, and that in common fairness to him he should be allowed to see the patient as he really is rather than with his sensibility to pain and tenderness annulled by a dose of morphine. If I, as a surgeon, were asked how I would define a first-rate practitioner, I would be inclined to answer: One who does not administer morphine in acute abdominal disease until a fairly confident diagnosis has been arrived at.

I am a profound believer in the value of rectal enemata in volvulus. I am convinced that I have seen many cases both of volvulus and of intussusception which have been reduced by the use of repeated rectal enemata. I admit that clear proof of this is wanting, but I have no doubt in the matter. I would draw special attention to the value of the genu-pectoral position during the administration of enemata. I am certain that I have been enabled more than once to reduce a volvulus of the sigmoid colon by repeated enemata administered in this position in cases in which enemata administered in the dorsal position had failed to accomplish reposition. My belief is that cases of volvulus of the sigmoid colon which can be reduced by rectal enemata are those only which are of recent origin

(less than twelve hours), and in which the angle of rotation is less than 270 degrees. You will remember that we have seen that there are two varieties of volvulus of the omega loop. In the more frequent, in which the upper part of the loop travels downwards, forwards, and inwards anterior to the lower part of the loop, it is clear that distension of the lower segment of the bowel will have a tendency to undo the twist. In the less frequent variety, in which the upper part of the loop passes downwards, backwards, and outwards posterior to the lower end of the loop, distension of the lower bowel will tend rather to aggravate the twist.

I have clinical evidence for this. In two cases of volvulus of the sigmoid flexure I found after opening the abdomen that the volvulus in the first-mentioned variety was readily reduced by rectal injection, which failed in the example of the latter variety, and in fact seemed to render the twist tighter than before.

What is the mortality of volvulus? I cannot tell, but I know well that it is appallingly high. It is certainly the most fatal form of intestinal obstruction, and yet it ought to be one of the least fatal. I am convinced that the cause of the awful mortality is that the operation is, in almost every case, postponed until the strangulated intestine is beyond recovery.

Few operations have yielded me happier results than those for early volvulus of the sigmoid colon; none more terrible consequences than those in which I have been called to a similar volvulus on the fourth, fifth, or sixth day subsequent to the onset of the condition, to find the strangulated bowel gangrenous and diffuse peritonitis already developed. One great reason for the delay that has occurred is the fact that in about half of my cases of volvulus of the sigmoid there has been no vomiting, and the case has therefore appeared to the medical attendant not to be one of urgent intestinal obstruction.

The two conditions that make for success in the treatment of volvulus are immediate diagnosis on the part of the practitioner and immediate reduction of the volvulus by the surgeon. Should either of the two fail in his part, the probable result will be the death of the patient.

In very recent volvulus, especially of the omega loop, reduction may be accomplished by rectal enemata in a certain proportion of cases. Should they fail, and this will frequently happen, the surgeon must in every instance open the abdomen. The incision should, I think, in every case, be made in the linea alba, for the reason that by a median incision every viscus in the abdomen may be examined.

There are few things more distressing than, after making an incision in the left inguinal region for the relief of a sigmoid volvulus, to discover that the caecum has burst owing to over-distension, and that a second incision is called for to deal with this terrible lesion. I speak from painful experience. The abdomen having been opened in the mid-line the caecum is in all cases of intestinal obstruction to be examined immediately. Its condition at once gives information of great value. In volvulus the caecum itself may be the seat of the lesion. If the caecum be empty the obstruction is obviously in the small intestine; if it be distended, in the large bowel. In all cases of two or three days' standing there will be found marked distension of the intestine above the site of the obstruction. The volvulus owing to its huge size will be readily found, and must if possible be brought outside the abdominal incision. This, owing to the undue length of the mesentery (or mesocolon), I have always been able to accomplish. The next step is to replace the twisted bowel into its usual position. In the majority of cases this reposition is by no means a simple matter. Should the volvulus be of only a few hours' duration the adhesions will be slight or absent. Untwist the strangulated loop in a direction the reverse of that in which the twist occurred and deal gently with it. In the majority of instances the bowel loop will immediately spring back into its former vicious position. In almost every case I have found it necessary to open the distended loop of bowel on its antimesenteric aspect in order to evacuate the gas and faecal contents. Not only must the contents of the volvulus be allowed to escape through this incision in the bowel, but the distended intestine above the volvulus must be evacuated of its putrefactive accumulation in order to prevent the risk of auto-infection. This evacuation of the bowel above the constriction is notably aided by irrigation,

of the distended coils of intestine through the opening. Once the volvulus has been emptied of its contents reduction of the twist is almost invariably possible, and in no instance have I then known the twist to recur. Many surgeons now advise closing the incision in the bowel and the return of the latter into the abdominal cavity. I admit freely that this is the ideal course to pursue, but I confess that I have never dared to follow it. I have always ligated the margin of the incision in the bowel to a glass tube and drained the distended and damaged bowel for several days. In most cases in which the patient has recovered, the fistulous opening in the bowel has closed spontaneously at the end of some weeks.

In the worst cases it is obvious that gangrene of the strangulated loop of bowel has occurred, and the condition of the patient is always extremely perilous. The ideal treatment would appear to be resection of the gangrenous intestine and union of the proximal and distal segments of the bowel either by end-to-end or by the far safer lateral anastomosis. This treatment I have never ventured to carry out. In every case of gangrenous volvulus that has come under my care the condition of the patient has appeared to me too desperate to warrant a prolonged operation. I have always, in such cases, been content with bringing the gangrenous bowel and a piece of healthy intestine on each side of it outside the abdominal cavity. In such cases as have recovered I have performed resection subsequently. Making two bites at a cherry may be in general a bad practice, but in surgical procedures of grave moment in which the life of the patient literally hangs in the balance, the operation *à deux temps* is, in many instances, the safer for the patient, and the one that the surgeon is therefore bound to follow.

Once the volvulus has been reduced, can any steps be taken to prevent the recurrence of the condition? In one of my recent cases, under the care of Dr. J. H. E. Brock, the patient, a man aged 31, had had his life placed in jeopardy no less than four times in thirteen months owing to recurrent volvulus of the sigmoid colon. I have endeavoured to convince you that the all-important factor in the establishment of a volvulus is undue elongation of the mesocolon or mesentery. Clearly it follows from this that the object of treatment directed to the prevention of recurrence of the volvulus is to shorten the elongated mesocolon or mesentery. Such an object I have endeavoured to obtain, I think with success, by introducing silk sutures at right angles to the bowel from the intestinal attachment of the mesentery or mesocolon to its root and then tying these. I have thus puckered the mesentery or mesocolon parallel to the axis of the intestine, with the result that the mesocolon or mesentery has been shortened and recurrence of the twist prevented. This measure is, I am convinced, far superior to that commonly adopted of suturing the coil of intestine to the abdominal parietes. It must be the experience of all surgeons that peritoneo-peritoneal adhesions almost invariably either stretch out to form long thin cords, which must constitute a constant danger of strangulation to any coil of intestine that may happen to be ensnared by them, or give way entirely, thus in the case of volvulus permitting the recurrence of the twist of the bowel.

In conclusion, may I remark that I have largely confined my remark to volvulus, but I hope that my observations may be taken as applicable to other forms of intestinal obstruction? It may be objected that I have taken a lesion of very rare occurrence as my topic; but I would urge that volvulus, certainly in its slighter degrees, is by no means so rare as is generally supposed. As to its rarity, my house-surgeon, Mr. E. H. Hogg, M.B., B.S. Lond., can bear me out in my statement that between January 5th and 12th he saw with me no fewer than 4 cases in which the intestine was twisted upon its mesocolic (three times) or mesenteric axis. I know no more delusive abdominal lesion, none more difficult of diagnosis, and none more fatal, owing chiefly to imperfect and tardy diagnosis, than volvulus. Some of you may say you have never come across a case of volvulus in practice, or you have seen but one or two. Within a few days you may encounter your first, second, or third case of volvulus. If so, pray bear in mind my warning. You will probably in such case misconstrue the symptoms. You will think of other conditions. Should vomiting be absent, as is not

uncommon in volvulus of the sigmoid, you will probably deem the case one of no urgency, and you may wait until the hour of successful intervention has passed. If what I have said prove the means of helping you to a correct diagnosis and induce you to have resort to timely operative treatment, with the result that your patient's life is saved, my object will have been attained.

An Address

ON THE

IMMEDIATE AND ULTIMATE RESULTS OF THE OPERATION OF GASTRO-ENTEROSTOMY FOR GASTRIC AND DUODENAL ULCER.*

By LEONARD A. BIDWELL, F.R.C.S.

SURGEON TO THE WEST LONDON HOSPITAL.

THE immediate results after gastro-enterostomy are wonderfully good when we consider the severity of the operation; still I think that those writers who give the mortality at only 1 per cent. rather underestimate the risk, and such a satisfactory result has only been obtained by good fortune and careful grouping of cases, as well as by good surgery. In a series of 132 operations which I have performed for ulcer of the stomach and duodenum (excluding cases of perforation) there have been 6 deaths, or a mortality of a little under 5 per cent. The causes of death in the fatal cases were as follows: Shock after Roux's operation in an exhausted patient, 1 case; shock after operation for repeated profuse hæmorrhages, 1 case; exhaustion after secondary operation for vicious circle, 1 case; syncope after hæmorrhage from ulcer ten days after operation, 1 case; rupture of the ulcer three days after operation, 1 case; and pulmonary embolism on the third day after operation, 1 case.

I consider that the last three fatalities were entirely outside the control of a surgeon, and that the case of death after operation for repeated hæmorrhage must be considered as occurring in spite of rather than in consequence of the operation. In the remaining two cases death was certainly hastened by the operation, although recovery was impossible had no operation been performed. My experience makes me hesitate to assert that the risk of a gastro-enterostomy is practically nil.

While considering the immediate mortality of the operation we ought to bear in mind the mortality of gastric ulcer under medical treatment. There seems to be a great difficulty in estimating this, and it is stated to be from 20 to 50 per cent. by various surgical writers. I cannot but think that even the lower estimate is probably too high, and that a mortality of 10 per cent. would be more reasonable to assume when comparing the results of surgical with those of medical treatment.

So much for the immediate mortality after an operation for gastric or duodenal ulcer. In the non-fatal cases the improvement, with very few exceptions, is wonderful; the patients feel better than they have done for years, and are able to eat and digest any kind of food. This improvement is maintained so long as the patient remains in the nursing home or in hospital, and, were we only considering the condition of patients within a month or two after an operation, we could positively affirm that over 90 per cent. of the cases were completely cured.

The point I wish to discuss is, What is the condition of these apparently cured cases some years after the operation?

Before doing this, I should like to call your attention to the physiological conditions attending a gastro-enterostomy in the case of a simple ulcer. When the opening is first made, the mucous membrane at the edges of the opening becomes congested, partially blocking the opening, and consequently we may have vomiting for the first twenty-four or thirty-six hours; after this the swelling of the mucous membrane subsides and a patent opening is left. Under these conditions, dilatation of the stomach, whether caused by cicatricial contraction or by spasm of the

* Delivered before the Kensington Division of the British Medical Association, January 21st, 1909.

pylorus, is cured, and in the absence of dilatation, with the consequent stretching of its base, the ulcer readily heals. When the ulcer is healed, the spasm of the pylorus ceases and the pylorus again becomes pervious; when this is the case, it is quite certain that the food will pass through the pylorus and not through the gastro-enterostomy opening; this has been proved both by experiments on animals and by clinical experience. One reason for the food choosing the pylorus rather than the gastro-enterostomy opening is that when the stomach contracts on its contents, the muscle fibres tend to form a sphincter round the gastro-enterostomy opening; the other reason is the tendency for all secretions to pass by the natural way if this is not obstructed by a stricture. We shall therefore find, after an ulcer has healed, that the gastro-enterostomy opening, having fallen into disuse, will tend to contract, and may even become completely occluded; in fact, at best it will only act as a safety valve in the case of a fresh spasm of the pylorus.

In cases in which the gastro-enterostomy opening closes, the operation will not have been of very much more avail than successful medical treatment; indeed, it will have acted in very much the same way as a suprapubic cystostomy does in a case of cystitis. These physiological considerations will explain a certain number of cases where recurrence of the symptoms takes place after gastro-enterostomy, and we may conclude that cases of gastric ulcer, in which there is no cicatricial contraction about the pylorus, are not likely to derive permanent benefit from gastro-enterostomy alone. When the ulcer is in the neighbourhood of the pylorus a certain amount of cicatricial contraction of that orifice is bound to occur, and so the gastro-enterostomy opening is not likely to fall into disuse, and consequently the cure of the ulcer will be permanent.

In cases of duodenal ulcer it is quite certain that the cure effected by a gastro-enterostomy is only likely to be a permanent one when severe cicatricial contraction of the duodenum has previously taken place, and in cases without cicatricial contraction there is a very grave risk of recurrence of the ulcer when the gastro-enterostomy opening has ceased to be functional.

In the same way gastro-enterostomy is not a permanent cure for gastritis without ulcer, as the symptoms of gastritis, together with the spasm of the pylorus are quickly cured by the physiological rest given to the stomach, and when these symptoms are cured the gastro-enterostomy opening ceases to act.

In neurotic dyspepsia the operation is not only useless but it is often very harmful, and likely to be followed by results most distressing to both patient and surgeon. The two most pronounced failures I have had were operations on young women, whose first operations had been performed before I saw them, and in whose cases I doubt that an ulcer ever existed.

Taking the operation of gastro-enterostomy alone, I have performed 104 operations on 101 patients (63 females and 38 males); 6 patients died from causes already described, 3 patients had a complete return of their symptoms, necessitating a second gastro-enterostomy; of these, 2 were cases of duodenal ulcer, and the recurrence of the ulcer is explained by my omitting to occlude the pylorus at the time of the gastro-enterostomy. Five patients who were cured by the operation have since died, 2 of bronchopneumonia, 1 from recurrence of a duodenal ulcer after two years and a secondary operation, 1 from cause unknown, and 1 after an interval of two years from cancer of the stomach. In the last case it is of course a question whether the thickened ulcer found at the pylorus at the operation was already malignant, but the absolutely good health enjoyed by the patient for eighteen months leads me to consider that the carcinoma was of more recent origin. I have been unable to trace 17 of my cases, no replies having been received to my letters of inquiry.

Out of 81 cases which I have traced, 5 have since died, and I have divided the remaining 76 cases into 5 groups.

In the first group the result is absolutely satisfactory, the patients feel better than they ever did; the following answer to my inquiry expresses the condition of a patient four years after a gastro-enterostomy: "I have no complaint to make; no sickness, no pains; eat and drink well. Many thanks!" In this group I have put 46 cases, or 55 per cent. of the cases which could be traced.

In the second group I place patients whose general

health is almost perfect, but who are liable to attacks of vomiting (nearly always bilious) which occur at irregular intervals. The vomiting often comes on after a chill, and is not dependent on any error of diet; directly the vomiting ceases they feel quite well again, and at other times can eat or drink anything. The explanation of this condition is that it is either caused by a chill, or by a temporary twist in the jejunum just below the anastomosis. In the same group are included cases who occasionally suffer pain after food, such pain not being severe and not depending on any error of diet. In some cases I have suspected the presence of adhesions as the cause, and in others I have suspected a neurotic element. In one case in which I suspected adhesions, the pain ceased after several injections of fibrolysin. In this group I have placed 21 cases, or 26.5 per cent. of the cases which could be traced.

In the third group I place cases who consider that they have derived benefit from the operation, but who still have occasional pain and vomiting, and whose general health is not much improved. In this class I am glad to say that there are only 5 cases.

In the fourth group I place two cases in which the results have been unsatisfactory, but who are still under treatment. In both these cases the pain and vomiting recurred within a couple of months of the operation, and an occlusion of the pylorus was performed in each case six months later; in one case this completely cured the stomach symptoms, in the other the vomiting recurred as soon as the patient got up. The case in which the stomach symptoms were cured suffered severe pain over the caecum, and the ascending colon became dilated; at a subsequent operation a band was found pulling on and obstructing the transverse colon. All pain ceased after division of the band, but the case is still under treatment. In the second case, in which the pain and vomiting recurred after the occlusion of the pylorus, a subsequent operation revealed miliary tubercles scattered over the upper part of the small intestine, omentum, and parietal peritoneum.

In the fifth group I have placed two cases whose condition I consider unsatisfactory. Both cases had undergone stomach operations before coming under my care, and in both I suspect that a wrong diagnosis was made in the first instance, and that they were cases not of gastric ulcer but of nervous dyspepsia. One case has had three operations, and is as bad as ever; the other has had seven operations, after each of which she has been apparently cured for two months, and then the pain and vomiting have returned. In addition to these two last groups of unsatisfactory cases, I ought to tell you that five other cases at first were not satisfactory, but these have been cured by a secondary operation.

I have not made any attempt to conceal any of the unsatisfactory results after gastro-enterostomy, as I wish to lay the case for the operation fairly before you. The successes amount to about 85 per cent. and the failures to about 10 per cent. This is a most satisfactory position.

Some of the earlier cases of incomplete cure have undoubtedly been due to imperfection in the technique of the operation, and the results of future cases are likely to be much more satisfactory. In my early cases, a loop of jejunum was left between the duodenum and the gastro-enterostomy opening, this in 4 cases was the cause of bilious vomiting, which was cured by an entero-anastomosis, and it may account for the occasional vomiting observed in other cases. I now always perform the so-called "no loop" operation in which the jejunum is attached to the stomach as close as possible to its commencement, so that the tendency to bilious vomiting is reduced to a minimum. Again, in the early cases the pylorus was never divided or occluded at the time of the gastro-enterostomy, with the consequence that in cases where there was no cicatricial stenosis of the pylorus the gastro-enterostomy has ceased to be of any use. I now make it a practice to occlude the pylorus in every case of gastro-enterostomy where the ulcer is situated at any distance from the pylorus or in the duodenum. I have occluded the pylorus as a secondary operation in four cases, in two of which the result was completely satisfactory.

Some years ago I was inclined to consider that gastro-enterostomy was a specific for every disease of the stomach, and I performed the operation in some cases of simple long-continued gastritis with spasm of the

pylorus; these, however, I do not consider suitable cases for operation, and should be left to the physician. I now never do a gastro-enterostomy unless an ulcer or the cicatrix of an ulcer can be found in the stomach or in the duodenum, and if I undertake an operation under a mistaken diagnosis of ulcer and I fail to find an ulcer or any disease in the neighbouring organs, especially the gall bladder, I close the abdomen.

The most brilliantly successful cases undoubtedly are operations for cicatricial contraction of the pylorus, but in my opinion it is not wise to allow patients to wait for operation till well marked stenosis has occurred, with its accompanying dangers of extreme dilatation and food decomposition. Such delay may reduce the patient's strength so greatly before operation that the prospect of recovery is lessened. This was the case in 3 cases which ended fatally, and in 2 others which died within a few months of their return home.

A certain number of cases of gastric ulcer have other morbid conditions associated with the ulcer. The most frequent associated disease in my cases has been floating kidney, which existed in 6 cases: in 1 case the operation of nephrorrhaphy was done at the same time as the gastro-enterostomy, and in 3 cases it was performed on subsequent occasions; in 2 cases no operation has been done for the floating kidney. Gall stones were present in 1 case, and cholecystectomy was performed. Lastly, appendix adhesions existed in 3 cases, and in 2 cases the appendix has been removed at a subsequent operation.

With regard to the indications for the operation of gastro-enterostomy, I consider that it should be performed in every case of chronic gastric ulcer which has resisted medical treatment, or which has recurred after it. In forming the diagnosis of a gastric ulcer with a view to operation, I consider the following points are the most valuable: The existence of a tender spot at a fixed point in the epigastrium, pain after food with or without vomiting, the history of hæmatemesis or melæna, especially when this is repeated constantly; the presence of free hydrochloric acid in the stomach contents; and, lastly, evidence of some dilatation of the stomach. I make a rule of passing a stomach tube in every case and withdrawing some of the stomach contents for chemical examination; after this I distend the stomach with air through the tube. Excluding cases of gastroparesis, I consider that a stomach which extends one or two inches below the umbilicus is dilated.

The presence of dilatation is an absolute indication for gastro-enterostomy.

The operation is also indicated in every case of duodenal ulcer as soon as it can be diagnosed, as practically no case of duodenal ulcer is permanently cured by medical means, and a temporary improvement under medical treatment may be followed by fatal hæmorrhage or by perforation. The difficulty here is to make an accurate diagnosis of a duodenal ulcer. The most valuable signs are the presence of a tender spot just above and to the right of the umbilicus, sometimes accompanied by rigidity of the right rectus muscle; the existence of "hunger pain," which sometimes necessitates the patient always carrying food with him; pain following some hours after food; the presence of melæna and of unexplained anaemia.

In acute gastric ulcer the indications for operation are repeated severe hæmorrhages, which are threatening the patient's life; and, secondly, symptoms of acute pain and shock, suggesting that the ulcer is spreading deeply towards the visceral peritoneum, and that perforation is imminent.

I believe that an ulcer in any part of stomach or duodenum can be cured by gastro-enterostomy; but if the pylorus is not stenosed it must be occluded at the same time, otherwise the results are not likely to be permanent.

In estimating the value of gastro-enterostomy in gastric and duodenal ulcer, we ought to compare the results with those obtained by medical treatment. Most surgical writers are rather scornful of the results of medical treatment, and recently it has been stated that barely 25 per cent. of cases of gastric ulcer are cured by medical treatment. I think that such statements are grossly unjust and misleading, since they are compiled from records of hospital in-patients, and therefore deal only with the most severe cases of ulcer; moreover, they

include deaths from hæmorrhage and from perforation. Now the greater number of cases of gastric ulcer are treated as out-patients, and their mortality cannot be large, but there are certainly a number of relapses. I suppose that even the most sanguine physician would expect relapses in at least half his cases of gastric or duodenal ulcer, and so would not expect one-half of his cases to be permanently cured; I think that even my statistics show a great improvement over medical treatment, since 56 per cent. were absolutely cured and another 26 per cent. were in almost perfect health.

The knowledge that the greater number of patients on whom the operation has been done are delighted with their present condition and have practically been restored to complete health after years of suffering consoles one for the few cases which appear to derive little benefit, and enables a surgeon to honestly advise a patient with marked symptoms of chronic gastric or duodenal ulcer to submit to a gastro-enterostomy when medical treatment has failed to effect a cure.

A Clinical Lecture ON THE TREATMENT OF ACUTE APPENDICITIS.

DELIVERED TO THE 1908 POST-GRADUATE CLASS AT
ST. BARTHOLOMEW'S HOSPITAL.

BY R. COZENS BAILEY, M.S. LOND.,
ASSISTANT SURGEON TO THE HOSPITAL.

I AM constantly being asked, "Do you believe in operating during the acute stage of appendicitis?" and I propose to attempt to answer this question.

I have chosen this subject partly because I shall be able to show you cases in the wards at the present time which illustrate many of the points we shall have to consider, and partly because the idea seems to have gained ground that it is old-fashioned to wait, and that the newest and most up-to-date practice in connexion with the surgery of appendicitis is to treat the case as if it were, say, a strangulated hernia, and to operate always when and where an opportunity first presents—an idea which I can only regard as most mischievous. Appendicitis seems to have become more common and more fatal of recent years, and this rightly suggests all sorts of questions as to our altered manner of life, our increased luxuriousness, the quality and quantity of our food and drink, our possibly diminished resistance to the onslaught of micro-organisms, or the increased virulence of these. It also suggests the question, Can our better diagnostic powers have anything to do with the one fact, and our methods of treatment with the other?

One of the chief difficulties in connexion with appendicitis arises from the number of different conditions included under the term. Thus not only do inflammation and ulceration find a place under this head, but also perforation, gangrene from infection or thrombosis, impaction of foreign bodies, the formation of concretions, stricture, etc., and it need hardly be pointed out what confusion would arise if in other parts of the intestine the term "enteritis" was used to cover all these.

I can only mention this source of error but cannot suggest a remedy at present, for the appendix is such a comparatively unimportant structure physiologically, that interference with its functions in these ways gives rise to few distinctive symptoms, and its importance, from a surgical point of view, depends almost entirely upon the results it is able to produce in connexion with the surrounding peritoneum. It may be that further experience and the more accurate tabulation of symptoms will one day render it possible to diagnose more certainly the state of the appendix upon which the resulting peritonitis depends, and so enable a more exact prognosis to be given, and thus render easier the question of treatment; but at the present time the beginning of the attack affords little or no indication as to what will be its end.

Now, if the appendix be damaged the infection may remain confined to the interior of the organ and its walls,

or may spread to the surrounding peritoneum. In the latter case the results depend chiefly upon the virulence of the infecting agent, the resisting power of the peritoneum, the amount of infective matter with which it has to deal, and the area of its surface infected. Thus there may arise:

- (a) A plastic peritonitis.
- (b) A spreading suppurative peritonitis.
- (c) A general suppurative peritonitis.
- (d) A localized suppurative peritonitis—that is, an abscess.

(a) Although it is a question whether such a thing as capsular appendicitis is possible—and it has been stated that the onset of symptoms of appendicitis always denotes that peritonitis has occurred—I have no doubt that on the one hand the trouble may be practically confined to the interior of the appendix and its walls, and on the other that the few adhesions which sometimes remain after an attack has cleared up are no indication either of the intensity or area of the infection at the time.

(b) This condition is often very difficult to diagnose, and it is in connexion with it, I believe, that mistakes in treatment are most likely to occur. In its typical form it complicates gangrene of the appendix or slow perforation, and spreads either as a lymphangitis or by extension throughout the peritoneal cavity, the purulent fluid not being shut off by adhesions, or, owing to the virulence of the infection, if adhesions do form, they are of the flimsiest character, and form only to melt away again.

The inflammation will radiate from the appendix, and so its starting point will depend upon the position of that structure; and it is no uncommon occurrence, when this is in the pelvis, to find that cavity full of a thin purulent fluid, scarcely shut off from the abdominal cavity by floating intestines, loosely held together by a sticky lymph, not sufficiently dense to constitute the wall of an abscess; and yet it is obvious that the abdominal peritoneum is not taking part in a suppurative inflammation, though possibly congested and containing a quantity of serous fluid.

The difficulty in diagnosing this condition lies in the fact that, though a localized suppuration, it is not sufficiently shut off to form a definite abscess, and though general often as far as the pelvis is concerned, it is not sufficiently widespread to give rise to the symptoms of a general peritonitis.

(c) General suppurative peritonitis comes on at different stages of the illness according to its cause.

If due to perforation or rupture of a free-lying appendix, with immediate wide extravasation of its contents, it is an early complication, showing signs of its presence in the first few hours after a longer or shorter interval of collapse, just as with perforations of the stomach or intestines.

In other cases a spreading peritonitis, as described above, may end by becoming universal: in which case the onset of general symptoms is more insidious and later, from the second to the third or fourth day.

It may sometimes, though rarely, be due to the bursting of an abscess, in which case it practically never occurs before the tenth day.

(d) Although, as mentioned above, a collection of pus may be localized in a portion of the peritoneum, a cavity with walls sufficiently dense to merit the name of an abscess can hardly occur before the fifth or sixth day. If any object to this distinction, I can only say that I regard it as most essential to differentiate, in some way or other, between the early collection of pus which will spread, and the later-formed one which will not.

Now the treatment of a case of acute appendicitis has for its object the prevention or alleviation of one or other of the above complications, and I cannot express the opinion too strongly that the treatment necessary must depend upon the stage the illness has reached, upon the time at which the patient is first seen; and that it is wrong to lay down a general rule that all such cases should or should not be operated on at once.

There are cases, of course, in which premonitory symptoms may warn a careful observer of what is taking place inside the appendix, and in these the organ may well be removed as a truly preventive measure; just as, for instance, the presence of gall stones within the gall-bladder

may be diagnosed before an actual attack of colic has occurred.

With such, or with those in which there has been a previous attack, I am not at present concerned, but with those in which the patient is struck down without previous warning, and with all the suddenness of a bolt from the blue.

Let us assume, and I admit it is a big assumption, and your own experience will confirm me when I say it is seldom indeed that such a combination of circumstances will exist—let us assume that you have been called to see a patient directly after he has been attacked, that the case is undoubtedly one of appendicitis, and all other causes of abdominal pain and stomach-ache can at once be definitely excluded; that the patient is in a good state to take an anaesthetic; that surgeon, anaesthetist, and nurses are all at hand, and that the arrangements for an immediate operation can be carried out; then I believe that such a course is a wise one.

If in any given case one could be sure that a plastic peritonitis only would result, I imagine there is no one who would not counsel, postponing operation until after the inflammation had subsided; but it is because one cannot tell whether or not one of the more severe complications will arise that an immediate operation becomes advisable.

At this time in every kind of case save one the mischief will still be confined to the appendix, and so the local conditions will be favourable for operation; and in the one class of case where the trouble will have spread already to the peritoneum (the so-called fulminating cases due to perforation or rupture of the appendix) no better time for surgical interference could be chosen.

My own experience of such events is limited to a few cases in hospital, where alone the combination of circumstances we have assumed is likely to occur; and I would lay it down as a rule that it is justifiable, and may be wise, to advise operation in all cases at the beginning of an attack of acute appendicitis, if—and there's the rub—if it can be done.

This early period having been missed, as in the great majority of cases it will be missed, operations should only be undertaken because one of the severe peritoneal complications has arisen. Of course, I don't mean to say that a series of successful operations may not be performed at a later stage than I have indicated, but every hour that is allowed to elapse renders surgical interference less and less advisable. For as the inflammation spreads the parts become most vascular and oedematous, adhesions which ooze blood at the slightest touch rapidly form, the engorged intestines bulge with stagnant flatus, micro-organisms swarm in the swollen and turgid tissues, and altogether at about the end of the first twenty-four hours it is impossible to imagine a local condition more unfavourable for an operation. This state of affairs seen by the limited view which alone is possible through an incision in the right iliac region may mislead even the honest statistician, when compiling his mortality tables, by giving the false impression that a general peritonitis already existed. And, worse still, the necessary manipulations which an operation entails may set up the very trouble which it had been undertaken to prevent, by diffusing the septic material so that a general peritonitis results, when probably if left alone the inflammation would have localized and at the worst an abscess have formed, but not necessarily even that. I admit that the dangers have been exaggerated, but nevertheless I know that they exist; and even where no fatal result ensues and the case is scored as a surgical success, such success may only be gained at the expense of a drainage tube, a suppurating wound with a weak abdominal wall, a hernia, and a second operation for its cure. A success indeed if death were the only alternative. But it must ever be borne in mind that the great majority of cases recover spontaneously, temporarily, at any rate, and therefore can be operated on more favourably at a later period; and that operation at this stage can only be advised to benefit the unknown minority in whom fatal peritoneal complications will ensue. The rights of this minority must depend upon its size, and I feel sure that the surgeon who recommends preventive operations at this stage exaggerates its proportions; and the more he operates the more he will be inclined so to do. There is no surgeon of any degree of

experience who will not be able to recall not one but many instances in which, when performing appendicectomy during the quiescent stage, he has found evidence of the gravest former trouble. Adhesions so universal that only a general peritonitis could account for; a truncated appendix whose condition nothing but sloughing or gangrene could have produced; inspissated secretion which showed clearly where a former abscess had been absorbed.

Though no one would trust for a moment to the *vis medicatrix Naturae* rather than to the surgeon's knife when actually confronted with any one of these, still cases of spontaneous recovery from the worst conditions occur in sufficient numbers to make us pause when estimating the risks of an operation undertaken to prevent their onset, especially when the odds are against that taking place.

I hold strongly, therefore, that at the time at which most cases of appendicitis will be seen it will be wrong to recommend an operation as a preventive measure. Complications will require to be met after they have arisen, and at this period it will only be necessary to exclude perforation or rupture of the appendix before deciding to rely upon medical measures.

Perforation of the appendix gives rise to the characteristic train of symptoms with which you are familiar in connexion with a similar accident to other parts of the intestinal tract.

The sudden severe onset of violent cramp-like pain, chiefly over the lower abdomen and in the region of the umbilicus, and intense localized tenderness with collapse (shown by the cold extremities, the subnormal temperature, the frequent, small, tensionless pulse, and cold perspirations), accompanied by extreme local rigidity, probably of the lower part of the right rectus muscle, with general hardness, immobility and retraction of the abdomen, will at once indicate that perforation of some viscus has occurred, and the position of the tenderness and rigidity will point to the appendix. If you see the patient at this stage you will have no doubt as to the proper course to pursue.

I would have you note that at this period the symptoms are those of abdominal shock, and though, of course, a certain amount of inflammation is early set up, general peritonitis with its equally impressive picture has not yet had time to supervene. When it has, the pain and tenderness become general, though still greater probably in the right iliac fossa; the temperature rises; the pulse, still frequent and small, acquires a degree of tension above the normal; the immobility of the abdomen remains, the local rigidity is marked by the general hardness, and retraction gives place to distension. Vomiting, which may or may not have occurred in the beginning, now is almost constantly present, and of a diagnostic character, namely, the frequent regurgitation without effort of small quantities from the stomach and upper part of the small intestine. Gaseous eructations frequently occur, but, owing to paralysis of the intestinal musculature, no flatus is passed per anum. The tongue becomes dry, and the face assumes its characteristic sunken, drawn, anxious expression. Again, if called to see the patient at this stage, you will not be in doubt. There is, however, a time when the collapse is passing off, and the symptoms of general peritonitis have not yet acquired their characteristic features, when the diagnosis may present difficulties; but even now the look of profound illness which the patient wears will indicate the urgency of the mischief; and though all other signs may be equivocal, the contracted abdominal muscles are never completely relaxed, and the frequency of the pulse will still remain. A slow pulse with a temperature about the normal, in my experience, is not met with in the early stages of general suppurative peritonitis, but when it occurs is an indication of the approaching end, the patient being so poisoned with toxic products that his tissues no longer react. A mistake in diagnosis may be made now, but as the case is practically hopeless by this time, its importance is not so great.

Having now decided that the time for a preventive operation has gone by, and that the patient is not suffering from a perforation, you may dismiss the question of operation from your mind, for the present.

The patient should be placed in bed on his right side with the shoulders raised in order that gravity may assist in preventing the diffusion of any fluid which may collect. Hot fomentations relieve pain, and are further useful in

bringing about an active local hyperaemia. Salt solution per rectum relieves thirst, and also acts beneficially by setting up an increased leucocytosis. Food by the mouth should be withheld, although I am convinced that most of the evils attributed to its administration in liquid form arise from the mistaken notion that milk is not a solid diet. It is an unnecessary cruelty to forbid all liquid, because in small, frequent doses it does no harm, in that it is absorbed long before it reaches the intestine in the neighbourhood of the inflamed part. And though the introduction of liquid into the rectum is a fairly efficient substitute, if this route be chosen on peristaltic grounds, it should be borne in mind that, granted peristalsis is harmful, it is as likely, and perhaps more likely in the case of the larger intestine, to be excited by the introduction of fluid by the anus as by the mouth. But is peristalsis harmful? I think not, but just the reverse.

If the peristaltic wave produced a violent commotion among the intestines, dashing them about, or even more gently transferring them from one place to another, then, of course, it would have to be avoided at all costs. But a regular peristaltic wave being but a gentle ripple on the surface, incapable of moving the bowel as a whole, but only able to produce an onward movement of the intestinal contents, and incidentally to favour the circulation of the blood and lymph in the intestinal vessels, can only be beneficial, and must produce less disturbance than the distension of the bowel by accumulated gas, etc., which necessarily results if peristalsis is absent; and I am so struck with the favourable termination of most cases which begin with diarrhoea that I do not hesitate to order a laxative at this stage if required, preferring small doses of calomel to anything else. Purgatives should be avoided, not on account of the peristalsis which they set up, but on account of the contraction of the abdominal muscles which is likely to attend their action. If peristalsis were, indeed, harmful, then not only should nothing be done to increase it, but it should be prevented altogether, and thus the long discredited treatment by opium be reintroduced.

Under the treatment outlined above the majority of cases will show signs of improvement, but this will be gradual, and from the second to the fourth day, even in those cases which eventually recover without suppuration, the patient may still show signs of a severe local peritonitis.

It is at this stage that the operating surgeon is so frequently called in with a view to opening the abdomen, and I must repeat, even at the risk of wearying you, that the time for a preventive appendicectomy has passed; that the harmless little exploratory incision in the right iliac region, when the offending organ may be down in the pelvis or up under the liver, is a delusion and a snare; that probably the peritoneum has fought its fight, and has won the battle, if the surrounded hosts of dying micro-organisms are not carried into fresh fields, and supplied with fresh food and vitality by the escape of blood which an operation will cause. That even under these circumstances victory will still generally rest with the peritoneum is nothing to the credit of the operation; but should victory be turned into defeat, operative interference (and the word possesses a sinister significance) cannot escape the blame.

No! at this stage, if the peritonitis is localizing, operation can do nothing but harm, and it is only if a spreading peritonitis is in evidence that the immediate opening of the abdomen becomes necessary. The onset of this is insidious and its detection not without difficulties. But it is so important to recognize what is taking place at an early period that I feel I must go a little more into detail with regard to the symptoms which enable a diagnosis to be made.

The temperature and pulse are misleading in so many instances that I have come to ignore them, but if the frequency of the latter keeps persistently over 100 with increased tension it should excite suspicion.

Persistent vomiting of small quantities without effort is almost diagnostic of a widespread affection of the peritoneum, and is of special import if it comes on again after the vomiting which ushered in the attack has subsided, or if it comes on for the first time after the disease has been in progress for some hours.

General contraction of the abdominal muscles is an important sign; but here I would warn you that you

must not expect the rigidity of a general peritonitis. In fact, palpation is an insufficient and unreliable means of detecting the condition. More information will be gained by inspection. Immobility of the abdomen and a consequent costal type of respiration will be seen, but, above all, attention should be directed to the contour of the muscles. I have known the visibility of the digitations of the external oblique afford an indication of the tonic spasm of the whole muscle, when this was insufficient to produce a hardness readily detectable by touch.

Constipation with flatulent distension is common enough in appendicitis, and means little; but when, perhaps in spite of laxatives and enemata, nothing, not even flatus, is passed, and the symptoms resemble those of intestinal obstruction, it may be inferred that an extensive peritonitis exists, giving rise to paralysis of a considerable length of intestine.

Sweating, often profuse, is another valuable sign that a large quantity of septic matter is being absorbed. It never occurs in uncomplicated cases of appendicitis, and at this period may always be taken to indicate a suppurative peritonitis.

The condition of the tongue may afford valuable help. True, it may remain moist and fairly clean throughout; but a dry, furred, foul state will suggest a grave condition.

Pain and tenderness in all cases, to start with, are generally referred to the whole of the lower part of the front abdominal wall, especially to the umbilical region; and then later only to the right iliac fossa. If, after this localization, the tender and painful area increases in extent, a spreading peritonitis is probable. But when, as is so often the case, the pelvic peritoneum is the part affected, no help can be derived from this sign. Extreme tenderness on rectal examination will be present, and the feeling with the finger of a bulging collection of fluid will at once reveal the nature of the case.

If cases of spreading peritonitis are diagnosed early, as they should be by proper attention to the above symptoms, and great care be taken to prevent diffusion of the fluid by careful packing after the abdomen has been opened; and if the disturbance of the parts be strictly limited to that which is necessary for the simple introduction of a drainage tube, the prognosis after operation is good—a fact again to be borne in mind when estimating the risks of a preventive operation.

We have now got to about the end of the fourth day, and with it nearly to the end of the dangerous period, for though late cases of spreading peritonitis may still occur, they are rare after this time.

And now the familiar, well-defined lump in the right iliac fossa can be readily felt instead of the indefinite hardness. This is a welcome sign, as it indicates a matting together of the intestines by strong adhesions, and a definite circumscription of the trouble.

Flatulent distension is still often a distressing symptom, and it is at this period again that laxatives are of great service. I would here repeat what I have previously said about the supposed dangers of exciting peristalsis.

A moderate dose of castor oil, combined with the use, if necessary, of the rectal tube and enemata of turpentine and asafetida, will often bring about, with the evacuation of the intestinal contents, such a marked change in the iliac swelling that what appeared to be an inevitable abscess rapidly disappears, accompanied by a fall in the temperature and a subsidence of other unfavourable symptoms little short of surprising.

From this point convalescence may date or an abscess may form. In the latter event the symptoms follow two courses. In the one the temperature and pulse come down, and the local symptoms somewhat subside; but after an interval, ranging from a few hours to a day, the temperature gradually rises again and the pulse increases in frequency, until both may stand as high as or higher than before. The local signs again become more marked; the lump increases in size and distinctness, pain is worse and of a throbbing character, tenderness even on slight pressure again becomes acute, vomiting and sweating may occur, and the tongue becomes dry and furred. In the other the inflammation runs on to abscess formation without any intermission. In such a persistence of acute symptoms on the fifth day practically always means that suppuration has occurred.

The subject of an increased leucocytosis in connexion

with the diagnosis of suppuration is much too large for me to enter into here, but I would say, in passing, that too much importance must not be attached to it. One total count, though high, is of little significance unless confirmed by subsequent readings. A differential count may afford more valuable information.

When localized suppuration has taken place an operation will probably be necessary. But here again it is a mistake to think that in all cases it must be done at once; in fact, I would go further and say in the majority of cases it is best to wait for a time. If the patient be kept quiet, bursting of an abscess is practically unknown at this period; and remote sequelae, such as portal pyæmia, rarely complicate abscess formation, and at any rate their onset is not favoured by reasonable delay. Against these theoretical disadvantages may be set the solid gains—that the abscess will become firmly shut off, its walls well defined and possibly adherent to the abdominal wall, so that the evacuation of its contents is greatly simplified; that the pus will decrease in virulence, or even become sterile; and that in some few cases operation will not be required, owing to the escape of pus into the bowel or its absorption. A certain amount of discrimination is of course necessary, but generally it may be said that those cases in which the symptoms have persisted acutely from the beginning will require an earlier operation than those in which an intermission has taken place.

And now let me add just a word or two about the removal of the appendix. If general peritonitis is present this should always be done, provided it does not add greatly to the length of the operation; if the peritonitis is local, never, unless the organ presents on opening the abdomen. In the case of a spreading peritonitis, even a limited search for it may break through the flimsy adhesions which are checking the spread of a virulent infection, and which will prove sufficient for the task once the pus has been given a free exit.

In the case of a definite abscess the risk is less. The greater density of the adhesions and the diminished virulence of the micro-organisms will generally allow the organ to be removed with impunity, but even so the immediate risk of the operation is increased. And in my experience the number of cases in which symptoms again supervene after once an abscess has formed and been evacuated is very small, less, considerably, than the 15 per cent. generally given. But, even taking these figures as correct, I am not prepared to submit 85 patients to an additional unnecessary risk, even if it were as slight as has been claimed, in order to benefit 15, especially as the benefit these latter derive is problematical, seeing that they might lose their appendices at a subsequent date with scarcely any risk at all.

In this connexion it is necessary to point out that the removal of an appendix after an abscess has healed is not necessarily a difficult operation. The adhesions left will disappear to a greater or less extent, so that the appendix may ultimately be freer even than when suppuration has not occurred, but the peritonitis has been of a plastic nature from the start.

Finally, if you have steered your patient through his first attack without operation, what course should you advise? Personally, I always recommend a patient not to run the risk of a second, but think it only fair to state at the same time that this may never occur, and that if it does it is likely to be no worse than the first, seeing that the majority of serious complications occur with a first attack.

If appendicectomy be decided upon, it is wise to allow an interval of at least three weeks to elapse from the cessation of acute symptoms in order that the local conditions may have time to clear up.

It is true that an aseptic operation may be done before this in most cases. But, having on more than one occasion met with an unsuspected abscess, which was obviously being absorbed, when tempted to operate at an earlier date, I have now fixed upon this period as a minimum.

The thirteenth Flemish Congress of Natural and Medical Science will meet at Brussels this year on September 18th, 19th, and 20th. One day will be devoted to the discussion of the diagnosis and treatment of syphilis. The discussion will be opened by Drs. Bayet and Behaegel.

A Clinical Lecture

RESECTION OF THE CAECUM FOR CANCER OF THE ILEO-CAECAL VALVE.

DELIVERED AT ST. BARTHOLOMEW'S HOSPITAL.

BY HARRISON CRIPPS, F.R.C.S.,

SENIOR SURGEON.

GENTLEMEN.—In a recent lecture I gave you a short account of the symptoms and treatment of rectal cancer. To-day I have a good opportunity of saying something about the same disease in the opposite end of the colon, for on the table before you are three caeca resected for cancer of the ileo-caecal valve. All the operations were done during the same week, which shows that the disease is not uncommon.

For the following notes I am indebted to my house-surgeon, Mr. Hoskyn.

CASE I.

W. B., aged 63, clerk. Admitted into the hospital November, 1908, complaining of pain in the abdomen since September. He has had two or three attacks of diarrhoea, but after these has gone some days without any motion. The diarrhoea was preceded and accompanied by violent vomiting. He has never passed any blood or mucus. He is a sallow-looking man with a large and full abdomen. Has lost weight recently. On the first examination no tumour could be felt. A few days later a tumour the size of an egg was detected 1 in. above and to the right of the umbilicus. The tumour was very mobile. Some days it could be easily felt, at other times the most careful palpation failed to detect it. It seemed to disappear under the ribs.

Operation.—November 16th. A 5 in. incision along the outer border of the right rectus. On opening the abdomen a small amount of free fluid escaped. On introducing the hand a tumour was at once felt, freely movable, and it could be pushed several inches in any direction. The edge of the omentum was adherent to it. It proved to be a hard malignant adenoid growth, spreading like a thick ring all round the valve and projecting into the caecum. The growth extended up to but not through the peritoneal coat. The caecum was excised, with about 2 in. of the ileum on one side and the same amount of the ascending colon on the other. An end-to-end anastomosis was made, great care being taken to unite the mesenteric attachments. The patient convalesced without trouble, rapidly gained weight, and left the hospital in five weeks. March, 1909; Patient is still in good health, and walks ten miles a day.

CASE II.

W. C., aged 67, sorter in the G.P.O. Transferred by Dr. Norman Moore to the care of Mr. Harrison Cripps in November, 1908. For the last nine months has been troubled with intermittent diarrhoea, with occasional constipation. For the last few months has had some intermittent pain about the umbilicus. Has lost flesh rapidly. No definite tumour could be felt by palpation until he was put under an anaesthetic, when a tumour could be clearly felt situated deeply in the right iliac fossa.

Operation.—November 23rd. On opening the abdomen the caecum was found to be the seat of a new growth involving the valve and a considerable portion of the caecum itself. In the mesenteric attachment two or three glands the size of nuts could be felt, but the finger and thumb could grasp the membrane well beyond them. The whole caecum was removed, with 2 in. of the ileum and 4 in. of the ascending colon, an end-to-end anastomosis completing the operation. The patient did well till the third day: he then died quite suddenly without any warning, sitting up in bed and expiring in a few minutes. At the post-mortem examination there was no sign of anything wrong in the abdomen. The anastomosis was perfect, showing no leakage with high water pressure. A careful examination was made for a pulmonary clot, but none was found.

CASE III.

Mr. —, aged 54, sent to me by Dr. Cayley with the following history: Has always been a most active and healthy man and indeed feels perfectly strong and well at the present moment, with the exception that once or twice lately he has had a sudden sharp pain in the abdomen. The bowels are quite regular. On two occasions in the last three months he has passed blood, dark in colour, and to the amount of a few teaspoonfuls. He also passed one day after a rapid walk "a small mass of tesh the size of the end of his finger which did not dissolve in water." On palpation nothing could be felt in the abdomen. Under an anaesthetic by bimanual examination a swelling could be felt high up in the pelvis, but not sufficiently distinct to enable a diagnosis to be made. An exploration was advised.

Operation.—On opening the abdomen by a 5 in. incision in the middle line and introducing the hand, a hard tumour could be felt the size of an egg lying in the pelvis at a level with the summit of the bladder. It was adherent and could not at first be drawn up. However, after separating some slight adhesions with the finger-tips the tumour was freed and suddenly came out of the pelvis right up into the wound. It was then found to be the caecum containing a cancerous growth surrounding the valve. The whole thickness of caecum in about half its diameter being involved. The growth was excised with a very free margin of healthy tissue, the cut bowel being joined end to end, the length of the excised portion being 8 in. The patient had no trouble and returned home at the end of a month, and has since remained in perfect health.

PATHOLOGY.

In the vast majority of cases malignant disease in any part of the large intestine is of the adenoid variety. It is essentially a growth starting in the mucous membrane, extending from hence into the submucous and muscular coats. It is only late in the disease that the glands are affected, and eventually the liver and other organs.

Fig. 1 is a section taken from the heaped-up margin of the tumour projecting into the lumen of the bowel. It shows an irregular glandular structure of the involuted type, like Lieberkuhn's follicles. Fig. 2 is a cross-section at point A in Fig. 1 under a higher power. What appears to be the epithelium lining a follicle is, of course, merely an invagination of the epithelium from the growing surface.

If the tumour grows entirely into the lumen of the bowel with a pedicle, it

forms an innocent polypus. If, on the other hand, instead of growing free into the bowel cavity, it grows downwards into the muscular coats, it spreads along and through them and becomes malignant.

Microscopically there is no difference in structure between an innocent polypus and malignant disease. It is a question of the direction in which the follicles grow. If growth takes place from the summit of a follicle, it soon becomes pedunculated and forms a beautiful tree-like structure, standing out bold and free, like an oak in a park. Such growths may slowly increase to the size of a tennis ball, forming a villous tumour, which may remain innocent for years, and will not recur after removal.

On the other hand, should the growth start from the base of a follicle, it will spread widely into and along the muscular coats and ultimately through them into neighbouring tissues, showing all the characteristics of malignant disease.

Although the great majority of papillomatous and villous tumours remain innocent throughout their career, I have seen and recorded cases in which such growths, after remaining innocent for years, suddenly commence to grow downwards, developing all the characteristics of cancer.

An important fact about cancerous growths in the intestines is that they are less malignant than cancer in many other parts of the body. If left alone, however, I have never known a case in which life has not ultimately been destroyed. On the other hand, if completely removed

FIG. 1.—Section of adenoid cancer of the large intestine, taken from the spreading margin invading the mucous membrane. Low power.

before they have extended through the coats of the bowel, the results are often most satisfactory. I have had quite a fair number of cases of resection of portions of the bowel for cancer which have shown no sign of recurrence after intervals of ten to twenty years.

SYMPTOMS.

Seeing that success mainly depends on removing the growth before it has perforated through the bowel coats, an early recognition of the symptoms is of the utmost importance. If in the rectum and within reach of the finger the diagnosis is easy, but if high up in the rectum or in any part of the colon the detection of a growth is much more difficult. The higher up the bowel the less are the symptoms; indeed, when high up the colon or in the ileo-caecal valve the onset of complete obstruction may be the first indication of anything seriously wrong.

When low down, as in the rectum, the symptoms are more suggestive. At first the bowels act two or three times a day at odd times. As the disease advances the calls to the closet become very frequent—anything from half a dozen to a dozen times a day. The patient on going to stool does not pass a real motion; more often it is only a few teaspoonfuls of mucus, dark by a mixture of motions and blood. Occasionally there is some bleeding

without any motion with it. This is more commonly present in an early than in a late stage. The patient is troubled with wind, which he does not like to pass for fear of a mishap into his small clothes. When the sigmoid is affected the symptoms are much the same as in the rectum, but not nearly so pronounced. There is seldom any actual pain at the seat of disease, merely slight colicky discomfort from time to time all over the abdomen. Again, when in the colon, the constant desire to go to the closet is often absent, and there is less discharge. The reason of this is doubtless explained by the different habits of the rectum and colon. The latter objects very little to the accumulation of faeces within it; indeed, this is part of its function. On the other hand, the rectum resents anything being retained, and always has the desire to expel it.

In the 3 cases recorded the general symptoms were slight and not such as to suggest the patients were suffering from so fatal a disease as cancer. In Case III, when the operation showed a considerable mass of growth, the opening through which would scarcely admit the little finger, the symptoms were so slight that the patient described himself as feeling in perfect health, with the exception of occasional gripping pains, and it was only because he noticed some blood that he sought advice. In any case, when the possibility of a growth in the colon is suspected yet nothing can be felt definitely by ordinary palpation, a thorough examination of the abdomen should be made under an anaesthetic. The assistance given by complete relaxation of the muscles is invaluable. In Cases II and III it was only after such an examination that a definite tumour could be felt, and the grounds for an exploratory operation with a view to removal of the growth justifiable.

THE OPERATION.

In resecting portions of the intestine, it seems to me a mistake to remove a V-shaped piece of the mesentery as generally recommended. It is obviously important that the blood supply should be as good as possible right up to the cut edges of the bowel. The entire blood supply

comes through the mesentery, the vessels anastomosing very freely just before they enter the bowel. No portion of the mesentery can be removed, therefore, without including some of the supply vessels. If instead of removing the V-shaped piece the attachment is divided close up to and parallel with the bowel, there is no risk of cutting off the blood supply except to the portion actually removed, and even this is utilized through the anastomosing circulation right up to the cut edges. In sewing the bowel together about one-fourth of its circumference lies between the two layers of the mesentery. It is this portion which requires the most accurate coaptation to get good union, as it is not peritoneal surface to peritoneal surface. To ensure accuracy this part of the circumference should be first united, the needle taking a good grasp of all the coats except the mucous membrane, only just the edges of which are included. The sutures (No. 00 silk) are tied so that the knot lies within the bowel. The remaining circumference of the bowel is united by Lembert's sutures, the knots of which are, of course, tied on the outer surface. After the two rings of the bowel have been united, a few sutures should be passed so as to bring the mesenteric surfaces together and make them continuous with the gut.

As to the after-treatment, it is well for a few days to trust to rectal feeding. The alternate sutures in the abdominal wound can be removed on the ninth day, the remainder three or four days later.

Two of the cases recorded convalesced without any trouble, full motions being passed after the first week, and up to the present time both patients remain in good health. The death of the third patient was not explained by the *post-mortem* examination. Every thing within the abdominal cavity was found in complete order. Not a sign of peritonitis and the junction was firm and completely watertight under high pressure.

These sudden deaths a few days after abdominal sections must be familiar to every surgeon of large experience. Fortunately they are comparatively rare, but I have had three or four such cases in upwards

of 2,000 abdominal sections. The symptoms are all the same. A patient who is doing perfectly well, with a normal temperature and pulse, suddenly sits up in bed, turns an ashy grey colour, with a slight gasping for breath, and falls back dead in a few seconds. It is generally supposed that these sudden attacks are due to a clot in the pulmonary artery, but I can only say, though a careful *post-mortem* examination was made, no such clot was found in any of my cases, so that some further explanation of these tragic deaths is yet required.

PERFORATED DUODENAL ULCER TREATED BY SUTURE AND GASTRO-ENTEROSTOMY.

By W. PAYNTER NOALL, M.S.LOND., F.R.C.S.ENG.,
FORK.

I WAS asked to see the following case in consultation by Dr. J. R. Lawther on the evening of January 4th, 1909:

L. W. W., a man aged 44, who was on a visit to York, was suddenly seized on the previous midnight with intense abdominal pain, passing to the right side and top of the right shoulder.

History.

He had washed out his stomach the same day, and as he had taken nothing since, that organ was empty at the onset of the pain. He had eaten little for a week, and had taken only milk

and soda the two previous days. He stated that his health had been good till January, 1900, when pain came on after food at a regular interval of three hours, relieved by the next meal and also on the occasions he was sick. He also had acid eructations. On one night in October, 1900, the pain was severe. He vomited a large quantity of blood, had some loose black motions, and was a patient in a London hospital for three weeks.

From this date till June, 1904, every three months his symptoms would increase, the pain would be worse, he was constipated, had anorexia and loss of appetite, followed by vomiting, and relief with subsequent tarry motions. The vomit was sometimes black as well, but never alone.

From June to October, 1904, he could keep very little down; he consulted a physician, who told him he had a dilated stomach, and ordered him a special diet and lavage, which he had carried out up to the present. He remained in good health, exercising care in diet, till June, 1908, when he had a relapse of sickness and melaena, and also another in November, 1908.

When seen by me the patient was on his back; his expression was a little anxious and alert, the face pale and the tongue moist and slightly furred; he had a full pulse of 96 and the temperature was 99° F. There was no distension of the abdomen and the respiratory movements were present but their excursion diminished. There was some resistance over the upper part of the right rectus as well as tenderness (A) which extended downwards towards the appendix region. The liver dullness was diminished. The respirations were not hurried and there was normal vesicular breathing at the right base. On rectal examination no swelling or tenderness in Douglas's pouch was detected.

A diagnosis of perforation of a duodenal ulcer was made and an operation advised, consent to which was withheld till the next day.

Operation.

He was removed to the York Nursing Home, where, at 9.30 p.m., January 5th, a laparotomy was done, forty-two hours after perforation.

Under ether a vertical incision (B), 3½ in. long, was made through the upper part of the right rectus.

On opening the peritoneal cavity, a hissing escape of gas took place. Fluid, at first slightly turbid, with a few flakes of lymph, and then quite clear, welled up, and after mopping this up a cavity (shaded in figure) was exposed; it was lined with lymph, bounded above by the under surface of the liver and gall bladder and leading downwards and to the right as far as the appendix region. Separation of some adhesions between the commencement of the duodenum and the under surface of the liver revealed close to the pylorus a circular patch of lymph, the size of a sixpence, with a perforation ½ in. in diameter in its centre, situated on the upper and anterior surface of the first part of the duodenum. By retracting the liver and pylorus from one another, with some difficulty the perforation was infolded in a longitudinal direction with two rows of a continuous Lambert suture of celluloid thread. The stomach was filled with gas.

A posterior gastro-enterostomy was then performed, with the opening into the stomach made vertical, and the anastomosis with the jejunum as close to the duodeno-jejunal junction as possible, leaving no loop. The anastomosis was effected with two rows of celluloid thread, an inner one taking in all the coats of the stomach and jejunum, and an outer including the sero-muscular coats only.

The opening in the transverse mesocolon was sutured to the jejunum. Drainage was effected through a stab wound in the loin, and at the upper angle of the abdominal incision. Chronic catgut brought together the abdominal wall in layers, peritoneal musculo-aponeurotic, with additional supporting ones tied beneath the skin, and the skin edges with Michel's clips.

After-History.

The drainage tube and gauze were removed after thirty-six hours, and the clips on the fourth day. For the first twelve hours rectal salines were given, and after this feeding by mouth commenced. The pulse after the operation was 140; it fell to 100 the night after, and on the second night to 68. The bowels acted after an enema; physostigmine sulphate ½ grain was given hypodermically every two hours for four doses. There was no vomiting after the operation. In a month the patient left the home, having made an uninterrupted recovery.

As to his further progress, in answer to a letter of mine he wrote: "I have never had any pain or any sickness since I returned home from York. I can eat and drink practically anything now. My weight in overcoat was 10 st. 4 lb. about the middle of December last; now it is 11 st. 4 lb. in the same clothes. Every one tells me how well I look. After my past experience I can only say the sudden illness at York was really a great blessing in disguise."

In this case there was a nine years' history of ulcer; commencing with pain three hours after a meal, relieved

by the next meal, acid eructations, later haemorrhages, dilatation, intervals of good health under medical treatment, relapses, and finally perforation. Such a case may terminate in cancer, as a goodly percentage do.

Cases are on record where a duodenal ulcer and appendicitis have coexisted. The pain over the appendix in perforated duodenal ulcer can be explained on anatomical grounds. Maynard Smith¹ has shown experimentally that fluid escaping into the abdominal cavity through a perforation of the duodenum first fills up a cavity beneath the right lobe of the liver (the right kidney pouch), and then overflows, coursing downwards along the outer side of the ascending colon to the caecum. Hence the pain in this region.

Paterson² recommends gastro-enterostomy in all these cases if the patient can stand it, because it improves the after condition, lessens the risk where there is a second ulcer whether it has perforated or no, diminishes the risk of haemorrhage after operation, allows more efficient infolding of the ulcer, promotes more rapid and certain healing of the line of suture and so lessens the risk of further leakage, permits earlier feeding and earlier administration and more rapid action of purgatives, and so secures more efficient drainage of the peritoneal cavity.

The mortality depends mainly on three things: (1) Whether there is food in the stomach at the time of perforation; (2) the size of the perforation; (3) the time that has elapsed between perforation and operation.

In the case I record the stomach was empty, the perforation small (½ in.), and forty-two hours had elapsed between perforation and operation.

PERFORATED GASTRIC AND DUODENAL ULCERS TREATED SUCCESSFULLY WITHOUT SUTURE OF THE PERFORATION.

BY

EDRED M. CORNER, M.C., F.R.C.S.,

SURGEON TO THE CHILDREN'S HOSPITAL, GREAT ORMOND STREET;
SURGEON TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL, ETC.,

AND

WALTER BRISTOW, M.B., B.S. LOND.,

LATE HOUSE-SURGEON TO ST. THOMAS'S HOSPITAL.

WE bring forward these two cases because they both had simple convalescence, and in neither case was there any escape of food debris or any sign of gastric or duodenal fistula.

Both cases behaved as though the ulcers had been closed successfully—although this was not done—and, indeed, did just as well as successful cases in which we have sutured the ulcer. So much so, that it would seem that the time spent on unsuccessful attempts to suture a perforation may be wasted and militate against the patient's recovery—for speed of operating is undoubtedly one of the great essentials in bringing the treatment of peritoneal catastrophes to a successful conclusion. Every surgeon knows how often the stitches, inserted to close a perforation, cut through wholly or in part. If this occurs under his eyes, how often does it occur after the operation is finished? Indeed, many a case, treated successfully, in which the stitches closing the ulcers are thought to be secure, may be merely an example of what we have found—namely, if a perforation is merely "curtained" by omentum, recovery may ensue with no more troublesome convalescence than when the ulcer is closed.

The recovery after the non-suture of an ulcer shows how great a tendency there is in the material passing through a tube to flow along the tube, and not out of its sides. This is observable in the old method of performing colostomy when a lateral opening was made and the bowel not divided. In our cases there was no escape of digestive fluids although the perforation was merely "curtained." To prove that such a result does not always occur, even when the patients recover, it is merely necessary to quote

the case recorded by Mr. Roper, of Exeter, whose patient recovered with a gastric fistula and underwent some observations similar to those made in the famous case of Alexis St. Martin.¹

We would submit that our cases suggest that—

1. If stitches cut through at the operation, no further time should be wasted in trying to close a perforation.
2. That such a perforation be covered by omentum, anchored in place by one or two sutures.
3. That a gauze drain be conducted to the perforation and removed under an anaesthetic in forty-eight hours.
4. That the chance of recovery under this treatment is unlikely to be less than if the ulcer is sutured.
5. That the remote results of these cases, as regards pyloric obstruction, are no worse than when the ulcer is closed.

6. That in these, as in many other cases, a primary gastro-enterostomy is unnecessary for the recovery of the majority of cases.

CASE I.

G., female, single, aged 35, a patient of Dr. W. B. Winston of Bowes Park. History (September, 1906) of fourteen days' pain and tenderness in epigastrium, followed by signs of perforation; operation fifteen hours after perforation. A large perforation was found on the anterior wall of the stomach near the pyloric end and the lesser curvature. The surrounding stomach wall was thickened, sodden, and inflamed, rendering it impossible to sew up the perforation, as stitches would not hold. A tag of omentum was drawn over the perforation and arranged in position by two stitches. A gauze plug was arranged around. The peritoneal cavity was dry sponged through epigastric and suprapubic incisions and drainage tubes left in. At the end of forty-eight hours the plug was removed under chloroform by Dr. Winston. There was no escape of gastric contents. No food was given by mouth for twenty-four hours. At the end of twenty-four hours water was given for two days, and milk at the end of three days. The patient made an uninterrupted convalescence, and is very much better as a result of operation, at the end of two years showing no indication of any pyloric obstruction.

CASE II.

J. S., male, aged 29. Admitted to St. Thomas's Hospital August 6th, 1908; discharged September 9th. History of four months' pain after food, with vomiting. No haematemesis or melaena. A more than usually acute attack, lasting for five days, preceded the perforation. Operation fourteen hours after perforation. A large circular perforation, the size of a shilling, found at junction of first and second parts of duodenum, which it was impossible to close. A piece of omentum was anchored by two stitches over the perforation. A gauze drain was inserted. The peritoneal cavity, which contained a very large quantity of fluid and food contents, including some dozen or so French beans in a totally undigested condition, was dry sponged. When rendered as clean as possible by this method the peritoneal cavity was thoroughly washed out with hot normal saline. The operation was performed with all possible speed, and drainage used in both the epigastric and the suprapubic incisions. The gauze drains were removed in forty-eight hours under chloroform anaesthesia. Saline was administered per rectum for the first twenty-four hours. Water was given by mouth at the end of twenty-four hours. On the second day a rectal feed was given, and also saline per rectum, at six-hourly intervals. At the end of three days milk was given by the mouth in gradually increasing quantities, and on the sixth day a light diet containing custard, etc. August 17th: Signs were found at the left base indicating possibly a left subphrenic abscess. A transpleural exploration performed; no abscess found.

But for the rise of temperature and cough about this time the patient made an uninterrupted recovery, and was sent to a convalescent home on September 9th. He remains quite well, not suffering from indigestion or gastric trouble.

A CASE OF TRAUMATIC RUPTURE OF THE SIGMOID COLON: OPERATION: RECOVERY.

By WILLIAM SHEEN, M.S., F.R.C.S.,

STURGEON, CARDIFF INFIRMARY; CONSULTING SURGEON, ROYAL HAMADRYD SEAMEN'S HOSPITAL, CARDIFF.

Cases of traumatic rupture of the intestine are not common in the records of any one hospital. Series of cases collected by different observers afford much information about the condition. A recent paper by Berry and Ginseppi in the *Proceedings of the Royal Society of Medicine* for November, 1908, relates a case of recovery after operation, and gives an analysis of 132 cases which have occurred in ten London hospitals during the fifteen years, 1892-1907. This list is of more value than the lists of other authors

who have abstracted their cases from current literature, because cases of death and recovery are equally reported. I have drawn freely upon this paper in compiling the commentary which follows.

James R., aged 55, donkeyman, was admitted to the Royal Hamadryd Seamen's Hospital, Cardiff, on November 8th, 1908, at 9.30 p.m.

On the same day at 5 p.m. while moving at a rapid walk along the engine-room on board ship, he knocked the left side of his abdomen against the stationary handle of a reversing wheel. He had considerable pain for the moment, which passed off, and he continued his work for half an hour until he was relieved from duty. As he was going on deck he fainted, and the pain returned with great severity. Between 7 and 7.30 p.m. the bowels acted twice, but he does not remember passing any wind. A doctor saw him and advised his removal to hospital, where he was carried on a stretcher.

Condition on Admission.

The resident medical superintendent, Dr. J. H. Whelan, found that the pulse was 75 and the temperature 98.8° F.; the whole abdomen was tender on pressure, and its wall very hard. There was no distension, and no feeling of anything slightly drawn in. There was considerable general abdominal pain of a gripping character and tenderness and swelling over the right inguinal canal; 8 oz. of normal urine were drawn off. Sips of hot water and a hypodermic injection of morphine and atropine were ordered. He passed a good night, and next morning the abdomen seemed slightly softer; he had vomited several times—at first bile, then brownish non-odorous fluid. A little hot milk was ordered.

Operation.

On November 11th at noon I first saw the patient. The abdomen was exceedingly rigid all over, not distended, generally tender, and the seat of considerable general gripping pain. Over the left inguinal canal was a hard, tender swelling with some bruising. Sickness was frequent, the vomit being brown and non-odorous. No faeces or flatus had been passed since admission. The tongue was moist, the temperature normal, and the pulse good—96. The left lower part of the abdomen was indicated as the point where he had received the blow.

I operated immediately at 12.30 p.m., 43 hours after the injury. Dr. Cyril Lewis gave the anaesthesia and Dr. Whelan assisted. An incision was first made over the left inguinal canal, disclosing considerable effusion of blood and serum around the cord. This wound was closed. The abdomen was then opened in the middle line below the umbilicus. On opening the peritoneum, a small quantity of faecal-smelling, turbid fluid escaped, and there was universal acute peritonitis. Search for some time failed to reveal the cause of this, and the intestines had to be eviscerated under hot towels before a ragged-edged round hole about 1 in. in diameter was found in the sigmoid flexure, where it occupies the hollow of the iliac bone; particles of faecal matter were exuding through the hole. The hole was closed by a purse-string suture with a continuous Lembert suture over it, the abdomen was mopped out and irrigated with saline, and a faecal fistula established in the small intestine about 9 in. above the ileo-caecal valve, a large rubber tube being sewn into the bowel and anchored in the upper part of the wound. The rest of the wound was closed in layers, with catgut for the deeper parts and silkworm gut for the skin.

After-History.

The operation lasted rather over an hour, and the man's condition was bad at the end. He rallied somewhat under ordinary methods of stimulation, but vomiting and hiccough were frequent during the first twenty-four hours. He was given calomel (1 grain) hourly for five hours. During the night about half a drachm of fluid faeces came through the tube. The next day he was better, with normal temperature and pulse 98. The abdomen was flatter and softer. He occasionally passed dark green fluid. The calomel was repeated. On November 14th the bowels acted for the first time, five motions being passed per rectum. On the next day the bowels acted again both through the fistula and through the rectum. Subsequently the general condition improved, and with aperients the bowels acted both ways. On November 19th it was found that the faecal matter from the fistula had burrowed, and the skin portion of the wound had to be laid open and plugged with iodoform gauze, and subsequently there was slow progress to recovery. When the wound had granulated secondary sutures were put in, which held. The fistula did not close, motions coming both ways.

When the main line of the wound was healed and the skin got into as healthy a condition as possible I operated (February 15th), freeing the fistula, closing it transversely to the long axis of the bowel, returning the bowel into the abdomen and freeing the ileo-caecal junction from the peritoneal and abdominal wound. There was some pain, vomiting, and flatulent distension after this operation. Flatus was passed on February 17th, and on February 23rd the bowels moved freely after a simple enema. The abdominal wound healed well, considering its unavoidable exposure to infection, only two or three sutures working out.

The patient left the hospital on March 15th. He has got much fatter, and I showed him to the Cardiff Medical Society on April 20th, well. The abdominal scars show no signs of weakness, but as a precaution he is wearing a belt.

The points which seem most worthy of attention about the case are—

1. The slight immediate symptoms, the man continuing work for half an hour.

2. The nature of the symptoms. Pain, rigidity, and vomiting were marked, and—if we except the bowel action two hours after the injury—no faeces or flatus were passed. On the other hand, there was little shock and no distension.

3. The blow over the left spermatic cord, with the resulting pain and swelling, being deceptive, as likely to produce some of the symptoms. The cord was cut down on first, for one could not ignore the possibility of strangulated hernia.

4. The intra-abdominal injury was beneath the site of the blow, indicating, in suspected lesions resulting from a localized blow, that it is better to cut down over the seat of the blow than, as was done, in the median line.

5. The fact of recovery, especially when the operation was performed so long a time after the injury. The mortality in 132 cases of ruptured intestine recorded by Berry and Giuseppe is 87.2 per cent.; 84 of these 132 cases were operated on and 17 recovered. These authors do not record one case of recovery amongst those in which operation was performed more than twenty-eight hours after the injury, and only two recoveries when the interval was longer than twelve hours. In the present case the interval between injury and operation was forty-three and a half hours.

6. The possibility of secondary rupture, the entire thickness of the gut wall not being destroyed at first, so that the lumen did not at once communicate with the peritoneal cavity. I believe that the rupture was primary, because the characteristic symptoms of rupture appeared immediately after the injury, the peritonitis was severe and general, and the peritoneum was not less torn than the other coats as if it had given way later. The shape of the hole, a circular opening, much resembling a perforated gastric ulcer, not a linear tear, might be thought to suggest secondary rupture, but other recorded cases in which the rupture was certainly primary, show that the opening may take this form.

7. The rarity of rupture of the sigmoid colon. In 132 cases of ruptured intestine, Berry and Giuseppe only record 4 of rupture in this situation; 3 of these 4 cases were not operated on. In the fourth the rupture was not found at operation. The difficulty of finding it is to be noted in the present case.

8. The establishment of the faecal fistula and the non-drainage of the peritoneal cavity. The faecal fistula was established to relieve the intestinal obstruction caused by the peritonitis. There was no drainage of the peritoneal cavity because of the formation of the fistula, because of the abdomen being got fairly clean, and because drains probably get encapsuled in a few hours.

9. The secondary suture of the granulating wound. When the sutures hold this procedure hastens healing and diminishes the liability to hernia.

10. The closure of the fistulous opening transversely instead of longitudinally to avoid unduly narrowing the bowel.

I can only find notes of two other cases of ruptured intestine that I have operated on.

The first of these was a man aged 28, who after a bicycle accident at Bristol travelled on the following day to Cardiff, and on the next day was admitted into the Workhouse Hospital. Here I saw him at the request of the visiting medical officer, and found evidence of general peritonitis. The patient was exceedingly ill. Immediate opening of the abdomen disclosed a tear 1 in. long of the jejunum and acute general peritonitis. A Paul's tube was sewn into the tear. The patient died shortly afterwards. A post-mortem examination showed no other injuries.

The second case was a man aged 40, under my care in the Cardiff Infirmary, who had received a blow on the abdomen by a piece of iron, which crushed him against a wall. I did not see him till fourteen hours after the accident, and operated immediately. On opening the abdomen, I found a piece of small intestine, 4 in. long, with its mesentery actually loose in the abdominal cavity, so that it could be picked out. There was much blood in the abdomen. The peritoneum in several places was torn. The intestine was joined by end-to-end union, other parts repaired, and the abdomen cleaned out. The

patient was extremely ill before operation, and died seven hours later. Although there were no signs of external bruising in this case, it was noted, when opening the abdomen, that the left rectus was torn completely across. On admission the patient had a pulse of only 84.

Traumatic rupture of the intestine is, as might be expected, more common in males than in females. Such injuries are produced either by squeezing, such as occurs in "run-over," or by a blow, the blow being sharp and unexpected, so that the abdominal muscles have no time to contract and protect the underlying parts. The rupture is due to crushing of the intestine between the force applied and some portion of the bony part of the posterior wall of the abdomen. More fixed parts of the intestine are more liable to injury than more movable parts, and therefore the duodenum and the lowest part of the ileum being more fixed, are somewhat more liable to injury. Injuries to the small intestine are shown by Berry and Giuseppe's tables to be more common than the large. Multiple ruptures are not uncommon. Partial (all the coats not being involved) and retroperitoneal ruptures occur rarely. The injury, of course, may be complicated with other injuries.

The three important symptoms are pain, vomiting, and rigidity. These are hardly ever absent. Other important symptoms are tenderness, sometimes localized, and cessation of the action of the bowels. Shock, which one would naturally expect, is a very inconstant symptom, and the pulse-rate is often not increased at first. Berry and Giuseppe say, "In many of our cases shock was entirely absent. Several of the patients walked home after the accident. Some of them walked to the hospital. Two of the patients went on with their work. Case cxxiv remained at work for four hours, and Case cxxxi wheeled his barrow home before going to the hospital."

Rigidity is hard and board-like in character. It is due to the abdominal muscles, so to speak, splinting the injured parts beneath them. A rapid pulse should never be waited for, neither should distension, for it is a late symptom, and so serious as almost to obviate the possibility of recovery under any circumstances.

Vomiting, frequent and in small quantities, is almost always present. Dullness is not very helpful. It is a symptom which more often occurs when blood is extravasated, as through injury to a solid organ. Absence of the liver dullness, a physical sign which is always looked for and its presence or absence carefully noted, is characterized by Berry and Giuseppe as a sign "of the worthlessness of which in the diagnosis of ruptured intestine we cannot speak too strongly." Of Berry and Giuseppe's 132 cases, 48 were not operated on, and they all died. Of the number operated on—namely, 84—17 recovered and 67 died, an operation mortality of 80 per cent.

With regard to treatment, early operation is the key to success. Little harm is done by opening the abdomen needlessly, while waiting for more pronounced symptoms is the cause of many a death. Where great pain and great rigidity are present we should not wait for a rapid pulse or for a distended abdomen, for the time for successful operating will then probably have passed by. With regard to operative details, knowledge of the site of the blow (if a blow has produced the injury), localized dullness or localized tenderness may all help to indicate where to cut down. The rupture is not always found. It was not found in 15 out of the 84 cases recorded by Berry and Giuseppe. When found it is best closed by simple suture. The questions of irrigation *versus* mopping and drainage or no drainage of the peritoneal cavity will probably always be determined differently by different operators. Enterostomy is of value when the symptoms of ileus are marked. An appendicostomy may be substituted.

In conclusion, I would emphasize the fact that early operation is the key to success in these cases; that pain, rigidity, and vomiting are the three symptoms which alone we must constantly expect, and that sitting up in bed, slow rectal saline infusion, and sometimes an enterostomy, are important points in the after-treatment.

THE King of the Belgians has given his estate of Saasable on the Gulf of Villefranche for the purpose of a convalescent home for sick and convalescents from the Congo Colony. The property is said to be one of the most beautiful on the Riviera.

* Recently I successfully closed the abdomen without drainage after operating for a perforated gastric ulcer.

THE TREATMENT OF SEVERE CASES OF CHRONIC COLITIS.*

By P. LOCKHART MUMMERY, B.C., F.R.C.S.,

SENIOR ASSISTANT SURGEON, ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM AND TO THE QUEEN'S HOSPITAL, HACKNEY.

Cases of chronic colitis naturally divide themselves into two distinct classes:

1. Those cases which if carefully treated by suitable dietary, proper regulation of the bowels, and perhaps one or more visits to some suitable spa where proper lavage of the bowel can be carried out, quickly get well, and remain well; and

2. Cases in which in spite of prolonged and careful medical and spa treatment, little if any improvement occurs, or the improvement is only temporary, the patient quickly relapsing and the symptoms in spite of continued treatment getting worse.

I think every one who has had any experience in the treatment of chronic colitis will admit that this second type of case not only exists but forms an unpleasantly large proportion of the whole.

The worst cases in this second class spend their time going from one doctor to another, and in visiting most of the English and Continental spas. Many of them go in for Christian Science, vegetarianism, or other forms of quackery. In fact, they form one of the worst classes of chronic invalids, a nuisance to their doctors, their relatives, and themselves. It naturally occurs to one to ask what is the reason that the treatment which seems so effectual in the first type fails so signally in the second. The reason is, I think, not far to seek—chronic colitis is a condition usually diagnosed from the symptoms alone, and I think we shall all admit that the treatment of a disease which is only manifest by its symptoms is always difficult, and owing to the large possibilities of error which must be present in any diagnosis founded only upon symptoms, often unsatisfactory.

During the last few years I have seen a considerable number of the more severe cases of chronic colitis, both in hospital and in private. Most of these cases had previously been treated medically for long periods, and many had also been to spas and had Plombières treatment. For the most part they belonged to the second class of cases that I have mentioned, and medical treatment had failed to give them any permanent relief. All the cases that I have seen have been examined with the sigmoidoscope, and in many an operation has been performed which has enabled me to examine directly the colon and so to ascertain the exact nature of the pathological lesion.

I have no hesitation in saying that all cases presenting symptoms of chronic colitis should be most carefully examined with a view of ascertaining the exact nature of the lesion in the colon. The chief reason for the unsatisfactory results that are often seen in cases of chronic colitis is that the symptoms ascribed to this disease may result from a great many different conditions of widely different characters, and the treatment which is suitable for one case is not suited to others. Our aim in all such cases should be to find out if possible the real cause of the symptoms. This is admittedly not always possible, but, on the other hand, it often is.

In a paper read before the Royal Medical and Chirurgical Society in June, 1907, I first pointed out that in the great majority of cases of chronic colitis a lesion or lesions could by suitable means be demonstrated in the colon, that these lesions varied considerably in different cases, and that any treatment which did not take into account the cause of the symptoms is unsound in principle.

The name "chronic colitis" should be reserved for those cases in which there is a chronic inflammatory condition of the mucous membrane of the colon. They can be distinguished readily by examination with the sigmoidoscope, as the sigmoid flexure is practically always involved.

The cases in which there is a definite inflammatory condition of the mucosa, as seen on sigmoidoscopic examination, are those which are suitable for treatment by lavage and the Plombières douche. Many of them in my experience do well. They form the first class of which I have spoken, and the majority of all cases. On

the other hand, there are many cases with identical symptoms in which, on examination with the sigmoidoscope, we find the mucous membrane quite normal, but some other lesion is present. It is this class of case which I propose to consider in detail. In many there is no inflammation of the mucosa of the bowel, while in others in which there is, it is purely secondary to some other lesion. The nature of the lesion varies considerably. An important class is that in which some chronic obstructive lesion exists in the colon, such as adhesions from previous peritonitis or perimetritis. Or a kink or acute angle is present in the pelvic colon as the result of adhesions to the iliac fossa or in the meso-sigmoid, probably due to old chronic constipation. Another form of lesion is that in which there is a partial volvulus of the sigmoid, or a chronic and recurring intussusception.

We must also bear in mind that cancer of the colon may cause symptoms of chronic colitis, which are indistinguishable from those occurring in the simpler forms. I have seen seven such cases, in several of which the patient had previously undergone treatment for months for a supposed simple chronic colitis.

In another well-marked group of cases we find a chronically inflamed appendix, which, owing to the fact that it has not caused the usual distinctive symptoms, has remained undetected. There is no doubt that a chronically inflamed appendix may cause symptoms of chronic colitis, though exactly how it does so is not always clear. In some instances it is due to adhesions which have formed to the pelvic colon, while in others it probably produces symptoms by the constant discharge of septic material into the bowel, in the same way that carious and septic teeth will cause gastric disease.

There is one well-marked group of cases in which all the symptoms of a severe chronic mucous colitis exist, and in which there is no inflammation of the mucosa, but the whole colon is found to be lax and atonic. On examination with the sigmoidoscope the bowel is seen to be unduly lax and to have a marked tendency for the upper portions to prolapse into the lower; the walls are thin and semi-transparent; the lumen is dilated, and the normal sacculata much exaggerated. There is generally well-marked ptosis of the transverse colon and of the stomach. In several instances in which I have operated for this condition the centre of the transverse colon has been found in the bottom of the pelvis lying in front of the other part of the rectum. In this type of case the colon is dilated and its walls atonic, but there is no inflammation of the mucosa. It is obvious that it is most important to be able to distinguish this type of case, as treatment by lavage which involves distension of the already dilated colon will not only be useless but will do harm. Such cases are not suitable for Plombières treatment. It is quite obvious that these different conditions, although they cause the same symptoms, cannot be classed as one disease.

I cannot believe that the neurotic element which is so commonly present, and about which we hear so much, is other than secondary. I have frequently seen it entirely disappear after the cause of the symptoms has been removed.

One of the chief reasons for the unsatisfactory results that have been obtained in the treatment of many cases of colitis has been inaccurate diagnosis, and treating as a disease what is only a symptom.

The indications for operating in cases of chronic colitis will, of course, depend upon the nature of the lesion present. When there is any evidence of an obstructive lesion such as adhesions or chronic volvulus, laparotomy is clearly indicated, and affords the only possible method of adequately dealing with the case.

The following is a good instance of the type of case which can only be treated satisfactorily by operation.

The patient, a married lady, was recently sent to me by her doctor. For ten years she had been a chronic invalid with mucous colitis. She suffered from chronic pain in the abdomen, which at times became severe, and was always worst on the left side. She had lost weight, and always felt ill and depressed. She had fits of weeping, and misery on the slightest, and often upon no, provocation, and was unable to go about or enjoy life in the ordinary way. She had an earthy complexion, and her appearance when I saw her was typical of toxæmia or auto-intoxication. The stools contained large quantities of mucus, and often consisted of little else. A curious and unusual symptom was that the presence of anything in the rectum caused

* A paper read before the Balmological Society.

an uncontrollable desire to go to stool and much tenesmus. She had been under medical treatment for years, and all the recognized forms had been tried. On examining the bowel with the sigmoidoscope I found the mucosa quite normal in appearance. In the middle of the sigmoid, however, the bowel was found to be firmly fixed and angulated, apparently by adhesions. The uterus was also found to be markedly retroflexed. It seemed probable that the tenesmus from which she suffered was due to the condition of the uterus, and a gynaecologist who saw her with me confirmed this view.

I opened the abdomen and found a number of firm adhesions binding down and kinking the middle of the sigmoid flexure; these were divided and the wound left in the peritoneum seven up. The uterus was also drawn forward and anchored to the abdominal wall so as to correct the position.

The patient made a good recovery, and all her symptoms have now completely disappeared. When I last saw her some months after the operation she had put on weight, her complexion was good, she no longer had any mucus in the stools, and she told me that she never remembered feeling so well and fit.

Though most of the cases of true colitis (that is to say, when a chronic inflammation of the mucosa of the colon is found) get well as the result of medical treatment and lavage, there are nevertheless a certain number which either fail to get entirely well or suffer from frequent relapses. These cases are, I believe, best treated by appendicostomy, which enables the patient to keep the colon efficiently washed out daily with the minimum of inconvenience, and the symptoms quickly clear up.

The most difficult cases to treat are perhaps those in which there is a general atony of the bowel combined with ptosis of the colon. Stitching up the colon is quite useless, as it is unreasonable to expect any stitches to hold up the stomach and transverse colon permanently when the natural supports have not been sufficient to do so. It is impossible to deal directly with the condition, but I have had very satisfactory results in such cases from appendicostomy, and the fitting of a belt to support the abdomen. The object of the operation in such cases is to prevent the stagnation of the faecal contents of the colon, which is the chief cause of trouble, and at the same time by the introduction of suitable peristaltic stimulants to improve and restore the muscular tone of the bowel wall.

The following well illustrates this type of case:

Mrs. B., aged 32, a married lady, was sent to me by her doctor suffering from severe chronic colitis. There was a history dating back twelve years, though the symptoms had only been really severe for the last four years. She always felt ill, and had a chronic aching pain in the left side of the abdomen. She was always very constipated, and had to take large doses of aperients, and this often without success. The stools contained mucus, and often large casts over a foot in length. She had been treated for long periods by the usual remedies, and had on different occasions consulted several well-known physicians, but without obtaining any relief from her symptoms.

Examination showed an atonic condition of the bowel, and chronic inflammatory changes of the mucosa. There was also well-marked ptosis of the transverse colon.

I operated, and on opening the abdomen found the colon much dilated and thin. There was also considerable enteroptosis. Appendicostomy was performed, as the only alternative seemed to be removal of the colon.

The colon was subsequently irrigated daily with warm water (at first in small quantities) to which a teaspoonful of ox bile was added. She rapidly improved in health, and learnt to wash out the bowel for herself. The mucus entirely disappeared from the stools, her health improved, and the bowels acted without any aperient being used. During the next six months she put on 2 st. in weight, and when I last heard from her, about nine months after the operation, she was quite well, and although on my advice still washing out the bowel, was quite free from any of her old symptoms.

Appendicostomy is an operation followed by excellent results in many of these cases, but it is not a panacea for all cases of so-called chronic colitis any more than is lavage. It should only be performed in suitable cases, and that can only be done if we first ascertain the cause of the symptoms. I have seen cases in which appendicostomy has failed even to relieve the symptoms because there was some obstruction or other lesion which had not been detected.

I do not wish it to be thought that I am advocating operation in all cases in which there are symptoms of chronic colitis. I think operation should only be resorted to after a careful trial has been given to medical treatment. But the important thing is to ascertain the cause of the symptoms by a careful examination aided whenever possible by the use of the sigmoidoscope, as it is useless treating a case by medical measures where there is an obstructive lesion in the colon, or a chronically inflamed

and thickened appendix. And, in any case, it is not satisfactory to institute treatment without knowing the cause of the symptoms.

ENTEROSPASM: OPERATION: DEATH.

By VAUGHAN PENDRED, M.D., DUB., F.R.C.S., ENG.

COVENTRY.

MR. C. W. DRAN'S case of enterospasm reported in the *JOURNAL* of March 13th recalls a similar case I had under my care four years ago, which ended fatally, and on which I obtained a partial autopsy:

The patient was a querulous, excitable, grey-haired little woman aged 57 when I first saw her in October, 1904. She was fat and healthy-looking. For the preceding three years she had suffered from time to time from colic with vomiting and diarrhoea. Latterly these attacks had become very frequent and severe. The tongue was coated. The urine showed a trace of albumen, and she complained of frequent micturition. During the next two months, in spite of energetic treatment, she had much colic and some hæmaturia, and had plainly emaciated. A copious bleeding from the rectum occurred about this time.

In January, 1905, I sent her to Guy's Hospital, where some improvement took place during her month's residence. An x-ray photograph of the abdomen was negative. Movable right kidney was diagnosed and the wearing of a belt advised.

Month after month she continued to waste, and had constant vomiting attacks. Constipation alternated with diarrhoea, which latter somewhat relieved her pain.

In July, 1905—or ten months after my first notes—she was nearly bedridden with colic, coming on every few minutes, accompanied by tremendous borborygmi. Visible peristaltic waves passed across coils of intestine from left to right every few minutes, as though the intestine were endeavouring to overcome some obstruction. By the end of this month her condition was pitiable, and I had to keep her constantly under the influence of morphia. The pain was almost constant night and day. The vomit now became serous, and she could not supervene, and the bowels were confined. In short, the symptoms pointed to intestinal obstruction.

On July 29th I opened the abdomen below the umbilicus, but at first could find nothing amiss. Some feet of small intestine, distended but healthy looking, prolapsed through the wound. At one point the distension of the gut suddenly ceased, and the distal portion was flat, toneless, and of a paler colour, so that I thought that I had discovered the obstruction that I sought. Whilst I was considering what I would do next, the collapsed gut began to fill out again just as it had appeared to do through the abdominal wall. In order to return the gut it was necessary to incise a prominent coil, from which gas and foul liquid faeces escaped.

Three days later her condition was as bad as ever. The gurgling, peristalsis, pain and sickness, with occasional hæmaturia, being nearly continuous. She died in the middle of September, emaciated to a skeleton, as she was unable to take food for many days. The peristaltic waves were a marked symptom up to the last moment of her life.

A post-mortem examination of the abdomen was all I could obtain leave to make. Every organ, though wasted, was macroscopically healthy. The intestine was partly opened up, and presented a normal appearance. Portions of the organs were sent to a London pathologist, who confirmed my opinion of them.

This case parallels Mr. Dean's in many particulars. Both patients had suffered from abdominal pains, vomiting, and bowel trouble for some years. The appearance of the ileum at the operation was similar. In Dr. Ashe's and my case the flattened gut "lived up" under observation. Anorexia and utterly uncontrollable vomiting, with occasional hæmaturia and melaena, were such prominent symptoms in my case, that they point to a profound toxæmia, and not merely to a disturbance of innervation of the intestine.

FISTULAE BETWEEN THE STOMACH AND BILE PASSAGES, ETC.

By ALEXANDER DON, C.M., F.R.C.S., M.A.,

SURGEON, ROYAL INFIRMARY, DUNDEE.

THE CASES of unusual fistulae in the *JOURNAL* of May 1st by Mr. Mayo Robson make one think that the unrecorded cases may be more numerous than would be expected, and the following three may be of some interest:

M. L., aged 32, a multipara, whom I saw with Dr. Lawson on June 17th, 1899, had the following history: From November, 1898, she had repeated attacks of biliary colic, which developed in intensity till April 5th, 1899. The vomit was at times

Gilious and the pain was intense, an attack usually lasting for more than a week. The most severe attack was in April, and at that time she was confined to bed for a fortnight, and was extremely ill; but, owing to her condition—she was then in the seventh month of her pregnancy—operation was declined. The abdomen was noted to be unusually large. On the morning of June 13th she had what seemed to be the beginning of another attack, and an opiate was given to relieve the pain. This subsided, but next morning her doctor was summoned early and found labour apparently progressing normally, though the patient was in rather a collapsed condition. After the birth of the child haemorrhage continued very freely, and I was sent for. On my arrival the patient was moribund. On examination by the vagina I discovered a second child lying high up in the uterus, which was quite lax. The child was turned and delivered without any difficulty, but the uterus did not contract, and was found to be firmly fixed to the liver. No manipulation could free it. There was no question of its rupture, as the wall could be felt distinctly, and the hand passed up till the liver was reached. The patient died from loss of blood shortly after the delivery of the second child. No post-mortem examination was allowed.

The probable course of events in this case was gall-stone colic with inflammation, and in April a fistula had been formed into the colon or duodenum, and relief had been obtained at that time; but so much inflammatory adhesion had occurred that the uterus must have then become fixed to the colon or liver. At any rate, after this attack she was comparatively free from pain till her confinement in June, when the uterine contractions again caused a semblance of biliary colic.

The second case was a farm servant, J. C., aged 43, who consulted me in April, 1902, about an attack of indigestion with extreme pain. The pain always followed ingestion of food, reaching its greatest intensity about three hours after eating, and being relieved by complete emptying of the stomach by vomiting. I advised operation, but he would not at the time consent, and he was treated by dieting and bismuth carbonate, under which he improved considerably and was able to resume work. In June of the same year the pain recurred, and there was severe haematemesis on the 12th of that month, which so alarmed him that he consented to operation. At the operation the stomach, from the middle of the lesser curvature to the pylorus, was found to be firmly adherent to the under surface of the liver. When these adhesions were freed a large opening was found in the anterior surface of the stomach near the pylorus, and a large eaten-out cavity in the liver from which bleeding was persistent. This cavity measured 2 in. by 1 in., and about 1 in. deep. The cavity was packed with iodoform gauze. The opening in the stomach was closed, and a drain left in the upper angle of the abdominal wound. The patient died next day. The condition was one of gastric ulcer perforating after adhesion to the liver.

The third case was seen in consultation with Dr. Macdonald of Dunkeld in November, 1903. Miss J., aged 43, had suffered from indigestion when in Ireland twelve years previously. In October she began to vomit a dark-coloured fluid. All day the mouth was stopped, but the vomiting still persisted, amounting to several pints daily. No drug had any effect, and she got very weak and emaciated. Malignant obstruction about the pylorus was diagnosed, but very little beyond a marked resistance to palpation could be made out. The puzzling thing was the amount of fluid which must be returning through an obstructed pylorus, and which seemed to be pure bile. An alternative diagnosis was gall-stone obstruction by ulceration and blocking of the duodenum, and it was only at the operation that the diagnosis was cleared up. The gall bladder was found adherent to the front of the stomach 1½ in. above the pylorus, and the pylorus felt hard and fixed. The patient's condition was so poor that a posterior gastro-jejunostomy was performed. She rapidly recovered, and was enjoying light diet and sitting up in a fortnight. She then had another attack of vomiting, with marked nervousness and sleeplessness. This came on always at night; and, as nothing was found in her condition to account for it, she was allowed at her own request to go home, where she again rapidly recovered, and is now quite well, and able to attend to her household duties.

In this case the ulcer may have been gastric, and have penetrated after adhesions into the gall bladder, or it may have been biliary from gall stones, and ulcerated into the stomach. In either case the condition set up pyloric inflammation and thickening with obstruction, which was relieved by the gastro-jejunostomy. It is quite likely that the inflammatory condition at the pylorus may have subsided later and the pylorus again become patent; but, in any case, the proper treatment at the time seemed to me to be a gastro-jejunostomy. There was not much matting about the bile passages. The gall bladder adhered only at one point where the fistula existed, and nothing was discovered elsewhere to lead one to think that this case was originally one of gall stones rather than of gastric ulcer.

A FATAL CASE OF ACUTE VOLVULUS OF THE ILEUM.

By S. E. DENYER, C.M.G., M.D., M.A.CANTAB.,
F.R.C.S. ENG.,
HULL.

I AM indebted to Dr. W. A. Bryant for giving me the opportunity of seeing and recording this case, which is of interest from a diagnostic as well as a forensic point of view.

History.

The patient, a man aged 23, a fitter, went to bed on the night of April 29th apparently in good health. He had done an ordinary day's work, and had not complained of any ill-health. At 3 a.m., while in bed, he was suddenly seized with acute abdominal pain and vomiting. This continued until 8 a.m., when Dr. Bryant was sent for. He saw the patient at 8.7 a.m., and found him in a state of collapse, pulseless, and with no audible heart sounds; respirations were five or six a minute, and spasmodic in character; the pupils were dilated. He gave a hypodermic injection of strychnine and digitalin, after which the pupils contracted, but there was no other reaction. The patient died at 8.15 a.m.

Dr. Bryant was told that the patient had had attacks of pain in the chest and back for some time, and his wife had recommended him to go to a doctor, but he had refused. Otherwise he had been healthy.

Necropsy.

The body was that of a well-nourished man, looking about the stated age. There was no sign of any external injury. Rigor mortis was well marked. The muscles were found to be healthy, normal in colour, and well developed.

Heart.—Muscle and valves healthy, no sign of disease in the coronary arteries. A small quantity of clear fluid in the pericardial sac.

Lungs.—Some oedema at bases, and on the left side some old pleurisy, otherwise healthy.

Thoracic aorta healthy; no atheroma.

The brain and meninges, as well as the arteries of the brain, were healthy.

Abdomen distended; on opening the abdominal cavity a large coil of intestine was found presenting. This coil was placed vertically, and was about 20 in. in length. It was very much distended, being about the diameter of an ordinary man's coat-sleeve, and was of a deep purple colour, almost black. At first, on account of its size and position, it was thought to be the transverse colon much dilated, but closer investigation showed that it was the ileum in an abnormal position. There was no peritonitis, nor any sign of perforation or gangrene. The stomach was collapsed and empty, excepting for an ounce or two of fluid contents, consisting of watery mucus with no unusual smell or appearance. The oesophagus and duodenum as well as the stomach had no sign of inflammation, corrosion, ulceration, or perforation; the mucous membrane was pale, but otherwise normal. There were no adhesions in the neighbourhood of these organs.

As the jejunum passed into the ileum it was found to become congested and distended, becoming more so as it lower part. The ileum was distended throughout its whole extent, but mostly in its lower two feet, which presented the appearance described above. The peritoneum of the posterior abdominal wall on the right side, as it left the root of the mesentery, had a dragged appearance, and the mesentery in the neighbourhood of the caecum was twisted on itself. On opening the ileum it was found to contain a large quantity of dark, opaque, and its walls were black with congested blood. On peculiarity noted was that this area of intense congestion suddenly ceased at the ileo-caecal valve; the mucous membrane of the caecum was very pale but otherwise quite normal in appearance. On the other hand, the congested condition of the ileum gradually lessened above. There was no foreign body in the intestine. The large intestine was very contracted and pale, and seemed smaller than normal, and this contracted appearance was common to the whole of the large bowel. The appendix was healthy.

It was situated in the right iliac fossa, where the caecum was also found in its usual position. There was no evidence of any congenital maldevelopment. Meckel's diverticulum was not found. There was no sign of internal hernia in any part of the abdomen. The superior mesenteric vessels were normal in appearance, and there was no sign of portal thrombosis or embolism. The pancreas was healthy, and there was no sign of fatty necrosis. The kidneys and suprarenal bodies were healthy. The bladder was contracted and the urine contained no sugar. The liver and gall bladder and its ducts were healthy, and there were no adhesions around these parts. The abdominal aorta and inferior vena cava presented no sign of disease. The spleen was rather large but otherwise was normal. There was no fluid in the abdominal cavity.

From the history of the case and the post-mortem appearances, it is evident that it was one of acute volvulus of the ileum. The constriction was definite below at the ileo-caecal valve; above it was difficult to say where the gut was gripped, as no sign of constriction could be found

In doing a *post-mortem* examination of this kind, one naturally looks first for the commoner causes of acute disease, and the appendix is early searched for on this account. Unfortunately, the moving of the intestines in the search for the appendix disturbed the position of the ileum, and the position of the upper limit of the volvulus must remain more or less hypothetical. The extreme distension affected about 20 in. of the ileum, and the upper limit of the volvulus was probably in this position. In recorded cases of volvulus of the ileum, both the upper and lower limits seem in some cases to have been more or less indefinite.

Death supervened in five hours in this case, and was undoubtedly due to shock following an acute strangulation of a comparatively large amount of bowel, and that bowel part of the small intestine which is of much more vital importance than the large. From the immense size this part of intestine reached, and the amount of congested blood in it, there was practically a severe haemorrhage into it, as far as the general circulation was concerned. This must have greatly increased the already severe shock from which the patient was suffering.

Shock is defined as a condition of exhaustion of the vasomotor centre. Crile has shown that if the abdomen of an animal is opened and the intestines exposed, a fall of blood pressure occurs. This is associated with a vascular dilatation of the splanchnic area, and a marked degree of shock occurs. The animal bleeds into its own portal system. Anaemia of the vasomotor centre results, and sets up a general vasomotor paralysis, which increases as the vasomotor centre becomes exhausted. Treves states that "the grave initial symptoms of intestinal obstruction do not depend upon the fact that the bowel is obstructed, but upon the severe injury to the sympathetic nerves involved." Crile's observations show that this injury acts by producing an inhibition of the vaso-constrictor nerves, and ultimate paralysis of these nerves by exhaustion of the vasomotor centre. The resulting dilatation of the vessels of the splanchnic area causes a great fall in the systemic blood pressure and coincident shock.

In the case of this man there was an added haemorrhage into the part of the intestine forming the volvulus, thus increasing the factors causing shock, and making it much more profound owing to the added anaemia of the brain.

I can find no record of death ensuing in so short a time from intestinal obstruction, although several cases have been recorded where death ensued within twenty-four hours. Dr. Bryant suggests that the man was one who did not complain much, and that he may have had some pain earlier than the time stated.

The part of the ileum involved in this case, the lower part, is most frequently the seat of volvulus when it occurs in the small intestine. Treves says "the majority of patients exhibiting this form of volvulus have been males with a mean age of 25 years." Cases of volvulus of the small intestine in cases of typhoid fever, simulating perforation, are mentioned by Roberts; the symptoms were severe abdominal pain and collapse. Eliot has recorded a case in which a volvulus of the ileum, associated with one of the pelvic colon, caused great shock, with a pulse of 140, thready and very weak, coldness and lividity, and apathy, but the facial expression showed intense suffering. In the case I have recorded the symptoms of shock were present to such a degree as to cause death within a few hours.

TWO CASES OF APPENDICITIS.

By H. GOODWIN, F.R.C.S. Edin.,

DOVEY TRACEY.

The following two cases of appendicitis presenting some unusual features are, I think, worth recording.

CASE I.

Mrs. C., aged 36, had for a period of two months repeated attacks of severe appendicular colic, accompanied on each occasion by a rise of temperature—101° to 102°—with severe abdominal pain, referred at first to the umbilical region, and latterly localized to the region of the appendix, the maximum point of tenderness being over McBurney's point. These attacks subsided under hot fomentations, rest in bed, etc., but the attacks became more frequent and intervals shorter; also they were more severe in character. The patient was three months

pregnant, but in the light of the increasing severity of the pain, and frequency of attacks, it was decided to operate, and at the worst the risk of miscarriage was less than the possibility of the formation of an abscess.

Operation.—The caecum was much bound down by adhesions, and the tip of the appendix was adherent to the pelvic brim. There was great difficulty in withdrawing the caecum sufficiently to expose the base of the appendix, and to free the appendix itself, owing to numerous adhesions, but eventually this was accomplished, and a long inflamed appendix was removed, and the stump invaginated by purse-string suture, and covered by Lembert's sutures.

The subsequent history was uneventful; on the next day temperature and pulse were normal, and on the fourteenth day the patient returned home; no signs of uterine disturbance had occurred, and she remained well after six weeks. On opening the appendix, a nematode worm about 1½ in. in length was found, and there was a haemorrhagic condition of the mucous lining of the whole organ, and an ulcer commencing to form on the floor, which would in all probability have gone on very shortly to perforation. I think the result amply justified the possible risk of cutting short the pregnancy.

CASE II.

A child aged 4, who for about twelve months had had attacks, none very severe, of abdominal pain without localized tenderness, principally referred to the umbilical region. Six weeks before operation she had a severe attack of pain, with rise of temperature to 102°; vomiting and marked constipation. There was no tenderness over the appendix at first; in about four days the pain was localized. The appendix, which was much inflamed, 4½ in. long, and considerably swollen, was isolated without difficulty. It was treated by invagination with purse-string suture, and closed over with Lembert's sutures. The recovery was uneventful; there was no rise of temperature or pulse, and the stitches were removed on the eighth day.

On opening the appendix a haemorrhagic condition of the mucous lining was seen, and a small fishbone, about ½ in. long, lying free in the lumen. There was also evidence of an old kink, as represented by a transverse band of scar tissue.

Both these cases are illustrative of the advantage of early operation when symptoms of colic recur without obvious cause; in the second case, though the temperature and pulse became normal in a few days, during the whole five weeks there was never complete freedom from slight attacks of pain, sometimes lasting only a few minutes, not from tenderness on deep pressure over the appendix.

The technique I practised was by incision through the skin over the outer border of the rectus, which was pushed inwards without splitting its fibres. I think this method has distinct advantages over the gridiron method, as especially in the first case it would have been nearly impossible to obtain sufficient room for the necessary manipulations without dividing the fibres of the internal oblique and transversalis. I followed Professor von Eiselsberg, of Vienna, in painting the skin with a spirit lotion of iodine liniment both before the incision and after the stitches were introduced.

A CASE OF VERY LARGE GALL BLADDER SUCCESSFULLY TREATED BY EXCISION.*

By F. W. COLLINSON, M.D. Edin., M.R.C.P. Lond., F.R.C.S. Edin.,

HONORARY MEDICAL OFFICER, PRESTON ROYAL INFIRMARY.

This case is remarkable owing to the immense size of the gall bladder, being amongst the largest on record.

Mrs. S., aged 31, was sent to me by Dr. Callanan of Longridge on October 14th, 1908, suffering from general abdominal distension and pain in the right side of the abdomen.

History.

There was nothing of note in the family history, as all were healthy; the mother had died in childbirth. The patient herself had always been in good health, though pale. She had two children, now living and healthy, born six and three years ago, with one miscarriage in between them.

The history of the present affection appeared to date from August, 1907, when she had a fall, for soon after she began to vomit each day, and in December she remained in bed on that account. She distinctly said there was then no swelling of the abdomen. In January she observed a swelling of the lower part of the abdomen towards the right side. On February 13th she had greatly increased in size, and was somewhat emaciated and markedly jaundiced. She was tapped, and 25 pints of fluid was drawn off, and the fluid must have been similar to that removed afterwards at the operation. Dr. Callanan was able to "feel the liver for 2 in. or 3 in. below the ribs," but he was not able to reach, rather prophetically, "this may, of course, be the sac of

* Notes read, and patient shown, to the Clinical Branch of the Preston Medical-Ethical Society, February 3rd, 1909.

a cyst." It might have been the cyst contracted, but it was more likely to be the liver, as the cyst would tend to fall away from the liver in all probability, for there would not be any adhesions at the first tapping, as they would arise from cozing after the puncture. Her general health improved, and the jaundice diminished. She, however, began to refill, and on April 10th 25 pints were again drawn off. Her general health still further improved, and her menstruation, which had ceased in the December, recommenced in June, and was regular up to the operation.

Condition when First Seen.

Upon examination there was no cachexia or jaundice and her pulse and temperature were normal. Excepting the evident enlargement of the abdomen there did not appear to be much the matter with her. The circumference at the umbilicus was 40 in., although she is short in stature. The abdomen did not appear irregular to touch or appearance; it was quite uniformly dull all over, as I failed to find a tympanic area anywhere. It did not feel tight, but soft and fluctuating and a thrill was readily propagated in any part. On vaginal examination the uterus was found to be normally placed, and there was not any bulging in the fornices. The diagnosis was not by any means clear, but, as Kocher says, "the conspicuous bulk of the growth at once turns the thoughts of the observer to the commonest form of abdominal tumour, ovarian cyst." I thought it most likely to be an ovarian cyst, but could not be certain, and, as a matter of fact, in my notes I placed a question mark against the diagnosis.

The same day she was admitted into Preston Infirmary. The urine was 1028, acid, no albumen, no sugar, urates, and no marked coloration of bile, though it must be confessed we did not think of testing for bile, as we did not get the history of jaundice till afterwards from Dr. Callanan.

Operation.

On October 19th Dr. R. M. Glover gave chloroform, but quickly changed to ether by the open method, which he continued throughout, and with the assistance of Dr. A. Toulmin I operated, the incision being in the middle line below the umbilicus. It was impossible to make out the layers of peritoneum and sac owing to the very firm adhesions, and the uncertainty was so great that we decided to empty the sac with a large trocar, and 20 pints of thick gamboge-coloured liquid escaped, leaving 2 pints at least in the bottom of the cyst. Upon opening up the sac, the velvety appearance of the inner lining was remarkable, reminding us of miniature valvulae conniventes covering the whole surface.

Commencing to separate the cyst, we found that it meant really tearing the sac from its attachments to the entire anterior abdominal wall, the bladder, the spleen, the stomach, and the liver. Fortunately it was not anywhere attached to the intestines, or the firmness of the adhesions would have rendered removal quite impossible; the intestines were all placed quite behind the cyst, which formed a complete cover to them. More fluid continued to well up into the cyst, and was seen to be coming out of the dilated cystic duct. There were not any calculi to be found. Another sinus ran up towards the right kidney, but it proved to be a cul-de-sac formed possibly by the pushing of the cyst upwards into that region. When the cyst was separated up to the under surface of the liver, the patient became so exceedingly collapsed, from the length of the operation (about two hours) and the violence required in the separation of the adhesions, that the anaesthetist asked for the operation to be brought to a speedy conclusion; hence careful examination of the common duct and hepatic duct was impossible, and we had to be content with cutting off the sac and ligaturing drainage tubes into the cystic duct and the aforementioned cul-de-sac, and rapidly stitching up the abdomen.

The collapse was great, but with the aid of hypodermic and rectal saline injections the patient gradually improved, and in forty-eight hours the pulse was 80 and of good tension. The quantity of urine during the first week was 14 oz., 18 oz., 20 oz., 16 oz., and 12 oz. The temperature immediately rose to 102, and remained so till the tube was replaced, when it became normal. The tube was removed altogether on December 20th, when the amount of fluid in twenty-four hours was from 2 oz. to 4 oz., and it had changed to a yellowish purulent fluid. There was never any bile in her urine after the operation; the faces were very pale at first, but gradually deepened to a colour. She left the infirmary on January 3rd, the sinus being dressed once in twenty-four hours, and discharging about 1 oz. The skin throughout the whole illness was never irritated by the bile. When last seen, on March 20th, she complained of occasional gain in the region of the liver, and her mouth temperature was 99.2°. She described her health as good, and said she was quite able to do her housework. The faces have been for some time colourless. She is pale, but as stated before, has always been so. There was only slight moistening of the small pad covering the sinus.

Specimens of the fluid and of the cyst wall were sent immediately after the operation to my friend, F. W. Enrich, M.D. Edin., Honorary Physician and Honorary

Pathologist to Bradford Infirmary, and he kindly reported as follows:

The cyst wall is composed of dense fibrous tissue, the fibres arranged parallel to each other. Its outer half is poor in cell elements. Its inner half is cellular, showing hyperplasia and multiplication of the fixed tissue cells, and also small round-cell (leucocyte) infiltration. These cell masses are developed at fairly regular intervals, so that the inner surface of the cyst wall is thrown into folds. The inner surface is covered by a thin layer of necrotic tissue in which no structure is recognizable. No epithelial elements are visible. A grain of bile pigment adheres in places to the inner surface. The contents of the cyst separate, on standing, into three layers. The upper consists of bile-stained fat, the middle of a dense albuminous liquid, bile-stained; the lowest of a granular deposit of bile pigment. Chemically the fluid is rich in albumen, fat, bile pigment, and bile acids. There is no cholesterin. Faintly alkaline. Microscopically fat globules and bile pigment, a few isolated leucocytes, and one or two large (epithelial) cells distended with fat globules. Specific gravity 1017. Diagnosis, distended gall bladder, chronic inflammatory induration.

In 1905 Alban Doran delivered an interesting clinical lecture at the Samaritan Free Hospital for Women upon Dilatation of the Gall Bladder Simulating Ovarian Cyst.¹ I feel much indebted to that lecture, and have taken from it the following details, of which I would not otherwise have been aware.

He describes his case of a gall bladder holding 2 pints of turbid fluid, together with a number of calculi. He then discusses the whole subject, dividing these conditions into three classes:

(a) Cystic tumours of great size extending to the left of the middle line (Terrier, Lawson Tait, Gersuny).

(b) Cystic tumours filling the greater part of the right side of the abdomen, liable to be taken for ovarian cysts, fixed to that side by parietal adhesions (Kocher, Tuffell—his own case).

(c) Relatively small dropsical gall bladders associated with a second tumour of more doubtful character (Raymond, Tiescheidorf, Chance).

For the purposes of my present paper it is only necessary to refer to those under class (a), into which my case naturally falls:

1. Terrier's case readily heads the list by virtue of its truly enormous size. Woman, aged 50 years, from whose gall bladder 24 litres, or practically 42 pints, of gamboge-coloured fluid was taken.

2. The case described in this paper falls into the next place from its very large size. Woman, aged 31 years, from whose gall bladder twice there were 25 pints drawn off, and from whom at the operation 22 pints of thick gamboge-coloured liquid were taken.

3. Lawson Tait's case. Woman aged 40 years. Eleven pints of lairy liquid taken out.

4. Gersuny's case. Woman aged 50 years. Quantity not given, but an "enormous quantity of bile."

Erdmann related a remarkable case of a man, aged 24 years, from whom 60 lb. to 80 lb. of bile stained fluid was removed by tapping. As no exploratory operation was performed, owing to his leaving the hospital, the relations of the cyst remain unknown. Alban Doran suggests that "it was most probably a cystic gall bladder, but that it might have developed inside the liver as a bile cyst, the gall bladder and ducts remaining normal." For the references to these cases quoted from the lecture by Alban Doran I would refer readers to the full report of it in the BRITISH MEDICAL JOURNAL of June 17th, 1905.

The mechanics of the development in my patient of such an enormous gall bladder with so thick a wall is interesting. Apparently in some way the fall led to an occlusion of the common duct, though the specific cause is not evident. The absence of any calculi in the cyst rather negatives the probability of one or more causing the obstruction. It is to be regretted that the urgency of her bodily condition was so serious that careful examination of the liver and ducts was impossible. The tension of the bile in the hepatic and cystic ducts must have been considerable to so greatly stretch the gall bladder and hypertrophy its walls. During this time her health suffered and jaundice was present. In consequence of the drawing off of twenty-five pints the tension was reduced and the jaundice vanished although no bile was apparently entering the intestinal tract. After the first and second tapplings the gall bladder from its overstretched condition and absence of contractile power served only as a reservoir,

After the removal of the sac, gradually the sinus from the cystic duct contracted and at the same time the kinking, or other cause of the occlusion of the common duct, was removed and the bile passed into the intestine and continues to do so, as shown by the colour of the faeces.

The age of my patient was less than usually is the case where the gall bladder is much dilated. The rate of dilatation was much greater, as usually the process is a slow one. Twenty-five pints were drawn off within four or five weeks of any swelling being observed, and not more than seven months after the fall which most probably set up the condition.

SECONDARY PAROTITIS DUE TO ORAL STARVATION IN THE MEDICAL TREATMENT OF GASTRIC ULCER.

BY

H. D. ROLLESTON, and

M. W. B. OLIVER,

M.D., F.R.C.P.,

M.R.C.S., L.R.C.P.,

SENIOR PHYSICIAN,
ST. GEORGE'S HOSPITAL.HOUSE-PHYSICIAN,
ST. GEORGE'S HOSPITAL.

THE occurrence of secondary or symptomatic parotitis is well recognized as a result of abdominal diseases, especially after laparotomy for perforated gastric ulcer and in cases obviously infected, such as appendicitis, in fevers, in gastric ulcer, and in some other conditions. Stephen Paget first drew attention to the parotitis secondary to abdominal lesions in 1886, and in the following year he collected 101 cases, 50 of which were associated with some morbid condition of the generative organs. In 1904 the etiology and pathology of secondary parotitis were fully discussed by Bucknall and by Tebbs. Bucknall brought forward histological evidence in support of the conclusion that parotitis is invariably due to an ascending infection of Stenson's duct depending on oral sepsis, and that its onset may be prevented by appropriate measures. Tebbs, on the other hand, considered that in the majority of cases the path of infection is the blood stream, and not the duct from the mouth.

In the present communication we desire to direct special attention to the occurrence of secondary parotitis in the course of gastric ulcer treated medically by oral starvation so as to ensure absolute rest to the stomach. One of us (H. D. R.), after trials with other methods, such as Lenhart's and the various modifications of oral feeding, believes that the safest method as regards the ulcer, and the one most likely to be followed by permanent cure, is the somewhat Spartan one of giving nothing, not even water, by the mouth, and supplying 3 or 4 pints daily of water or (in recent years) of saline solution containing sugar, or of albumen water, by the rectum until deep tenderness over the stomach has disappeared, nutrient enemata being given in special circumstances only. The reason for depriving the patient of water by the mouth, even in sips, is of course that, since it is not absorbed by the stomach, its expulsion necessitates peristaltic action, and thus interferes with healing of the ulcer and, as has happened in some cases, may give rise to haematemesis.

The drawbacks to this method of treatment are the discomfort due to thirst and the occasional occurrence of parotitis, to which we wish to draw special attention. During eleven years' work in the wards of St. George's Hospital one of us (H. D. R.) has employed this method of treatment in the great majority of acute gastric ulcers and of chronic gastric ulcers accompanied by haemorrhage; during this period secondary parotitis has supervened in 9 cases of gastric ulcer under his care. It may be mentioned that special attention has always been paid to the mouth in the way of ordering antiseptic mouth washes in these cases, so as to avoid this complication. Such an incidence of secondary parotitis in cases of gastric ulcer treated medically by oral starvation appears to be exceptional, if we may judge from the scanty references to this subject in medical literature and from conversations with some other hospital physicians. The largest published collection of cases is that given by Tebbs—

namely, 15 cases among the cases of gastric ulcer treated medically in St. George's Hospital between the years 1890 and 1904. These cases are included in our series of 23 cases collected from the notes of cases in the hospital during the rather longer period of the twenty years 1889-1908. Paget's original paper in 1886, which summarized 60 cases of secondary parotitis, contained one case of acute gastric ulcer with suppurative parotitis, the patient surviving but never recovering her "health of mind or body." In 1898 Hone reported a fatal case of suppurative parotitis in a patient treated by starvation for gastric ulcer, and collected 8 recorded cases—Hawthorne 2 cases, Donkin 3 cases, E. A. Barton 2 cases, Nicholson 1 case. In his textbook Osler mentions that he has seen 3 cases after gastric ulcer, but as no details are given we have not counted these as due solely to oral starvation. Campbell Howard states that in fifteen years at the Johns Hopkins Hospital there were 76 cases of ulcer of the stomach with 1 fatal case of suppurative parotitis (previously recorded by Atkinson).

In the twenty years—1889 to 1908—there were 1,000 cases of gastric ulcer treated by medical measures in St. George's Hospital. As we are anxious to confine our investigation to the influence of oral starvation in the causation of secondary parotitis, we have not included any cases of gastric ulcer which were operated upon in the following statistics. Secondary parotitis has been shown to occur in a considerable proportion of cases of gastric ulcer after operation (English, Tebbs), and may then be associated with, and possibly related to, peritoneal infection. Of the 1,000 cases, 530 received food, water, or both, by the mouth from the outset of treatment, whilst the remaining 470 cases were not allowed anything by the mouth for some days after admission. Among the 1,000 cases there were 23 cases of parotitis, or 2.3 per cent., all in women; in no case was any patient affected twice with this complication. Of these 23 cases complete oral starvation was employed in 21; the two remaining cases were on rectal feeding but in addition were allowed to suck ice. In other words, the percentage of secondary parotitis in 470 cases treated by rigid oral starvation was 4.5, whilst in the 530 cases allowed something, even though only water, by the mouth it was 0.4. Haematemesis had occurred, either before admission or while in the hospital, in 16 of the 23 cases of gastric ulcer complicated by parotitis. It is thus clear that exclusive rectal feeding, or rather oral starvation, is a much more constant antecedent than haematemesis. Attention is drawn to this point because Hone attached more importance to antecedent haematemesis than to oral starvation as a factor in the causation of this form of parotitis. Probably haematemesis is likely to be a factor in the production of parotitis only in so far as it leads to treatment by oral starvation. There is no evidence that secondary parotitis depends on the occurrence in the parotid gland of thrombosis such as might be favoured by a post-haemorrhagic leucocytosis.

Of the 23 cases, the parotitis was confined to the left side in 9 cases, and in 2 cases the left side was affected first and the right side later; in 6 cases the right side only was affected, and in 1 case the right side was affected first and the left side subsequently; in 5 cases the side affected was not noted. On two occasions secondary parotitis occurred in two patients about the same time; but, apart from this, there was no evidence that it occurred in epidemic form. Of the 23 cases, suppuration occurred in 4, 2 of which were fatal; in one of these two the suppuration spread diffusely into the tissues of the neck, and was indistinguishable from Ludwig's angina. Suppurative parotitis in the course of gastric ulcer is a grave complication, for out of 8 cases of suppurative parotitis (4 from St. George's Hospital, and cases recorded by Paget, Hone, Hawthorne, and Barton) 3 proved fatal. Among the remaining 19 patients of gastric ulcer, with non-suppurative parotitis, in St. George's Hospital, 2 died.

In conclusion, we have collected 34 cases of secondary parotitis in cases of gastric ulcer, 23 from St. George's Hospital and 11 published by others (Paget 1, Hone 9, Atkinson 1). From the consideration of the exceptional number observed at St. George's Hospital, an event which we cannot explain, it appears (1) that secondary parotitis may complicate cases of gastric ulcer treated medically by oral starvation; (2) that it occurs ten and a half times.

more frequently in such cases of gastric ulcer than in cases allowed fluid by the mouth: (3) that it is an outcome of the dry condition of the mouth, and that mouth-washes do not prevent its occurrence; (4) that it is more often unilateral than bilateral; (5) that suppuration occurs in about one-fourth of the cases, and that this constitutes a grave complication.

THE PREVENTION OF PAROTITIS DURING RECTAL FEEDING.

By W. SOLTAU FENWICK, M.D.

SENIOR PHYSICIAN, LONDON TEMPERANCE HOSPITAL.

The necessary prohibition of food and water by the mouth after severe hæmatemesis is not infrequently followed by inflammation of the parotid glands, which usually develops on the fourth day after the hæmorrhage. The side first affected is determined to a great extent by the position assumed by the patient, the gland which is most frequently in contact with the pillow being first attacked. An examination of the pus obtained from the abscess shows a variety of micro-organisms, the most constant of which—the *Staphylococcus pyogenes aureus* and *Micrococcus lanceolatus*—are also abundantly present in the thick secretions of the mouth. The impossibility of keeping the buccal cavity absolutely clean in these cases permits an ascending infection of Stenson's ducts, with consequent inflammation of the glandular tissues.

When I first adopted the use of large nutrient enemata of peptonized milk (15 to 20 fl. oz.), some ten years ago, and trusted to the usual methods of cleansing the mouth, a very large number of cases developed suppurative parotitis. An effort was then made to promote a continuous secretion of saliva, with the object of irrigating the ducts, and thus of preventing an ascending infection, and with this object the patients were directed to chew horse-radish, pellitory, or pieces of raw meat at intervals, or to keep a pebble constantly in the mouth. Eventually it was found that an india-rubber teat about 2 in. in length met all the requirements of the case, and that patients were quite content to suck it for hours at a time, with the result that the mouth remained quite clean and moist. When not in use the teat is kept in a weak solution of Condy's fluid.

Since this simple device was adopted I have treated more than 300 cases of hæmatemesis by rectal alimentation, lasting from ten days to seven weeks, without being troubled in a single instance by parotitis. It is only in hospital practice, where the mouth is very foul at the time of admission, that the gland occasionally becomes inflamed before any measures can be taken to prevent it.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

OVERDOSE OF EUCALYPTUS OIL.

The taking of so large a dose as 5v or 5vj of eucalyptus oil is not of frequent occurrence. It may, therefore, be of interest to record the following facts:

About 1 a.m. on March 3rd, 1909, W. A., a man of about 55 to 60 years of age, a railway engine driver, came home from his work. He had a slight cold, and was in the habit about that time of taking six drops of eucalyptus oil on sugar, followed by what he called a tablespoonful of cod-liver oil. I was shown the spoon, and it was more like a small ladle, and I should say it would hold from

5v to 5vj. He took his six drops of eucalyptus, and put the bottle back on the shelf. He then took down in the dark what he thought was the cod-liver oil bottle, standing close to the other, but which was the same bottle containing eucalyptus oil, and poured himself out sufficient to fill the capacious tablespoon mentioned. No doubt the fumes of the six drops were still in his nose, covering the other, for it was not till he had swallowed the eucalyptus oil that by the warm feeling of it in the stomach he realized it was not cod-liver oil. He then told his wife of his mistake, but went to bed and fell asleep.

About 4.30 or 5 a.m. he awakened and felt very sick. He did not, however, vomit for some little time. When I saw him, about 8.45 a.m., he was so sick that he could not move his head or limbs, nor so much as lift up his eyelids to look at me. He had been vomiting a straw-coloured, watery, mucous fluid, which smelled strongly of eucalyptus. His skin was pale and even grey in colour. He was very cold, and could not be warmed up. His pulse was not hurried, nor small in the wave, nor high in its tension; it seemed a natural pulse of medium tension inclining to the soft side. The pupils were equal and medium in size, and reacted well to light.

By 3.30 p.m. he was very much better. He was not sick, had no headache, had a good healthy colour, and a moist clean tongue. His pulse was as before. He had slept very heavily. He had had some hiccup, breathing was never sighing.

On March 6th and 7th he still was shaken in his nerves, and did not feel "tone" enough to return to the footplate. He, however, was able to resume his usual employment in a day or two after that. He is now in his usual health.

Greenock.

KEITH ROBERTSON, M.D.

PETROLEUM IN FAVUS.

ON February 18th a woman brought to my surgery her two boys, aged respectively 6 and 10 years, both suffering from tinea favosa. The younger first began to show evidences of the disease, and it was ascertained that he had a habit while at his grandmother's house of frequently handling a cat, from which tufts of hair were falling out. His mother, before cropping his hair and applying some simple ointment, took very little further notice of the eruption until the elder began to show traces of the same disease, and whereas it spread but slowly in the younger boy's scalp, it spread very rapidly in that of the elder.

When I saw them, yellow scabs in size from a penny downwards to mere specks and having a mousy smell were thickly scattered all over their scalps, especially on the crown. The areas underneath the scabs were suppurating, and from these areas hair roots treated with caustic potash under an objective showed the parasite. I cut the hair shorter and began to depilate; but this proved so very painful, especially in the case of the roots on the outskirts of the suppurating areas, that I desisted. The usual watery antiseptic lotions (very likely from no fault in themselves) were unavailing to stop the spreading margins, although I persevered for a week or so, and one day I soaked the scalps in turpentine, in the hope that this spirituous antiseptic, by its greater penetrating quality would succeed where the watery antiseptics had failed. On the following day the skin was very inflamed and tender, and only olive oil was applied until these symptoms somewhat abated. I decided to try ordinary petroleum as less irritating but yet possessing equal, if not superior, penetrating properties. My object at first was mainly to limit the spreading margins, but after two or three applications I could see that the petroleum possessed curative properties also, and henceforth no other treatment was tried. The scalps were washed daily with soap and warm water, and after careful and thorough drying ordinary petroleum, purchased at 7d. a gallon for a store, was allowed to soak for several minutes into the skin, gentle friction being used meanwhile. A suitably fitting cotton cap as the only dressing was worn under the ordinary cap. Little or no irritation from the petroleum was observable, and in less than a month from the first petroleum bath bald patches alone remained to indicate the spots where the disease had been. They were perfectly healed.

HUGH LAWRIE, M.B., C.M., D.P.I.

Rambottom, Lancs.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

STAFFORDSHIRE BRANCH.

Wolverhampton, Thursday, April 29th, 1909.

S. KING ALCOCK, M.D., President, in the Chair.

Cases.—Dr. CLENDINNEN showed a case of amputation of the penis by Pearce Gould's method. Dr. CODD showed: (1) A case of tuberculous peritonitis treated by laparotomy and drainage. Dr. DEANESLY discussed the operation. (2) Cases of enlarged cervical glands treated by x rays, also cases of rodent ulcer and sycosis treated by the same method.

The Chest of the Elementary School Child.—In a paper on this subject Dr. BADGER pointed out the importance which Nature assigned to the correct form of a child's chest, and said that ossifying centres for the ribs were found at an earlier period than those for the vertebrae. Anatomical differences between the chests of children and of adults were explained, and sources of erroneous diagnosis as the result of auscultation pointed out. The significance of a defective conformation was considered at some length; out of 651 cases in which the conformation was examined, 246 were more or less defective; a large majority of the latter were slight defects, but 29, or over 4 per cent. of the series examined, exhibited gross deformity. The varieties of chest deformity were dealt with; it was maintained that acquired deformities, such as the alar chest and the flat chest, were due to preventable causes, and that it was a fallacy to regard them as hereditary. The rickety deformities were described; doubt was thrown upon the existence of distinct types of pigeon breast due (a) to rickets, (b) to respiratory obstruction. The influence and varieties of the latter in producing deformity were touched upon, and reference made to the fashionable symptom—apnoea; the suggestion being added that an inability to concentrate the attention upon a subject for any length of time was characteristic not only of those who suffered from adenoids, but of many others who were presumably healthy. The relation of spinal disease to chest deformity was dealt with, and various scholastic influences bearing upon this relation discussed, a case being quoted where spinal curvature in a comparatively healthy girl had been traced by the reader of the paper to be due primarily to inequality of vision between the two eyes. Various tracings and cyrtometer curves were shown.

Specimens.—Dr. DEANESLY showed specimens from the following cases: (1) *Endothelioma of the submaxillary gland*, removed from a young man. The growth had been noticed for two years, latterly growing more rapidly. It measured about $4\frac{1}{2}$ by 3 in., and was roughly ovoid in shape. On section, several small cysts lay in the centre of the densely hard tissue which formed the bulk of the tumour. It was completely encapsuled, and, though deeply connected, easily removed. (2) *Advanced tuberculous kidney from a child of 10*. This was found in the course of an abdominal section for vague right-sided abdominal pains suspected to be due to chronic appendicitis or tuberculous peritonitis. There was a history of supposed typhoid fever one year previously, but no urinary symptoms were complained of. The opposite kidney (left) felt normal on palpation within the abdomen, so no hesitation was felt in removing the affected organ. The child was recovering. (3) *Multiple stones in the kidney of a child of 8: nephrolithotomy*. The symptoms were pain in the affected loin and pyuria. A radiograph taken by Dr. CODD clearly showed six shadows. One of these was found to be due to a large stone in the pelvis of the ureter, the others to pockets or aggregations of tiny round calculi, of which twenty-four were removed. The kidney substance was healthy and not infected. The patient was recovering. (4) *Traumatic rupture of a large hydronephrotic sac*. The patient, a middle-aged man, fell from a ladder a few feet to the ground, and was admitted with the usual signs and symptoms of ruptured kidney. Operation was refused until the second week after the accident, when a huge hydronephrotic sac the size of a football, distended with bloody

urine and ruptured extraperitoneally, was removed. (5) *Small solitary villous tumour surrounding the orifice of the right ureter removed together with the intravesical portion of the latter by suprapubic operation*. The patient was a man of 74, who practically bled to death from this small tumour, and was admitted in a very exhausted condition. But for cystoscopic examination, the haemorrhage would probably have been attributed to prostatic enlargement or cancer of the bladder. (6) *An early case of primary cancer of the gall bladder treated by cholecystectomy*. The patient was an elderly woman complaining of epigastric pain after food. She made a good recovery, and remained well at present, nine months since the operation. (7) *A case of chronic torsion and strangulation of the great omentum*. A huge blue-black mass, adherent everywhere to the bowels and extending from the liver to the pelvis, was enucleated from the abdomen of a middle-aged man supposed to be suffering from chronic appendicitis. The upper stalk was twisted almost completely off, and not a single vessel had to be tied. The tumour looked like a gangrenous lipoma. The patient made a good recovery. (8) *Two cases of excision of chronic ulcer of the stomach*. Both occurred in women, and had given rise to painful indigestion for seventeen to twenty years. Excision was performed in preference to gastro-enterostomy in each case because the ulcer was solitary and because it lay near the small curvature on the posterior wall at some inches' distance from the pylorus, a position in which gastro-enterostomy generally fails to give permanent relief. The result in each case was excellent. (9) *One half the thyroid gland removed by operation from a case of exophthalmic goitre*. The exophthalmos in this case was extreme, the other symptoms moderate. The operation was followed by some diminution of the exophthalmos, and in other respects a sense of well-being which had not been experienced for years.

Treatment of Glandular Affections by X Rays.—Dr. ALFRED CODD read a paper on this subject. He said that some time ago he was very sceptical as to the efficacy of x rays in the treatment of diseased structures under the skin. The effect of different interference films had been very marked. Many cases of lupus, rodent ulcer, and ringworm that had been under treatment with x rays had always shown when there had been a scab over the diseased surface in small patches, even though very thin, that while the exposed diseased surface had readily yielded where there had been a thin film of crust or scab on the diseased surface, the cure had been considerably delayed. So, too, a film of hair had prevented the rays getting to ringworm surface, and in order to treat ringworm in minimum time, it was necessary to clean the surface well, and cut the hair well up to the margin of the disease or a little beyond it. Again, in malignant disease, where the surface was ulcerating, the substance of the growth speedily melted away, but the parts of the growth that were still beneath the unbroken skin were highly refractory to the influence of the rays. These observations led him to doubt the value of x rays in subcutaneous disease, and it was only recently that he had made a systematic effort to treat a fair number of these cases. But the results had shown that there was a large field of usefulness among these morbid processes. One of the most striking pathological results illustrative of this line of treatment was the radiographer's azoospermia, an accidental complication incidental to his work before the days of opaque screen and aprons. Here the organs were generally exposed to the rays at some distance, and with a fair screen of garments and a somewhat inadequate one of skin. But the result was very marked. The glands were markedly reduced in size, the external secretion was deprived of its living elements, apparently permanently in spite of subsequent protection, while the internal secretion was unaffected. This accidental dystrophy was illustrative of the marked result that had been effected in treatment in other glands. The cases of splenic enlargements he had treated were three in number, and all spleno-medullary leukaemia. In all cases the spleen had been enormously enlarged, the leucocytosis had been very marked, the reduction of the size of the spleen had been very considerable, the blood condition had been distinctly improved, but not markedly so, and in two cases death did not appear to be materially delayed. The reason why better success could

not be attained was that the spleen was only one of the organs whose faulty action caused the disease, but that the bone marrow was also a faulty organ or organs, whose dissemination all over the body made it almost impossible to submit them to the x rays. The following cases of *leukaemia* were related:

W. C. M., aged 35. Original notes lost. Spleen well past middle line and right down to pubes; marked leucocytosis with abundant myelocytes. Had several applications of x rays, and the spleen shrank towards the apex where the rays had been applied through a circular diaphragm. On his second admission, November 7th, 1906, the spleen had the same shape and size as when he was discharged, showing the hilum of shrinking. Its edge extended down to the pubes and to the middle line, but the artificial hilum was 2 in. from the umbilicus. Under treatment the border retreated to the left somewhat, and his condition improved. After discharge on December 5th he continued treatment for six weeks and had eight treatments. Again, from February 190th to May 23rd last year he had twenty-one applications, but during that time he did not seem to make any progress, and on June 3th he died at home. His condition was always very precarious, and it was permissible to claim that his life was made more comfortable while it continued, but it is doubtful if it was materially prolonged.

S. M., aged 66. Admitted July 14th, 1908. Spleen down to umbilicus, and slightly over the middle line, and the convexity well below the level of the umbilicus. Discharged August 31st; readmitted October 30th; discharged December 5th, 1908. The average count on November 1st was: Red, 2,464,000; white, 27,151 per c.mm. In the differential count the polymorphonuclears were 23 per cent., and the myelocytes 47.6 per cent.; haemoglobin, 60 per cent. Many other counts were taken, but not recorded on the bed-papers, but there was a general rise of red cells and fall of white cells. The spleen became markedly smaller, retreating over the middle line, and the convexity came up to the umbilical level. His general health also much improved. He had in all fifty applications. When Dr. Codd had lost sight of him, but about a month ago heard that he had died rather suddenly.

S. F., aged 37. Admitted October 30th and discharged December 1st, 1908; readmitted March 17th and discharged April 7th. On the first occasion spleen across to umbilicus, and down below level of anterior spine. Blood count: Red, 3,750,000; white, 29,000, of which there were polymorphs 31 per cent., fine myelocytes 28 per cent., large hyaline 20 per cent. On the first occasion he had twenty-two applications of x rays, and got some dermatitis, and the spleen shrank so that the mesial border was 1 in. from the umbilicus, and the lower border on a level with the umbilicus. His general health improved, and on leaving the hospital he returned to work and remained well till a fortnight before readmission, when he had a blow on his left side, and since then he felt weak, lost his appetite, and on returning to the hospital Dr. Codd found that the spleen was almost the same size as on the first admission. Count: Red, 2,500,000; white, 39,000. He had thirteen applications of x rays, but left prematurely at his own request.

Enlarged lymphatic glands were very amenable to the influence of x rays. Under this treatment they very speedily got smaller, and this progressive lessening was continued long after the rays were withdrawn. In many cases operation was a ready alternative, and had been till recently practically the only method of treatment when the glands were of a certain size and the disease was advanced. But in spite of the very assiduous care taken by some surgeons in securing the best cosmetic results, these could not be so good as those attained by the use of x rays, where all visible swelling disappeared and all the disease vanished, leaving only a tiny nodule of scar tissue, deeply buried under the skin and subcutaneous tissue, palpable, indeed, to the medical man, but such as unskilled fingers could scarcely feel it—certainly not interfering with the contours of the skin surface. The risk of anaesthetic was eliminated, and the risk of x-ray dermatitis was very remote if adequate care were taken and protection given. Of this he would speak later. But there sometimes occurred cases where the glands were so swollen and adherent to subjacent structures that it was impossible to remove them, and here was a great opportunity for the services of x rays, and in these cases there appeared to be no adequate substitute. One such case was the following:

Mrs. P., of King's Heath, came to consult Dr. Codd in October, 1906, about a hard mass in her left groin. It was of considerable size, in the position of the inguinal glands, firmly fixed to the bone, but not particularly tender, and of stony hardness. The patient was rather obese and he could not feel the femoral artery here and could not make out its relationship to the growth. There was a considerable amount of pain and walking was very painful. In the vagina there was a hard band of constriction just below the fornices, but at the close of the examination the band seemed to have relaxed and got softer, and appeared to be spasmodic in nature. Nothing was felt in the rectum nor between one finger in vagina and another in rectum.

She had consulted Mr. Christopher Martin a short time previously, and Dr. Codd wrote to him giving his views of the case. Mr. Martin kindly sent him the following note: "Mrs. P. has a curious lump on in the groin. It is, I think, glandular and possibly malignant. I do not think it any operative interference, as if it is malignant I do not think it can be safely removed. It extends under Poupart's ligament into the left iliac fossa. On its inner side it is apparently adherent to the femoral artery. It is firmly fixed to the deep fascia. I do not think that there is any malignant growth either in the vagina or rectum." It appeared to Dr. Codd to be a case in which x rays would give the best chance of remission of symptoms or even a complete cure. Owing to distance and difficulty of locomotion he only treated her once a week, though he had to have increased the frequency if there had been any signs of enlargement. Each dose was 15 min. x 1 milliamperes. There was a steady improvement, the gland became smaller, caused less difficulty in walking. On December 3rd pigmentation appeared, and a fortnight later there was distinct dermatitis and soreness, so the x rays for four applications, and then the only thing that could be felt was a small, freely-movable, and painless nodule, and walking was not interfered with. Dr. Codd had frequently seen her and heard about her since, the last time quite recently, and she had remained quite well without a bad symptom. The only other treatment since she came under his care was some iod. salicyl., iron, and nux vomica.

Another class of cases of this description consisted of those of lymphadenoma, where the glands were massed together in huge masses, which the bolder class of surgeon had attempted sometimes with success. But the great difficulty was that he never knew where he was going to end. He might succeed in taking all the glands (say in the neck) that he felt or saw, but after that there was a long string of glands running from them into the thorax and even along the thoracic duct, and there was no finality to the complete removal. Even this was not necessarily inaccessible to x rays. But the general result was that the operation did not clear away even the visible glands, and the removal was imperfect. And in such a case, the results of the case of this type in Dr. Pirie's recent paper (*vide infra*) showed what it was possible to do with x rays with patience. One case of glands evidently of lymphadenomatous (or possibly malignant) type, was admitted to the hospital from Cheshire, and owing to the onset of dementia of intractable type, the woman had to be discharged, and lives too far off for continuity of treatment. The glands, however, became discrete and much smaller. The following cases were related:

T. A., aged 5, male. Enlarged cervical glands on left side 1½ in. long. Started on February 26th, 1909, to have x rays three times a week, ten times in all, and on March 29th the subcutaneous scar of the gland was about the size of a small pea. On that date it was noticed that there were enlarged glands on the right side, and treatment was being applied to that side. No drugs.

N. R., aged 15, female. Enlarged cervical glands in large mass. Started on April 8th, 1908, with x rays three times a week; sixteen applications in all; glands completely cleared up; no drugs.

G. E., aged 5, male. Enlarged submaxillary glands, right side, 2 in. long. Started January 20th, 1909, to have x rays three times a week without filter. February 10th only very small nodule left, and pigmentation developed. On February 24th all submaxillary gland disappeared, but small nodule felt by mastoid, where it had been screened off from x rays. Had had few applications to this area since, and now this had almost disappeared, but glands had developed in the left side which were being treated. Took oil, morrhua and iron.

J. W., aged 3, male. Enlarged cervical glands on right side 1½ in. long, on left side 2 in. long. Started on February 22nd with x rays three times a week to each side, thirty times to each side in all. March 15th—right ½ in., left 1½. Now slightly less; continuing; no drugs.

A. R., aged 11, male. Enlarged submaxillary glands on both sides. Came to Dr. Codd first on February 1st, and glands rapidly increased till February 22nd, when he started with x rays three times a week. After six applications size had very much reduced. March 29th, about the size of small bean. April 16th, quite clear.

D. W., aged 7, female. Very large mass of cervical glands, 2½ in. long and very thick and broad. Started on January 25th, 1909, with x rays daily for six times without filter. Then marked redness developed and it was discontinued. Resumed on March 15th with filter, and seven times a week for thirteen times. Now the length of the mass had been greatly diminished, but it was much narrower, shallower, and softer. Still continuing. Taking iron.

A son of a colleague, aged 13, had submaxillary glands on both sides about 1½ in. in length, which had been rather rapidly growing. Started on March 29th with daily applications to each side. Treatment pressed with a view of getting appreciable effect before prolonged holiday. After seven applications the size was markedly reduced, and there was also marked pigmentation over the exposed area. He then went away for a

orntnight, and on return the glands were discrete, and about the size of small beans, and the skin had desquamated freely. Might possibly require further treatment.

G. F., aged 5, male. Very much enlarged glands of left side. Had twenty-nine applications. May, 1908, glands completely disappeared. Well since.

N. S., aged 8, female. Enlarged submaxillary glands, right side. Started on November 20th, had nine applications, and on December 16th a small nodule only just felt.

Graves's disease was very intractable. Drugs, thyroidectomy and its analogues, excision of the cervical sympathetic, organotherapy of varied kinds, all appeared to be without decisive avail. He had freely tried them all except excision of the cervical sympathetic, and the results had been very nugatory. Rest, prolonged rest, had appeared to be the most potent agent, and much of the credit the other agents had acquired might have been due to the fact that rest had been employed at the same time. Recently thyroidectomy had been done with considerable success, but it was doubtful if that success would prove permanent, and certainly the sufferer from Graves's disease was one of the worst types of patient for a general anaesthetic (local infiltration anaesthesia had been recommended for it). In this type of patient it could only justify itself by being the only possible chance of cure, and this it certainly was not. The x-ray treatment had a sound pathological basis. Graves's disease was almost certainly due to intoxication from over-secretion of the internal secretion of the thyroid, due again to hypertrophy and over-activity of the gland. If by playing on the gland with x-rays the size and the activity of the gland could be reduced, it was likely that eventually the true balance between over-activity and under-activity—Graves's disease, on the one hand, and myxoedema on the other hand—would be established. It was comparatively recently that he had begun to treat the disease, too early to get any definite results, and he had also attempted the same thing with simple goitre. He showed the cases as they were. Some showed definite improvement, small, it was true, but sufficient to encourage further efforts. He found that at first he pressed the treatment too fast, and he did not protect the exposed skin surface with any filter, and the result was that he got some severe dermatitis in two cases and reddening in others. Since he observed these changes he had tried always to use a high tube, and had used a filter of four to six layers of notepaper; this had had the desired effect. In the papers read at the Royal Society of Medicine recently Mr. Thurstan Holland stated that he always used four layers of boiler felt, and Dr. Reginald Morton said that he used a layer of lint soaked in sodium tungstate solution, and that they afforded complete protection. Probably Dr. Codd would adopt one of these methods in the future. All the cases except one had been treated as out-patients, and no special care had been taken to ensure rest, and in most cases no drugs had been given.

S. H., aged 18, female. Treatment started February 22nd, 1909. Duration one year. Before February had been attending for alopecia areata, and gland had been increasing, but during the last few weeks had been increasing more rapidly. Neck measured 12 in.; pulse, 140; fine hand tremor, skin moist, nervous symptoms. Had applications three times a week, eighteen in all. Developed pigmentation. Now neck still 12 in., but much softer; pulse, 76; no tremor of fingers still present, but nervous symptoms much less. Had been taking iron.

E. M., aged 19, female. Treatment started January 23rd, 1909. Duration one year. Marked swelling of thyroid on both sides; neck measured 15 in.; very slight proptosis; pulse, 100. Had applications three times a week, twenty-four in all; developed a small patch of dermatitis when she was not using a filter. On February 15th neck measured 14 in.; on March 29th measured 13 in.; now measures 13 in.; pulse, 80. No drugs.

K. G., aged 15, female. In-patient; in bed until last fortnight. Treatment started March 10th, 1909. Duration nine months. Neck measured 12 in.; gland swollen on both sides; tremor of fingers, marked erythema; pulse, 120 to 130. Applications daily; soon developed pigmentation. Two intervals of five and thirteen days respectively. Total applications to date, twenty-eight. After first fortnight neck measured 12 in.; next fortnight, 12 in.; now 12 in. Fourth week pulse was 90 to 120; eighth week pulse was 95 to 112.

E. R., female, aged 12. Very much enlarged thyroid both sides, increasing rapidly lately, especially on the right; neck measured 15 in.; pulse 140, eyelids and upper lip puff. Standard V at school, good memory. Stertor at night; erythema very marked indeed. Cries if looked at by inoffensive person. On February 8th began with x-rays daily without filter; after ten applications got some dermatitis with exudation, and rays stopped for five weeks. Then dermatitis cleared up, and started again with filter and three applications a week, but

visits were very irregular, total only 17. Last visit, now less erythema, more control, but neck about the same size; pulse not taken.

E. G., aged 16. Simple goitre: large thyroid (measured 15 in.), hard, pressure symptoms, dysphagia, trachea flattened. Six months' duration, increased last fortnight. Started on January 30th, 1909, with x-rays three times a week; seventeen times got dermatitis. Neck measured 14 in.

The technique of the treatment might be summed up as follows: Each application was of ten minutes' duration; a high tube was selected, generally a heavy anode Muller large-bulb tube (18 cm. bulb), fairly hard, as near as possible to 6 in. parallel spark, and always 1 milliamperé through the tube, with standard distance of 8 inches from centre of anticathode to surface of skin, four layers of stout notepaper being used as filter. In summarizing these cases, Dr. Codd said that those of spleno-medullary leukaemia were very interesting from the fact that the spleen very materially shrank up under the rays, and this was especially where a circular screen was used which exposed the whole of the lower pole of the organ but did not include the upper pole. The shrinking of the exposed area showed a marked contrast to the behaviour of the unexposed area, which remained *in statu quo*. The circular diaphragm of the author's standard instrument was used at first for convenience and safety, but after noting the above effects it had been abandoned for this purpose and a naked tube used over a masked abdomen. The results, however, could not be said to be satisfactory, though he still thought it was very useful in conjunction with rest and drug treatment; and possibly further experience, especially with a view to treating the bone marrow, if this were practicable, might lead to better results. The treatment of lymphatic glands had proved very satisfactory, although in the case of larger masses a long time was required in order to secure safety from ill effects. The most valuable contribution on this subject was the very interesting paper read by Dr. Pirie at the Royal Society of Medicine, and reproduced in the *Proceedings of the Society for March*, and some facts of great importance elicited by the paper and the subsequent discussion were the following:

Huge masses of glands due to lymphadenoma, after having had five operations performed and still leaving an immense mass, after six months of x-ray treatment, the mass appeared to have completely gone. When the glands had broken down, if the pus was simply evacuated, the gland healed in a month under x-ray treatment. Sometimes the fluid might be absorbed without opening. Dr. Manders suggested aspirating the contents when it had broken down and continuing with x-ray treatment. Dr. Charles Henton said that when visiting Bordeaux he found that all the surgeons there referred their gland cases to the x-ray department.

The cases of Graves's disease and simple goitre Dr. Codd put before the meeting had been done rather in the way of an interim report, to show the cases as they were now, hoping to be able to show them again under very much more satisfactory conditions. The cases were not the most satisfactory ones for experimental work; it would have been a better test if they had been more typical, and had had definite exophthalmos, and the various symptoms associated with that condition. The time, too, was far too short for a definite result to have been arrived at. But the value of x-rays in the treatment of this condition did not rely for its demonstration on the results shown. For that demonstration with a clear and no uncertain note he referred to the excellent and convincing paper read by Mr. Thurstan Holland, and published in the March number of the *Proceedings of the Royal Society of Medicine*. His main conclusions were that:

1. The pulse-rate was nearly always reduced, and this almost at once.
2. The tremors and nervous symptoms improved from the first.
3. The gland noticeably diminished in size in some of the cases, remaining unaffected in others; but if hard, tense, and throbbing, the throbbing diminished and the gland became softer.
4. The exophthalmos was not materially altered.

This formed an admirable summary of the cases he described, and as far as they went Dr. Codd's cases conformed to this standard. The pulse had become diminished, the gland had become diminished in some cases, while in others it had become softer and free from throbbing, and the exophthalmos had diminished or disappeared. As there had been no marked exoph-

thalmos in any of them, the effect on this could not be assessed. The results Mr. Thurstan Holland had described were not what would be regarded as striking from the point of view of histronic demonstration, but were none the less very real, and satisfactory from the patient's point of view, and in restoring the capacity for work and averting the fatal issue. The last case he described was as clear a case of the saving of life and the restoration to comparative health by treatment as could be desired. The case for the value of this treatment rested upon sound pathology. Of all the many theories of the etiology of this disease, there were none that now held the ground except that of toxæmia from increased activity of the thyroid, and the outpouring into the blood of an increased and undue supply of its internal secretion. If x rays could reduce the size of the organ, reduce the bulk of its secreting tissue, or lower the secretory activity of the epithelium without diminishing its quantity, they were on the way towards restoring the normal balance between Graves's disease on the one hand and myxœdema on the other hand. And then the crethism, which was after all the sting of the disease, was dulled or destroyed, and the tendency of the disease to incapacitate or kill was removed. It had been held that thyroidectomy proved more effectual, but whether this were so or not, the Graves's patient was the worst type of patient for a general anaesthetic. There was another line of argument bearing upon this subject which was worthy of careful attention and experimental work. Senile enlargement of the prostate was dependent on the internal secretion of the testicle, some perversion of it either in its quantity or character. When the testicles were removed, the prostatic symptoms cleared up. When the vas was removed, the symptoms did not alter, so it would appear that it was the internal rather than the external secretion that was affected. They had seen that the unprotected radiographer, by getting frequent minute doses of x rays, suffered in his external secretion without the internal secretion being affected. If, however, a more intensive application were made with the x rays to the testes, although with a smaller total dose than the unprotected radiographer received, was there not a reasonable chance that the internal secretion might be affected so as to destroy its toxic effects without destroying virility, just as they could modify the toxic influence of the thyroid secretion in Graves's disease without going to the other extreme of producing myxœdema? He thought there was a very reasonable chance of this proposal having within it the elements of success. He had just had his attention drawn to an article in the *Lancet*, by Dr. Joseph Bolton of Nottingham, on this point. He at first raised the question of the treatment of enlarged prostate by the application of x rays to the testes and to the prostate itself directly or indirectly, but finally decided that the best method was to treat the prostate directly with high-frequency currents. He then described two cases in which he had used this method with the thoughtfulness and accuracy which he always used, and certainly the results were very good and striking. His method certainly ought to be well tried. But Dr. Codd's own feeling from *prima facie* considerations was that in treating the prostate directly they were treating the effect and not the cause, and that by using high frequency instead of x rays they were using the much weaker agent. It was thus seen that all these gland affections were amenable to some extent to x -ray therapy, and in some cases complete cures had been wrought which appeared to be very permanent in their effect. He therefore suggested that the inevitable appeal to the knife in some of these cases should be reconsidered, and due care should be given to a consideration of the chance of x rays effecting the result desired in a more satisfactory manner.

A NUMBER of the members of the medical profession in Moscow have formed an association for the establishment of a private institute for the medical education of women.

THE British Balneological and Climatological Society held a very successful provincial meeting at Torquay on May 8th. The Fellows were received on their arrival by Dr. Horton, President of the Torquay Medical Society, and other medical men resident in the district. In the evening there was a dinner, followed by a concert and conversation. The proceedings included the reading of a paper on the climate of Torquay, by Dr. Thomas Dunlop, its medical officer.

Dr. MICHELL CLARKE, President, in the Chair.

Ionic Medication.

DR. H. P. TAYLER gave an account of ionic medication in general practice, quoting eight cases of rodent ulcer which he had treated by the introduction of zinc ions with most encouraging results; he also mentioned other conditions which had benefited by similar treatment, among these being granular lids, neuralgia, and diphtheritic ulcer of the external ear. Dr. LEWIS JONES described the theory of the treatment and demonstrated the migration of ions in an electrolytic solution. In a solution of sodium sulphate particles of copper from a copper electrode penetrated into a pad of porous paper from the positive electrode, while the hydroxyl group was collected at the negative. He concluded his demonstrations by instances of the applicability of specific ions to diseased conditions. Mr. J. W. MCBAIN said that ionization had led already to valuable results. Both theoretically and practically it was possible to introduce metals and salts into the tissues of the body in this way. Dr. KENNETH WILLS said that ionic treatment of rodent ulcer had given him excellent results. Not much success had been obtained in treating ulcers where cartilage and bone were involved. Mr. J. TAYLOR mentioned the benefit derived in ozaena by the use of magnesium and copper ions; he had met with a case where a child's deafness had incidentally improved while undergoing ionization of the naso-pharynx for ozaena. Dr. G. PARKER inquired whether the combination of Bier's hyperæmic treatment with ionization enhanced the local effect of the ions. Dr. ROXBURGH quoted an instance of the value of zinc ions in healing a fistula in ano which had obstinately refused to heal under surgical treatment. Mr. HEY GROVES preferred surgical measures in rodent ulcer. Dr. WATSON WILLIAMS discussed the treatment of latent diphtheritic infection by ionization, mentioning the accessory sinuses of the nose. Dr. VICKERY said he had experienced the disappointing results of ionization in cutaneous epithelioma as contrasted with its success in rodent ulcer. Dr. BOWKER gave his experience with chlorine ions in Dupuytren's contraction and the improvement resulting. Dr. NIXON described some results of treatment of papillomata and warts, saying that the naked electrode had advantages over the lint pads upon small areas. THE PRESIDENT thanked Drs. Tayler and Lewis Jones for opening so instructive a discussion. He would be sorry to think with some speakers that the character of the ions used made no difference. Electrotherapeutics had suffered from the vague way in which it had sometimes been handled; in ionization exactness was possible and should be aimed at. For instance, salicylate ions introduced into the tissues should be recognizable in the urine. Drs. TAYLER and LEWIS JONES replied.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Tuesday, May 18th, 1909.

Dr. WARD-SMITH, Vice-President, in the Chair.

Tuberculous Skin Diseases.

DR. MITCHELL, in a paper on some tuberculous skin diseases, said tuberculosis cutis vera was rare, and simply an infection from within, at the orifice of a mucous outlet. Treatment was not of much use, as constant reinfection occurred. Tuberculosis verrucosa was due to infection from without, and was somewhat rare. Treatment consisted in applying salicylic acid or pyrogallol preparations, curetting, and treating with Finsen light or x rays. Scrofuloderma was not, strictly speaking, a primary disease of the skin, but arose from a caseating gland or bone lesion in the subcutaneous tissues. Treatment consisted in removing the original focus of the disease, thorough curetting of the sinuses and ulcers, and antiseptic dressings, together with general constitutional treatment. Occasionally x rays might be useful. Lupus vulgaris was a chronic cellular overgrowth due to the invasion of the skin by the tubercle bacillus. Treatment must be both constitutional and local. Given a small patch on some part where

cosmetic effect was of little importance, the quickest and easiest treatment was that of complete excision. In cases where this was not practicable, Hebra's arsenical paste or Unna's salicylic acid and creosote plasters might be used. Curretting was practically useless as a cure, and should never be employed about the face. The x-ray treatment was the most successful of all. Dr. LANKESTER thought that the treatment of lupus by zinc ionization was very effective. Dr. EURICH suggested that in cases which did not yield readily to x-ray treatment tuberculin should be tried as well. Very often the combination succeeded where either treatment separately was ineffectual. Mr. GOYER agreed with the last speaker. He was also greatly in favour of excision where possible, and thought that scraping in many cases was distinctly useful. Dr. WARD-SMITH compared the treatment now with that of five years ago, when he was in charge of the x-ray department. Dr. LOCKERBIE asked if x-ray treatment ever caused epithelioma. Dr. BRONNER said he had been very successful with scraping combined with the application of pure formalin.

The Uses of Alcohol.

Dr. CAMPBELL, in a paper on the therapeutic uses of alcohol, said alcohol should be avoided in all cases of deficient elimination—for example, kidney disease; in all cases where a pernicious habit was likely to be acquired, as in neurasthenics and women at the climacteric; in all cases of chronic nervous depression; in all conditions where prolonged mental or muscular strain had to be undertaken; and in all cases where there was a condition likely to recur. The drug was useful when associated with food and given in small quantities (not more than 5 per cent. of the total food taken) in certain cases of anorexia, especially when connected with or caused by overfatigue—in these cases the alcohol was best taken a few minutes before food; in moderate doses, as a cardiac and respiratory stimulant, as in heart disease and bronchopneumonia; in single full doses—best given hot with a diffusible stimulant, as ammonia—very useful in late stages of pneumonia, followed by digitalis; in cases of failing compensation of the heart where digitalis was ineffectual; in full doses to produce quiet and sleep in cases of excitement, as in the delirium of pneumonia; in full doses with plenty of water, and perhaps followed by digitalis, to increase the flow of urine (only if the kidneys were healthy).

GLASGOW SOUTHERN MEDICAL SOCIETY.

Thursday, May 13th, 1909.

Mr. GRANT ANDREW, President, in the Chair.

Lymphadenoma.

Dr. JOHN ANDERSON introduced a discussion on lymphadenoma, showing by the epidiascope that the gland lesions presented a distinct histological picture. In the earlier stages there was proliferation of the lymphoid cells, increased vascularity, and proliferation of the reticular epithelium, while the lymph sinuses were somewhat dilated, and showed the presence of small and large lymphocytes, epithelioid cells and eosinophiles. In the more advanced stages the reticulum was coarser in character and increased in amount. Bands of fibrous tissue were seen traversing the gland in an irregular manner, while varying amounts of small and large lymphocytes, plasma cells, large uninuclear and multinuclear giant cells completed the picture. He regarded the lesion as of the nature of a chronic inflammation of unknown etiology.

Dr. T. K. MUNRO dealt with the history, symptoms, diagnosis, and treatment of the disease. Its duration varied considerably, from weeks to many years. Diagnosis in the early stage might be impossible. Examination of the blood was valuable in excluding leukaemia, but as the composition of the blood varied, a diagnosis could not be based upon this alone. As regards treatment, when the glandular enlargement was localized, surgical treatment was rational, though frequently recurrence took place. In many cases surgical treatment was necessary from the complications produced by the pressure of the enlarged glands. He believed arsenic to be the most reliable internal remedy, and had seen much benefit from its use. He had also used x-ray treatment in addition for some time, and had sometimes seen an enormous improvement in the size of the glands after a few applications.

Professor STOCKMAN considered that the glandular enlargement was only a symptom, and that there was some underlying condition which would probably be discovered. He used arsenic for treatment with considerable benefit at times. He instanced a case of the disease which had lasted for twenty years, and the patient was still alive and in good health.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Friday, May 21st, 1909.

Sir PATRICK MANSON, President, in the Chair.

Adjourned Discussion on Beri-beri.

Dr. C. W. DANIELS said that Dr. Braddon, whose theory they were discussing, had rightly laid much stress on the fact that in the Malay States there were several rice-eating races, and that one of these—one which prepared its rice in a different way from the others—was immune from beri-beri. The question of the preparation of rice had been prejudiced by the use of inexact terms; there was, for instance, a great difference between fresh rice and freshly-husked rice. The so-called Indian rice eaten in Malaya did not grow in India, nor was it prepared or "cured"—to use Braddon's term—in the same way as rice was in India. It was mostly grown in Siam, and was cured in Penang by being steamed or heated for seven or eight minutes; it was not boiled until the grains split, and during the whole process it was never warmer than a hot poultice; this alleged sterilization was carried out after a lengthened soaking in water, during which the grain often sprouted. The result was anything but sterilization. So-called Indian rice not only looked dirty, but was dirty and mouldy; it was full of dust, and he himself had cultivated innumerable moulds and bacteria from it. The Chinese said that it gave them dysentery, and that they could not eat it on that account. On the other hand, the uncured rice which the Chinese used looked, smelt, and tasted excellently, and appeared to be wholesome and appetizing. With regard to statistics, there had been variations in prevalence quite as great before the cured-rice days as there had been since. In Penang Gaol Rangoon rice was used for many years without beri-beri; suddenly, in one month, 35 cases occurred, most of them fatal. Why did the rice, alleged to be unwholesome by Braddon, take years to affect the prisoners? Again, cases originated in gaols almost immediately after admission of the prisoners; these could not be due to chronic poisoning. With regard to beri-beri in ships, he was quite unconvinced by Professor Holst's arguments that it was a form of scurvy. Uncured rice, which Braddon alleged to be the cause of the disease, was used everywhere—in England, on board ship, and all over the world—and if Braddon's views were true, it ought to be excluded from our households. Sir WILLIAM TREACHER, K.C.M.G., said that his somewhat extensive experience as a layman left him with an open mind on the subject. The feeding experiments certainly supported the rice theory, but most of them would remember instances in which beri-beri affected only one class of a community, all of which ate the same food. He recollected that in Labuan a company of Mohammedans (Malays from Ceylon) were stationed as a guard, and that they were attacked by virulent beri-beri, and almost the whole of them died. None of the other inhabitants had the disease, although all ate the same rice, which was brought from Singapore in a sailing ship. Mr. T. P. BEDDOES said that on the Amazon, where no rice was eaten, beri-beri was prevalent, and that the type was malignant. The principal food was cassava, prepared from the root from which tapioca was derived. Dr. HARTIGAN said that in different schools in Hong Kong in which the food was exactly the same, there had been a wide variation in the incidence of beri-beri. Some schools were badly affected; others were not. Dr. H. MACFARLANE said that at St. Paul's College, Hong Kong, there were outbreaks of beri-beri among the students every year, and that all sorts of rice had been tried without effect. Change of place, and not of diet, had arrested the disease. Professor RONALD ROSS, C.B., said that it was most important that the question should be taken up in earnest now that a prima facie case had been made out, and that further feeding experiments conducted

on more exact and searching lines should be initiated. Sir PATRICK MANSON said that the weight of opinion amongst those who had spoken in the discussion was opposed to the rice theory of the origin of beri-beri. Still, many capable observers had deliberately adopted the hypothesis after having opposed it. The society would hesitate to say definitely that these men were wrong; but until they had more facts at their disposal, his own position was one of suspended judgement. Dr. F. M. SANDWITH afterwards called attention to a paper forwarded by Dr. Stanton of Kuala Lumpur, which was written by J. Bontius of Batavia in 1624, and in which the disease was fully described. Bontius's volume, *De Medicina Indorum*, lent by the Royal College of Physicians, was also shown.

Pneumonic Plague.

A paper on the epidemiology of pneumonic plague was read for Captain Gill, I.M.S., Assistant Plague Officer, Lahore. It stated that pneumonic plague in all its stages was intimately connected with the bubonic variety of the disease, but that it had definite and well-marked epidemiological characters. When it occurred as an original infection it was associated with a preceding rat epizootic in the same way as bubonic plague. Further, an outbreak of pneumonic plague tended to die out quickly; sometimes it was succeeded by a bubonic epidemic, but at other times no bubonic plague appeared. The mode of spread was direct from man to man, but rats were extremely easily infected by human patients, and a rat epizootic was started, which in turn gave rise to an epidemic of bubonic plague. Pneumonic plague was, further, only seen at the commencement of the epidemic season of plague, and in almost every outbreak there had been pneumonic plague at the beginning. In estimating its effects it should be remembered that it was liable to start bubonic epidemics, and that it was in all probability the expression of an unusual or exalted degree of virulence of the plague bacillus. If any variety of plague ever again prevailed in Great Britain it would be the pneumonic form. A decrease in the prevalence of pneumonic plague was likely to be one of the earliest signs of the decline and final disappearance of plague epidemics in India.

Reviews.

PSYCHOLOGICAL MEDICINE.

SOME years ago, in 1902, Dr. Paul KRONTHAL wrote a book upon nerve cells and cells in general,¹ which, by the novelty of the views therein expressed—views in direct conflict with the neuron theory which at that time was almost universally accepted—and also by the amount of evidence adduced in support of his contention that the nerve cell, so-called, was not a true cell, but a composite structure or agglomeration of fibrillae and wandering cells indistinguishable from leucocytes, attracted considerable attention. Since this much of the internal structure of nerve tissues has been laid bare by APATHY, BOTHE, RAMON Y CAJAL, and others, and a new work by Dr. KRONTHAL on nerves and mind² will probably encounter less opposition, even if all of the author's views are not likely to be accepted. The book is divided into two parts, the first containing a description of the minute anatomy of nervous tissues with his interpretation of their origin and internal relations; and the second part treating of mind—or, as the author would say, "the sum of reflexes"—viewed in the light of his anatomical explanations. It would be impossible to give in brief space an adequate account of Dr. KRONTHAL's carefully thought out analysis of nervous structures, but it may be said that, according to his exposition, the conducting paths or fibrillae constitute the only true and essential nervous mass, and that the remaining parts of the nerve cell—that is, the protoplasmic and chromatin masses, nucleus and nucleolus—belong to the wandering or neutral cell, which bears the same relation to the neuro-fibrillae that a drop of oil does to a number of threads at whose intersecting point the drop has become entangled. There is, according to the author, only this difference: that inside the cell the insulation

of fibril from fibril is removed, the cell thus forming a switch or communication between the fibrillae. For the author's interesting demonstration of how cell form is determined absolutely by the number and direction of the fibrils meeting at that point; for his captivating elucidation of Wallerian degeneration; and for his destructive criticism of the theory of the dominance of the nerve cell we must refer readers to the book itself. Obviously Dr. KRONTHAL's main tenets, if true—indeed the main facts only, if true—involve the death of the neuron theory, a conclusion to which neuro-histologists generally appear to be leaning. The limits of space prevent at the moment any further discussion of Dr. KRONTHAL's eminently logical and searching treatment of the later part of his subject, or of the classifications and analyses of types of nervous disorder—using the term in its widest significance as including mental diseases. We need only say that Dr. KRONTHAL marshals a very great amount of evidence in support of his original views, which he expresses throughout with admirable clearness and definition, with a thorough grasp of his subject, and with unusual width of philosophical outlook.

A paper on the methods of examination of the intelligence, which was read by Professor ZIEHEN of Berlin at the International Congress for Psychiatry two years ago at Amsterdam, has been enlarged, and is now separately published, its subject being defined as the principles and methods of testing the intelligence.³ The monograph is limited to a discussion of the methods of proving in any individual case the normal or abnormal capacity for ideal presentations, their associations and elaborations. Professor Ziehen treats of his subject under the headings of: (1) Retention or deposition; (2) development and differentiation of ideas; (3) reproduction; and (4) combination. The whole paper covers only 61 pages, and is throughout simple and practical. Under "retention" Professor Ziehen alludes to the scanty value of school knowledge, such as the answers to questions in geography, etc., as a means of testing the stock of ideas, for what is required of man is a knowledge of those facts which are of value to him in his daily life; but, since these facts vary with each individual, the examination of the individual should be conducted along the lines of ascertained information concerning him. A uniform method of examination, therefore, is undesirable and likely to give inaccurate results. Professor Ziehen, however, gives a few examples of methods of testing the retention of number, form, narrative, etc., which are, in his opinion, free from the errors which lurk in most. In treating of the development and differentiation of ideas the author outlines and illustrates the processes he has called isolation, complexing, and generalization. These three processes have been explained by Professor Ziehen elsewhere (*Leitf. d. phys. Psychol.*, 7 Aufl., 1906), and he therefore contents himself in the present paper with examples. A child, for example, who out of the idea-complex of the touched, tasted and seen sugar draws the idea of "sweet," offers an illustration of isolation; one who from the thunder, lightning, and rain obtains the idea of "storm" shows complexing; and one who from many single sweet tastes obtains the idea of "sweet," or from many repeated storms derives the idea "storm" gives an example of generalization. Professor Ziehen then gives examples of the questions which may be addressed to the patients to disclose which of these processes may be defective, all of which, though simple, have been carefully selected for the particular end in view. In speaking of reproduction he draws a distinction between two groups of ideas and associations: (1) those which always are at disposal, like current coin, and (2) those which are only reproducible in particularly favourable circumstances or with definite constellations of ideas, the bills and banknotes of thought. He attaches considerable importance to this distinction in diagnosis; for instance, epileptic dementia affords a distinguished example of special defect in the first group, thinking becoming monotonous and limited by its restriction to the nearest and most trivial associations. To the last and most important process of combination, by which new series of associations are produced, most space is properly given,

the various simple and most easily practised methods in common use being discussed—the various “completion methods,” in which all the factors of a series but one are given and the patient set to find that one, whether in number, form, narrative, or bodily exercises; the Ebbinghaus method, Bourdon’s test, and so on. The essay is not intended to be an exposition of the whole subject, but is merely a survey of the main points of those methods of examination which the author has proved to be of value in his practice in this particular matter, and is well worth reading.

Professor STÖRRING, in his book on mental pathology and normal psychology,¹ in describing the constituents of self-consciousness, speaks of “activity-feeling,” or the awareness of present mental acts, as “the condition of our regarding the spiritual self as within wide limits independent as against the material world,” and as also determining the content of the consciousness of self. In a paper read recently before the Prague Philosophical Society,² on the activity-feelings, the author, Dr. Löwy, Clinical Assistant in the Prague University Psychiatric Clinic, takes Störing’s description of patients who are apathetic about all that happens to them; who have lost the feeling of activity or effort that used to accompany their thoughts and actions, and so seem to themselves like lifeless machines, as a text, which he illustrates by a case under his own observation, with allusions to numerous others exhibiting the same loss of activity-feeling. Dr. Löwy’s patient was a highly-educated Russian girl, a university student, who some months after a powerful emotional shock developed neurasthenic symptoms and passed through three emotional phases—pleasurable, disagreeable or painful, and finally indifferent—which extended over four years, and ended in recovery. Her symptoms, apart from their affective colouring, were those of neurasthenia and psychasthenia, and comprised, amongst an infinity of others, headache, nightmares, dreams of for ever saying words different from what she intended, the attachment of a prophetic character to her dreams, compulsory counting, arithmomania, and numerous other obsessions, kinaesthetic and hypnagogic hallucinations, and numerous phobias, for example, fear of being watched, of being looked upon as an enemy, etc. At no time had she delusions, always recognizing the strange and absurd nature of her fancies and impulses, and at all times prompt and accurate in her answers to questions, disclosing a sound judgement and lucidly discussing complicated philosophical questions. The main theme of Dr. Löwy’s discussion, however, turns upon the three affective phases passed through by his patient. The first of these was distinguished by pleasurable feelings of detachment from the material world, including her own body, and of heightened mental penetration; the second by painful feelings of extinction; and the third by complete emotional indifference, for, though conscious of her bodily and mental existence and affectively aware of her body, her mental processes had no complement of feeling, so that her thoughts appeared to have no connexion with herself, self-consciousness being thus largely annulled. The whole of these phases and the neurasthenic symptoms manifested during the course of the disorder, Dr. Löwy endeavours to show, depend upon pathological alterations in the “feeling of activity,” which may be general in character or affect only particular processes—memory, reproduction, perception, and so on. This loss or alteration of activity-feeling, which is, he says, at the bottom of many phenomena frequently met in mental disease, outside simple depersonalization—impulsive feelings, feelings of doubt, etc.—he has found in the great majority of cases to occur not in the psychoses but in the neuroses.

Under the fascinating title of idealism as life-sustaining principle,³ Professor JAROTZKY, of the University of Dorpat, has written a book which teems with information which is always interesting and suggestive, but tantalizingly elusive and disappointing whenever the reader imagines

the author is at last going to come to the point, to grapple with his proclaimed subject-matter, and advance proof or even well-conceived theory of the influence of an idealistic mental habit upon bodily processes. He begins well. After a succinct account of modern advances in therapeutic art and science, and a statement that the two great levers by which modern medicine has been elevated to its present plane are, first, the conception of living matter as a mechanism whose functions are explicable by the same processes investigated in the inorganic world by physics and chemistry, and, secondly, experiments on living animals, and after describing and extolling the great benefits which have been obtained in these ways, he makes his first point, which is that modern medicine as its scope and method are regarded by some, does not differ from veterinary medicine and surgery, and that any capable veterinary surgeon (*Tierarzt*) could undertake, with perfect honesty of purpose, the treatment of man. This Professor Jarotzky attributes to the neglect or denial of the influence of mental events on bodily processes, and the prevailing conceptions of the human body as a machine. Professor Jarotzky sets out to combat this bogey of his own imagining. By idealism, which is nowhere defined in the book, we gather that he means lofty imaginings and aspirations; a love of truth and beauty; a firmly altruistic and self-sacrificing morality, and a settled theological faith. Professor Jarotzky’s idealism is thus not philosophic idealism; nor when he appraises mental influences does he descend to the base level of hypnotism, which “never raises the moral forces of the mind, but unfolds only the ignoble phases of the emotions; which lowers the level of mental activity; limits the field of consciousness; paralyses the resistance of the patient, and damages the whole moral personality.” The book also abounds in such statements as that intense fright sometimes brings about recovery in severe nervous diseases, and at others initiates the first changes of organic disease, but with never a word of proof. Notwithstanding all this, and notwithstanding the fact that the author never even attempts to supply any foundation to his oft-reiterated affirmation that “the highest idealistic phases of the mental life are the chief factors which dominate the whole physical cycle of the life of man; which decide the duration of his span of life, and determine the higher or lower degree of morbidity,” his book contains many points of interest to the speculative mind. Amongst these is a sketch of the economic and sanitary conditions of the Russian proletariat. Whilst it is impossible to attach any scientific value whatever to the work, it is equally impossible to read it without sympathy and admiration.

Dr. MOLINÉ, the author of a small book on the great question of brain and mind,⁴ is an orthodox dualist who has been struck by the trend of modern thought towards a monistic interpretation of vital phenomena, and in particular towards mechanical materialism. Admitting with Haeckel an eternal and infinite substance, he refuses to accept cosmic matter as an integral part of that substance. The author’s doctrine of bio-animism conceives the human mind as “a faculty of high differentiation, as a superior polarization of energy which co-ordinates and unifies”—informing the body, as Aquinas said. Only, this high differentiation, instead of being an inherent and progressive necessity of living matter, is the result of a special intervention of Providence, that is, the author discards entirely any teaching of an immanent Deity in favour of Christian revelation.

GASTRO-INTESTINAL DISEASE.

IN his monograph on fat absorption Dr. KOSTER⁵ has employed the histological method to elucidate the problem which has hitherto been attacked chiefly by chemical means. He has investigated the absorption of fat in the colon as well as in the small bowel, using various kinds of fat material such as emulsions of oil or simple cream or soap, with or without the addition of bile or pancreatic

⁴ *Analytique de l’Esprit humain et de la vie (Bio-Animisme)*. By Dr. J.-A. MOLINÉ. Paris: Vigot Frères. 1907. (Cr. 8vo. pp. 128. Fr. 2.)

⁵ *Fettresorption im Darne und Gallenabscheidung nach Fütterung*. Von Prof. Dr. Med. Georg Koster. Leipzig: Dr. Werner Klinkhardt. 1908. (Med. 8vo. pp. 104. Taf. 6. M. 8.)

preparations; in particular he speaks of a certain German preparation as having given favourable results. With regard to the power of the ileo-caecal valve to prevent fluids passing upwards into the small bowel he found in six experiments on animals that the fluid did not pass the valve under low pressure and only when undue pressure was used did this occur. His results strongly confirm those of others as to the capacity of the colon to absorb fat; as much as 50 to 80 per cent. of cream was absorbed when the pancreatic preparation had been added to it. His experiments on dogs with biliary fistulae give no support to the statements that oil or fat acts as a cholagogue, but whether given by the mouth or by the rectum it induces the gall bladder to discharge its contents. The mechanical theories of fat absorption receive no help from Dr. Koester's histological observations, but the view of Pfleger and others that the solubility of fat in water is an essential condition of its absorption by the intestinal epithelium is confirmed. He believes the process consists of the splitting of the fat into fatty acid and glycerine by the seapsin of the pancreatic juice, while the bile partly dissolves the fatty acids and partly forms soluble soaps by combining them with taurocholate of soda. He thinks emulsification only aids the process by dividing the fat into fine droplets. The lipase of the intestinal juice is an important fat-splitting ferment, but it acts only on emulsified fat. His experiments and observations afford no evidence of fat absorption in the stomach. Exclusion of bile from the bowel did not affect the absorption of fat, but when both bile and pancreatic juice were excluded there was only very slight evidence of absorption, and that only in the neighbourhood of the ileo-caecal valve. He thinks the practical results of his observations go to show that rectal injections of oil are valuable, as they pass right up to the ileo-caecal valve, and are consequently of great use in softening hard faeces and relieving obstinate constipation. In the treatment of gall stones, although oil does not act as a cholagogue, it may be of use by emptying the gall bladder, and thus preventing the stagnation of bile. He does not think the oleate of soda (eunatrol) has any advantage over simple emulsions of fats. He lays stress on the importance for rectal feeding of the evidence of the power of the colon to absorb fat, and thinks that the effect of the addition of pancreatic preparations in promoting absorption should not be forgotten. The essay is illustrated by a number of microphotographs and coloured drawings, showing the fat in the wall of the intestine.

We noticed Dr. PAUL COHNHEIM's book on *Diseases of the Digestive Canal* on the appearance of the first edition (September 30th, 1905, p. 812) and again when the second German edition was published (December 14th, 1907, p. 1717). The general scope of the work was then described, and a high opinion expressed of the method upon which it was planned. We are therefore glad to welcome a translation of the second German edition by Dr. DUDLEY FULTON, Lecturer on Medicine in the University of Southern California, Los Angeles.² Our appreciation of Dr. Cohnheim's work must not be taken to imply complete agreement with all he says; he is not, in fact, always in agreement with himself; for example, we could not agree with the statement on page 19 that vomiting is never absent in actual dilatation of the stomach; or with that on page 2, that pain occurs exclusively in organic diseases of the stomach. He includes as painful all sensations of a cramping, colicky, cutting, stabbing, or burning nature, yet on page 169 he says, "The subjective symptoms of hypersecretion consist of burning, boring, and rarely cramp like pains in the epigastrium"; and in his description of gastric crises he says, "These attacks are often accompanied by most severe pain" (page 226); yet neither is an organic disease of the stomach. We differ from him in the opinion that "the gastralgia of neurasthenia never amounts to true pain." For some reason Dr. Fulton invariably prints "enteropticus" instead of "enteroptoticus," and repeats this wherever the adjective recurs, whether concerning the stomach or the intestine, although the German version gives the word correctly. "Stomach-stiffenings"

can hardly be regarded as a happy description of those alternate bulgings of the stomach or slow peristaltic movements seen in certain cases of pyloric obstruction. "Contracted liver" is not a good equivalent for *Schnur-leber*, meaning the "constricted" liver generally attributed to tight-lacing, but which Dr. Cohnheim says is rarely met with in women who wear stays, but is caused by the tight drawing of the strings by which the skirts are held in position. "Estalin" is said to be the latest remedy for haemorrhage, but is a misprint for "Escalin," and its supposed value has been denied by Ewald and others. We are glad to see that the translator takes a more enlightened view of the need for seeking early surgical assistance in cancer of the stomach than that expressed by Dr. Cohnheim. The translation is generally well done; but, in addition to the points already mentioned, we might point out that *Heidelbeer* (p. 262) is not blackberry, that *Hammelfleisch* (p. 269) does not mean "ham," and that, though "noodles" may be the American for "vermicelli" (*Nudeln*), it is a word in this significance unknown to us. May we add that the diagrammatic illustrations based upon photographs of naked women have no advantage over the usual outlines, and in other respects are objectionable.

A review of the original French edition of Dr. COMBE's work on intestinal autointoxication was published in this JOURNAL some time ago (December 14th, 1907, p. 1718). The volume entitled *Intestinal Autointoxication*,¹⁰ and prepared by Dr. STATES, is called not a translation, but an adaptation, presumably in order to give the translator greater freedom. Professor Combe, instead of attributing the causation of all diseases to uric acid in the blood, holds a similar view with regard to absorption of toxins from the intestine, but he comes very closely into harmony with Dr. Haig in the matter of treatment, as his dict, which is to constitute an almost universal panacea, is very much on the same lines. The diagnosis of autointoxication in cases in which there is no obvious intestinal disease is to be made by a somewhat complicated method for estimating the quantity of sulpho-ethers in the urine. The treatment is a lacto-farinaceous diet, no fluid being taken with meals. Combe also advocates the use of sour milk and of yeast to diminish intestinal putrefactions, but he has a very catholic belief in other remedies, including antiseptic drugs; preparations of the extracts of the various organs, such as the pituitary gland, the suprarenal capsules, the liver, and the thyroid; and he includes the various "natural" remedies—mineral waters, sun baths, and air baths. The volume concludes with a chapter on the lactic ferments, written by Dr. Fournier. The work of translation or adaptation is fairly well done, but the style is not very easy, and the text is disfigured by a very considerable number of slips in grammar and in spelling, especially of proper names.

GONORRHOEA.

IN *Gonorrhoea in Women*,¹¹ Dr. PALMER FINDLEY makes a summary of all the questions associated with his subject, in the hope that his monograph may serve in its way to instruct some and to awaken all to a greater realization of the great importance of the subject of gonorrhoea in women. The detection of the gonococcus in chronic or doubtful cases is, he insists, essential, and so important, in his opinion, is the recognition of that microbe that he dedicates his book "To Professor A. Neisser, the discoverer of the gonococcus." He dwells at some length on the moral and social aspect of the disease and its causes. It is sad to find how prevalent it is and how disastrous are its effects in the great Republic, just as in Western Europe; unfortunately the reasons are evident, though the remedy is far from clear. Dr. Findley admits that Noeggerath's deductions from personal observations are quite justly regarded as extravagant and unwarranted; indeed, another writer once argued that Noeggerath so overstated his case that without knowing it he implied that gonorrhoea rather promoted

² *Diseases of the Digestive Canal*. By Dr. Paul Cohnheim. From the Second German Edition. Edited and translated by Dudley Fulton, M.D., Philadelphia and London: J. B. Lippincott Co. (Med. 8vo, pp. 393, 16s.)

¹⁰ *Intestinal Autointoxication*. By A. Combe, M.D. English adaptation by W. G. States, M.D. London: Reban, Limited, 1908. (Roy. 8vo, pp. 479, 16s. 6d.)

¹¹ *Gonorrhoea in Women*. By Palmer Findley, M.D., Professor of Gynaecology in the College of Medicine of the University of Nebraska, Omaha, etc. St. Louis: The Mosby Medical Book and Publication Company, 1908. (Sup. roy. 8vo, pp. 112)

fertility, since he maintained that over three-quarters of the husbands in a town where the population was increasing had suffered from gonorrhoea, whilst three-fifths of their wives were infected. Checks on impregnation have to be taken into account, though we are aware that increase in population in the case in point is largely due to fresh immigrants rather than to native babes. Doctors, however, cannot remove the social wants that sin against the strength of youth, nor many other prejudicial conditions which retard or corrupt matrimony in modern nations. Dr. Findley agrees with the view that medical regulation and supervision of prostitution are inadvisable, inadequate, and promotive of a false sense of security from infection. Neither the author, nor any other authority, however, has suggested any remedy, legislative or otherwise, that is likely to remove the curse of this and other varieties of contagious disease. The medical aspect of the question is not so gloomy. At least we know, according to Dr. Findley and his American colleagues, that to determine the infectiousness of a given case we have but to recognize the gonococcus; at present we cannot discriminate between that germ when of high and when of low virulence, and we know that it may lie latent for years and then light up what appears to be a new and acute infection or may transmit a virulent infection without becoming manifest itself. Hence we must know how to find the gonococcus, we must be familiar with the conditions which foster or destroy it, and, lastly, after gaining that knowledge, we must endeavour to stop gonorrhoea in women at its source. In other words, we must make sure it is cured in the male, that is to say, in the husband or the suitor who asks his doctor if he be fit to marry. The total absence of the gonococcus after stringent test alone justifies a favourable verdict. Hence Dr. Findley makes much of the gonococcus and gives full references to authorities who have written on its bacteriology, which he himself summarizes in this monograph. There is, unfortunately, some discrepancy amongst experts as to power of resistance against desiccation. Kratter and McFarland make out that the gonococcus shows remarkable vitality even in dried secretions, others are of a contrary opinion. And Dr. Findley himself speaks of the early death of the germ in dried secretions, and observes that it is comparatively rare that gonorrhoeal infection is acquired by means other than sexual intercourse for the reason that the secretions when dried are innocuous. The question should be settled, as its importance is obvious. The relative gravity of gonorrhoea in the female is now well recognized, though forty years ago it was all but entirely overlooked. Dr. Findley rightly insists on its ravages—ophthalmia, pyosalpinx, peritonitis, constitutional symptoms, etc.—and reminds us that, as has already been written, in the case of gonococcal infection the individual risks which a wife is made to incur are much more serious than those following syphilis. The puerperium is certainly endangered, and the risk of blindness to the infant is very high. Couvelaire, perhaps the best authority on the histology of the gravid tube, believes that inflammatory changes are the result, not the cause of tubal gestation, and so would deny the gonorrhoea theory. Lastly, Dr. Findley admits that more progress has been made in the etiology, pathology, and diagnosis of gonorrhoea than in its treatment, but he adds full directions for the management of cases, and discusses the vaccine treatment of gonorrhoeal vulvo-vaginitis in children. Thus, as we have shown, this work is a handy and complete summary of a very grave subject.

We have read Dr. W. G. M. BYERS'S *Study of the Ocular Manifestations of Systemic Gonorrhoea*¹³ with great interest and profit. The author has collected and presented in a readable form all that is known to-day about this important subject. One of the earliest accurate descriptions of gonorrhoeal irido-cyclitis was given in 1830 by Sir William Lawrence. Mackenzie described the condition fully, and his views still influence our conception of the disease at the present day. Dr. Byers, after a historical retrospect and some general considerations, takes the tissues of the eye seriatim, and describes how each may be affected by metastatic gonorrhoea. His remarks upon metastatic conjunctivitis are very important to the general prac-

titioner, for it is a disease which is constantly—one might say almost always—overlooked. The monograph is well printed on good rough paper. A full bibliography is appended.

The small work on the diagnosis and treatment of gonorrhoea in the male by Dr. S. JESSNER of Königsberg¹⁴ forms one of a series of dermatological essays for medical practitioners. The author does not advocate the energetic and aggressive instrumental treatment of acute gonorrhoea adopted by some recent authors, and writes in a moderate and practical manner which should ensure his book a favourable reception both by practitioners and students. Dr. Jessner speaks well of ichthargan in the earlier stages, when the inflammation is not too severe. Protargol, he thinks, often increases the discharge. For chronic gonorrhoea he considers that silver nitrate and copper sulphate give the best results when intelligently and carefully adapted to the needs of each case. Of the numerous books on this subject which have appeared in Germany and Austria of late years this is one of the best we have seen, judged from the point of view of the general practitioner.

NOTES ON BOOKS.

TRAVEL is one of the most favourite forms of recreation with medical men, but each kind of travel calls for a special kind of information. To many the motor car has opened up delightful opportunities of seeing their own and foreign countries which the railway could not afford. For them the old guide books are a little out of date, since they do not give the information about roads and intermediate places which the motorist needs. Probably most motorists, who have toured in France know the *Guide Michelin pour la France*,¹⁵ and for them it will be sufficient to say that we have before us the edition for 1909 (in French). For others we may add that it is perhaps the most thoroughly practical guide book that has ever been compiled. The towns, including quite small market towns and even villages, are arranged in alphabetical order; the routes from each place are specified, with the distances and hints as to the gradients and surfaces. The hotels are enumerated, and by the use of conventional signs much information is given about them, and the chief buildings of historical interest are indicated. The volume includes a map of France in 67 sections, and a key indicating the main roads and the section of the map in which full details are to be found. The book is, of course, an advertisement of the tyres made by the Michelin Company, of Clermont-Ferrand, and, among other places, London (44, Sussex Place, S.W.), and if gratitude resides in the motorist's breast the company ought to have its reward.

The little book *How to Become a Naval Officer*,¹⁶ which Messrs. Gieve, Matthews and Seagroave (21, George Street, Hanover Square, London, W.) will, we are informed, be pleased to forward to any parents thinking of the Navy as a profession for their sons, appears to be just what its title professes, and Admiral Fremantle in a short introduction states after an examination of the volume, that the information given in it is thoroughly reliable. In Part I, the Admiralty regulations as to naval cadets are printed; in Part II there is a description of life at Osborne, and in Part III of life at Dartmouth College, to which the cadet goes after two years at Osborne. Part IV is a lecture by Professor Ewing, C.B., Director of Naval Education, on the new scheme of naval training, illustrated by a most curious "diagram of promotions" which looks like a transverse section of a barge. In an appendix some miscellaneous information is given, including the list of the articles in a naval cadet's kit. The volume is copiously illustrated by photographs of Osborne and Dartmouth, and has for a frontispiece a portrait group of the Prince of Wales and his eldest son in naval uniform.

¹³ *Diagnose und Therapie der Gonorrhoe beim Manne*. Von Dr. S. Jessner. Würzburg: A. Stuber, 1909. (Demy 8vo, pp. 164, M. 3.)

¹⁴ *Michelin-guide*. Clermont-Ferrand, Puy de Dôme, France (1 fr. 50c. Post free.)

¹⁵ *How to Become a Naval Officer, and Life at the Royal Naval Colleges at Osborne and Dartmouth*. Revised edition. London: Gieve, Matthews and Seagroave. (Cr. 8vo, pp. 76.)

UNDER the will of the late Mrs. Lucy Jane Grice, of Forest Row, Sussex, the Newport and Monmouthshire Hospital receives a bequest of £5,000, and the West Bromwich District Hospital and the Reigate and Redhill Cottage Hospital each £1,000.

¹⁴ Studies from the Royal Victoria Hospital, Montreal, vol. II, No. 2 (Ophthalmology, 2). *A Study of the Ocular Manifestations of Systemic Gonorrhoea, with Reports of Cases of this Nature*. By W. G. M. Byers. Price 5s.; to be obtained from the Secretary of the Hospital.

THE COMPOSITION OF SOME PROPRIETARY FOOD PREPARATIONS.

II.—Tonic WINES.

In addition to the meat wines already dealt with, a large number of medicated wines are advertised and sold for employment as tonics in convalescence after illness and at other times. The particular medication employed, whether cinchona, coca, phosphates, or some other, is mentioned on the label or in advertisements in most cases, but not in all. Analyses have been made of a number of these wines, and the results are here given; there is no reason to suppose that others differ greatly from those described.

Following the usual analytical practice in regard to wines, the volatile acid has been calculated as acetic acid, and the non-volatile as tartaric. The reducing sugar has been calculated as glucose, and the presence of this substance has been qualitatively proved in each case by formation of the osazone.

Liquid extract of coca contains a variable proportion of alkaloid, the average being about 0.4 per cent. The quantity of an extract of this strength which corresponds to a dose of the wine has been calculated for the first three wines; in the fourth the identity of the trace of alkaloid found was not sufficiently certain; and in the fifth it was not possible to say how much of the alkaloid was derived from coca and how much from cinchona.

Liquid extract of cinchona (*B.P.*) contains 5 per cent. of alkaloids, not less than half of which consists of quinine and cinchonidine. The quantity of this extract which corresponds to a dose of the wine has been calculated for those wines which contained cinchona alkaloid, except in the case in which quinine was practically absent.

ARNBRECHT'S COCA WINE.

Several varieties of this wine are supplied by Armbrrecht, Nelson, and Co., Duke Street, Grosvenor Square, London, W.; the one taken for analysis is described as Coca Port. The price of a bottle holding 21 fl. oz. is 4s. The dose is one wineglassful before or with each meal.

Analysis showed that 100 parts by measure contained:

Alcohol	...	15.05 parts by measure.
Total solids	...	23.5 parts.
Glucose	...	20.8 "
Ash	...	0.28 "
Acidity, volatile	...	0.08 "
fixed...	...	0.34 "
Alkaloid	...	0.006 "

The alkaloid caused numbing when applied to the tongue and agreed in other properties with the alkaloid of coca. A wineglassful of the wine would represent about 14 minims of liquid extract of coca.

SAVAT'S COCA WINE.

This wine is supplied wholesale at Bartholomew Close, London, and Hanover Street, Liverpool. No maker's name is given on the label. The price is 4s. a bottle holding 10 fl. oz.

Dose: A dessertspoonful in half a wineglass of water or wine before meals; after several days this may be doubled.

Analysis showed that 100 parts by measure contained:

Alcohol	...	23.40 parts by measure.
Glycerine	...	8.1 parts.
Total solids	...	5.4 "
Glucose	...	2.6 "
Ash	...	0.44 "
Acidity, volatile	...	0.13 "
fixed...	...	0.24 "
Alkaloid	...	0.07 "

The alkaloid caused numbing when applied to the tongue, and agreed in other properties with the alkaloid of coca. A dessertspoonful of the wine would represent about 21 minims of liquid extract of coca.

MARIANI'S TONIC COCA WINE (VIN MARIANI).

This wine is supplied by Mariani and Co., Paris, in bottles holding 17½ fl. oz. and costing 4s.

Dose: One claret glass full before or after the principal meal.

Analysis showed that 100 parts by measure contained:

Alcohol	...	16.40 parts by measure.
Total solids	...	8.9 parts.
Glucose	...	2.0 "
Cane sugar	...	4.9 "
Ash	...	0.22 "
Acidity, volatile	...	0.10 "
fixed	...	0.35 "
Alkaloid	...	0.01 "

The alkaloid caused numbing when applied to the tongue and agreed in other properties with the alkaloid of coca. A wineglassful would represent about 24 minims of liquid extract of coca.

HALL'S WINE.

This wine, supplied by Stephen Smith and Co., Ltd., Bow, London, E., is in bottles, price 1s. 9d. and 3s., holding respectively 1½ and 21 fl. oz.

Dose: Adults—wineglassful thrice daily.

This wine appears to be now advertised and sold simply as Hall's wine, and neither on the label nor on the circular enclosed in the package is any reference made to coca, but on the carton are the words "Recommended by the *Lancet*, April 9th, 1892." Reference to this recommendation showed that it dealt with "Hall's Coca Wine," and stated that cocaine could be readily extracted from the wine and identified, and also that "a wineglassful is stated to contain one drachm of the soluble active ingredients of the leaves" of coca. Our results show that the wine now sold is of very different composition.

Analysis showed that 100 parts by measure contained:

Alcohol	...	17.85 parts by measure.
Total solids	...	14.1 parts.
Glucose	...	11.9 "
Ash	...	0.29 "
Acidity, volatile	...	0.10 "
fixed	...	0.34 "
Alkaloid	...	0.003 "

The total quantity of alkaloid extracted from over half a pint of the wine barely sufficed to cause any appreciable numbing when applied to the tongue.

MARZA WINE.

The agents for this wine are Wright, Layman, and Umney, Ltd., Southwark, S.E. It is sold in bottles, holding 24 fl. oz., price 3s. 9d. Dose: A wineglassful three times daily, before or after food.

This is described on the package as "containing iron, phosphorus, coca, and pepsine."

Analysis showed that 100 parts by measure contained

Alcohol	...	17.43 parts by measure.
Total solids	...	9.4 parts.
Glucose	...	7.6 "
Ash	...	0.23 "
Acidity, volatile	...	0.11 "
fixed	...	0.30 "
Alkaloid	...	0.001 "
Iron	...	0.005 "
Phosphorus in combination, calculated as phosphoric acid	...	0.03 "

No free phosphorus could be detected. The alkaloid was bitter, and caused numbing when applied to the tongue. Although so small in quantity, its solution showed the fluorescence characteristic of quinine or quinidine.

No digestive action on egg albumen could be detected in eight hours, after removing the alcohol from the wine at a low temperature.

CHRISTY'S KOLA WINE.

This wine is supplied by Thos. Christy and Co., Old Swan Lane, London, in bottles, price 3s. 6d., holding 12½ fl. oz.

Dose: A liqueur glass, or one ounce, occasionally.

It is stated on the label that each ounce contains the equivalent of 30 grains of kola.

Analysis showed that 100 parts by measure contained:

Alcohol	...	18.85 parts by measure.
Total solids	...	10.9 parts.
Glucose	...	8.6 "
Ash	...	0.25 "
Acidity, volatile	...	0.09 "
fixed	...	0.24 "
Alkaloid	...	0.03 "

The alkaloid showed the characteristic reactions of caffeine, which is the alkaloid of kola. According to published statements, kola nuts contain 2 to 2½ per cent. of caffeine; taking the lower of these figures, 0.03 part of caffeine would represent 1.5 part of kola, or 6½ grains to each fluid ounce of the wine.

VIBRONA.

This preparation is supplied by Fletcher, Fletcher, and Co. Ltd., Holloway, London, N., in bottles holding 20 fl. oz., price 3s. 9d.

Dose: A liqueur glass (about one tablespoonful).

In a circular enclosed with the bottle it is stated:

To the many thousands of invalids who dare not take even the smallest quantity of Cinchona, or its alkaloid—Quinine—on account of the intense and unbearable headache and other distressing symptoms invariably produced, Vibrona has proved an inestimable boon.

Analysis showed that 100 parts by measure contained:

Alcohol	...	19.30 parts by measure.
Total solids	...	16.7 parts.
Glucose	...	6.4 "
Cane sugar	...	5.2 "
Ash	...	0.27 "
Acidity, volatile	...	0.07 "
" fixed	...	0.28 "
Alkaloid	...	0.02 "

The alkaloid was slightly bitter, and its solution showed a very slight fluorescence; it agreed well in its characters and reactions with a mixture of the alkaloids of cinchona, from which the quinine and cinchonidine had been removed.

BUGEAUD'S WINE.

This wine is supplied by Lebeault et Cie, of Paris, in bottles, price 4s., holding 16 fl. oz.

Dose: Adults, a small wineglassful half an hour before meals. This is described on the label as "Nutritive-Tonic Wine of Cinchona bark and Cocoa."

Analysis showed that 100 parts by measure contained:

Alcohol	...	14.80 parts by measure.
Total solids	...	21.5 parts.
Glucose	...	18.9 "
Ash	...	0.40 "
Acidity, volatile	...	0.13 "
" fixed	...	0.33 "
Alkaloid	...	0.01 "

The alkaloid was bitter, and agreed in its properties with the alkaloid of cinchona.

A wineglassful would represent about 2 minims of liquid extract of cinchona.

QUINA LAROCHE.

The London agents of this preparation are Comar and Son, Holborn Viaduct, London. The price is 2s. 9d. a bottle, holding 9 fl. oz.

Dose: As a stomachic, two measures per day after meals; for fevers, four to six measures a day. The measure supplied with the bottle holds a little over 1 fl. oz.

The preparation is described as

a vinous extract, containing concentrated in a small volume and free from all alteration all the soluble principles of the three best kinds of cinchona: red, yellow, and grey.

Analysis showed that 100 parts by measure contained:

Alcohol	...	15.90 parts by measure.
Total solids	...	26.9 parts.
Glucose	...	22.2 "
Ash	...	0.20 "
Acidity, volatile	...	0.05 "
" fixed	...	0.16 "
Alkaloid	...	0.05 "

The alkaloid was bitter, and agreed in its properties with the alkaloid of cinchona.

"Two measures" would represent about 10 to 15 minims of liquid extract of cinchona.

SERRAVALLO'S TONIC BARK AND IRON WINE.

This wine, stated to be prepared by J. Serravallo, Trieste, Austria, is sold in this country at the price of 3s. 6d. a bottle, holding 18 fl. oz.

Dose: Two or three liqueur glasses a day.

Analysis showed that 100 parts by measure contained:

Alcohol	...	17.23 parts by measure.
Total solids	...	21.2 parts.
Glucose	...	6.8 "
Cane sugar	...	12.2 "
Ash	...	0.23 "
Acidity, volatile	...	0.05 "
" fixed	...	0.23 "
Iron	...	0.01 "
Alkaloid	...	0.05 "

The alkaloid was bitter, and agreed in its properties with the alkaloid of cinchona.

A liqueur glassful would represent about 3 minims of liquid extract of cinchona.

ST. RAPHAEL QUINQUINA TONIC WINE.

This wine, supplied by the Société du St. Raphael-Quinquina of Paris, is sold in this country at 3s. 3d. a bottle, holding 25 fl. oz.

Dose: A glass before and during meals.

Analysis showed that 100 parts by measure contained:

Alcohol	...	16.89 parts by volume.
Total solids	...	14.3 parts.
Glucose	...	11.8 "
Ash	...	0.25 "
Acidity, volatile	...	0.13 "
" fixed	...	0.19 "
Alkaloid	...	0.038 "

The alkaloid was moderately bitter, and agreed fairly in its properties with the alkaloid of cinchona.

A wineglassful would represent about 1½ minims of liquid extract of cinchona.

VANA.

This preparation is supplied by Burroughs, Wellcome, and Co., London, E.C., a bottle holding 17½ fl. oz. costing 2s. 6d.

Dose: Half a wineglassful three to four times daily.

This is described on the label as "presenting calcium glycerophosphate and the alkaloids of cinchona bark in a pure, sound wine."

Analysis showed that 100 parts by measure contained:

Alcohol	...	19.20 parts by measure.
Total solids	...	23.9 parts.
Glucose	...	20.0 "
Ash	...	0.23 "
Acidity, volatile	...	0.05 "
" fixed	...	0.27 "
Alkaloid	...	0.03 "
Calcium	...	0.01 "
Phosphorus in combination, calculated as phosphoric acid	...	0.13 "

The alkaloid was bitter, and agreed in its properties with the alkaloid of cinchona. The total calcium found is equivalent to 0.05 per cent. of calcium glycerophosphate; the phosphoric acid, however, is sufficient for more than five times this amount.

Half a wineglassful would represent about 3 minims of liquid extract of cinchona.

NOURRY'S IODINATED WINE.

This medicated wine is supplied by F. Comar and Son, Holborn Viaduct, London, at 3s. 6d. a bottle, holding 10½ fl. oz.

Dose: For adults, one tablespoonful.

In a pamphlet enclosed with the bottle it is stated that

Nourry's Wine is an iodinated wine rich in iodine... the iodine is chemically combined with tannin to an almost tasteless compound, and this is dissolved in a sound sweet wine.

The quantity of iodine is given as 1½ grains in each fluid ounce.

Analysis showed that 100 parts by measure contained:

Alcohol	...	11.5 parts by measure.
Total solids	...	27.3 parts.
Glucose	...	21.4 "
Glycerin	...	6.6 "
Ash	...	0.35 "
Acidity, volatile	...	0.06 "
" fixed	...	0.39 "
Iodine	...	0.33 "

This amount of iodine is practically equivalent to 1½ grains per fluid ounce; its reactions indicated that it was in combination with tannin.

BAUDON'S WINE.

The wine, supplied by the Maison Baudon, Paris, is sold in this country through W. A. Massingham, London, E.C. The price charged for a bottle holding 13½ fl. oz. is 3s. 6d.

Dose: For adults—a wineglassful pure, or diluted with water or seltzer water before or during each principal meal. This is described on the label, which is in French, as "antimonio phosphate," but in a circular in English enclosed with the bottle, it is said to be "a very agreeable preparation of the Phosphates, with a basis of Pure Muscat Wine," and no mention is made of antimony.

Analysis showed that 100 parts by measure contained:

Alcohol	...	12.75 parts by measure.
Total solids	...	14.5 parts.
Glucose	...	13.1 "
Ash	...	0.56 "
Acidity, volatile	...	0.12 "
" fixed	...	0.67 "
Phosphate, calculated as phosphoric acid	...	0.54 "
Antimony	...	a minute trace.

DUSART'S WINE.

This wine, to be obtained wholesale from Wilcox and Co., London, W.C., is sold at the price of 4s. a bottle, holding nearly 14 fl. oz.

Dose: From 2 to 3 Bordeaux glasses for adults. This is described on the label as a "lacto-phosphate de chaux, ferrugineux"; it appears that a non-ferruginous variety is also prepared.

Analysis showed that 100 parts by measure contained:

Alcohol	...	16.85 parts by measure.
Total solids	...	15.4 parts.
Glucose	...	12.8 "
Ash	...	0.55 "
Acidity, volatile	...	0.11 "
" fixed	...	0.35 "
Iron	...	0.09 "
Calcium	...	0.07 "
Phosphorus in combination, calculated as phosphoric acid	...	0.03 "

ST. RAPHAEL TANNIN WINE.

This wine is supplied in this country by a company in Valence (Drôme), France, through English agents (E. Gallais and Co.) in London.

The price of a bottle, holding 16½ fl. oz., is 2s. 6d.

Dose: Half a wineglassful after meals.

A pamphlet enclosed with the wine contains a dissertation on its properties, etc.; no definite statement is made as to the kind of tannin which it contains, and it is not apparent whether it is or is not intended to imply that it is derived from cinchona.

Analysis showed that 100 parts by measure contained:

Alcohol	...	14.65 parts by measure.
Total solids	...	16.5 parts.
Glucose	...	14.0 "
Ash	...	0.29 "
Acidity, volatile	...	0.11 "
" fixed	...	0.41 "

Indications were obtained of a minute trace of alkaloid. The amount of tannin present did not differ greatly from the amount in an ordinary port wine, matured in wood, with which it was compared.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

The annual general meeting of this Society was held at 11, Chandos Street, Cavendish Square, on May 20th. In the absence of the President, Mr. J. Warrington Haward, acting Treasurer, took the chair. Twenty members were present.

It was reported that the society's invested funds amount to £100,071, from which was derived in interest the sum of £3,121 17s. 1d.; the sum received in subscriptions and donations was £645. During the past year the sum of £3,017 was distributed amongst the annuitants of the charity, 48 widows and 16 orphans, each widow receiving on an average £50 besides an additional £10 as a Christmas gift, and each orphan £12 and a gift of £5 at Christmas. The Copeland Fund is a special fund which

enables the society to grant to any widow or orphan already in receipt of the society's ordinary relief extraordinary assistance in special circumstances of unusual distress, such as blindness, paralysis, insanity, severe disabling accident, or grave permanent disease, and to continue such extra relief in the case of orphans beyond the age of 16 or 18 years (at which under the society's existing by-laws the ordinary relief ceases) for such further period as the court of directors may think fit. During the year two widows in receipt of grants died. One, whose husband had paid in subscriptions £19 19s., received £1,500. The other, whose husband had paid in annual subscriptions £31 10s., received £3,300; she had been in receipt of grants since 1855. Two new widows were elected during the year, and on December 31st there were 47 widows and 15 orphans in receipt of grants. One of the widows has been on the books since 1854, and has already received over £2,200. Relief is only granted to the widows and orphans of deceased members who have paid their annual subscription for three years, or who are life members. During the year nearly fifty letters were received from widows of medical men, who, in many instances, had been left practically penniless, asking for relief, but this had to be refused, as their husbands had not been members of the society. The directors cannot too strongly urge upon the members of the medical profession, especially the younger, the desirability of joining the society. Membership is open to any registered practitioner who at the time of his election is resident within a twenty-mile radius from Charing Cross. Should any member remove beyond the limits of the society he nevertheless continues to be a member. The annual subscription is two guineas; every member who has paid this sum for twenty-five years becomes a member for life. Life membership may also be obtained by the payment of one sum, varying with the age of the applicant. Further particulars and application forms may be obtained from the Secretary at the offices of the Society, 11, Chandos Street, Cavendish Square, W.

A cordial vote of thanks was passed from the chair to the editors of the medical papers in which from time to time notices of the society are published.

BRITISH MEDICAL BENEVOLENT FUND.

At the May meeting of the Committee sixteen cases were considered and grants amounting to £150 made to fourteen applicants, two cases being postponed for further inquiry. Appended is an abstract of the cases relieved:

Daughter, aged 63, of late M.R.C.S. Was left quite unprovided for at father's death more than thirty years ago, and now, with poor health and failing eyesight, finds it impossible to support herself. Relieved twice, £24. Voted £12.

Wife, aged 48, of L.R.C.P. Edin. For several years past has been obliged to support herself on account of husband's whereabouts being unknown. Now asks for a little help towards the education of one of her daughters, aged 10. Voted £6.

L.F.P.S. Glasg., aged 75. Has practised for many years past in the South-West of England, but receipts have now dwindled to less than £1 a week. No children. Voted £12.

Widow, aged 57, of M.D. Dubl. Quite unprovided for at husband's death six months ago, and is at present incapable of earning a living owing to ill-health. One child, aged 12. Voted £10.

Daughter, aged 66, of late M.R.C.S., L.S.A. Has supported herself since the age of 17, and helped younger members of the family, but is now obliged to give up a small school on account of ill-health. Slight help from a brother, who can ill afford it. Voted £12.

Widow, aged 57, of L.R.C.P., L.R.C.S. Irel. Finds great difficulty in getting a suitable post, and is temporarily given a home by a widowed sister, who is herself partly dependent on her daughters. Relieved once, £5. Voted £5.

L.R.C.P., L.R.C.S. Edin., aged 49, who practised for several years as an assistant, but had to have one eye enucleated, and has nearly lost the sight in the other, owing to iritis and glaucoma. No income; wife left lodgings. Five children, aged 14 to 9. Relieved once, £18. Voted £18.

Widow, aged 56, of M.R.C.S. Eng., L.R.C.P. Edin. Since husband's death, more than twenty-five years ago, has maintained herself by cleaning offices, but now suffers from bronchitis and emphysema, and is unable to continue such hard work. Relieved twice, £22. Voted £12.

Widow, aged 62, of L.R.C.P., L.R.C.S. Edin. Only income a small pension from a City company and has recently had many unavoidable expenses in consequence of a serious illness. Two sons only just self-supporting. Relieved twice, £12. Voted £10.

Widow, aged 48, of M.B., C.M. Edin. Practically unprovided for at husband's death twelve years ago, but with the help of

It may be pointed out that the lubricant application here recommended corresponds closely with the diachylon simplex which appears under the head of "Emplasters"

in John Quincy's *Pharmacopœia Officinalis et Extemporanea*, or a Complete English Dispensatory (Second Edition, London, MDCCXIX). The following is his formula: Take mullage of marsh mallow, roses, or Foenugreek (fennel) and linseed, ana lb. ij; old oil, lb. ij; litharge, lb. jss. Boil to a consistence.

Although the French are rather boastful of their freedom from what they regard as superstitions, they are much given to the worship of relics—provided they have no association with religion. Gambetta, it appears, had his right eye enucleated by de Wecker, and had to get a glass eye in its place. A French journal has recently—we cannot help thinking, somewhat unkindly—published a letter from the great Tribune of the people to his father, in which he tells him of the operation, dwelling on the loss of time caused thereby, the cost of the artificial eye, the increased cost of living owing to the Paris Exposition and a present he will have to give the surgeon, who refused a fee. Whether this eloquent appeal had the effect on the old tradesman of Cahors which it seems to have been intended to produce is not stated. We are told, however, by another journal that a pupil of de Wecker, who assisted at the operation, took possession of the eye and sealed it up in a bottle. When Gambetta had become famous, the pupil, who had in the meantime gained fame as an ophthalmologist, one day showed the eye to an American millionaire, who bought it for a great price. Americans, we know, are always on the watch to capture European works of art; but if they also buy up the damaged works of Nature, some of our museums might do a brisk trade.

Last year there was published in the *Nederlandsch Tijdschrift voor Geneeskunde* an account contained in a pamphlet in the library of the University of Leyden of an operation for the separation of xiphopagous twins which was successfully performed at Basel in 1689. Dr. Curt Schelenz of Brunswick, writing in the *Deutsche medizinische Wochenschrift* not long ago, pointed out that among the reports of the Imperial Leopold Academy (years 8 and 9) there are two accounts of the event—a summary of the Leyden pamphlet by Dr. Emanuel Koenig and a fuller account by the operator himself, Dr. Fatus. It was published by Theodor Zwinger, who was professor at Basel from 1653 till 1724. It is there stated that the twins were born at Hittingen, and notwithstanding the unfavourable position in which one of them lay—*recurvato capite et reliquo corpore*—the delivery took only two hours. The next day the twins, which were girls, were taken by Dr. Samuel Brunn to Fatus at Basel. Fatus consulted all the leading professors at Basel, who gave it as their opinion that although the issue was very doubtful, an operation should be attempted. The unifying band extended from the ensiform cartilage to the navel, and was of considerable thickness. The cartilaginous portion was cut through with a knife; the sister parts were divided by means of a strong string. The chief magistrates and officials of the city were invited to witness the operation. The wound healed in ten days. The children made a good recovery. The pamphlet contains illustrations which were reproduced in the Reports of the Emperor Leopold Academy.

Medical News.

The University of Leipzig will celebrate its five-hundredth anniversary at the end of July.

DR. D. EDGAR FLINN, Medical Inspector, Local Government Board, Ireland, and Dr. W. J. Howarth, M.O.H. Kent, have been elected Fellows of the Royal Sanitary Institute.

GEORGES DREYER, M.A. Oxon., M.D. Copenhagen, Professor of Pathology in the University of Oxford, has been elected a member of the Danish Royal Academy of Letters and Science.

A MEETING of the Socialist Medical League will be held at the Holborn Restaurant on Thursday next, when Dr. J. Jenkins Ross of Bourneville will open a discussion on the nationalization of the medical profession; the chair will be taken by Dr. Satter, L.C.C., at 4 p.m.

The annual Welsh medical dinner will be held at the Criterion Restaurant, London, on Tuesday, June 15th, when the chair will be taken by Dr. D. C. Lloyd Owen, of Birmingham, at 7.30 p.m. The date has been chosen in connexion with the National Eisteddfod in London, and will not clash with any of its celebrations.

The tuberculosis exhibition at the Art Gallery, White-chapel, arranged by the National Association for the Prevention of Consumption and other forms of Tuberculosis will be opened on Wednesday next, at 3 p.m., by the President of the Local Government Board; discussions will be held on June 8th, 9th, and 10th. The exhibition will remain open until June 19th, and popular lectures will be delivered on eight evenings.

The sixth meeting of the French National Periodical Congress of Gynaecology, Obstetrics, and Paediatrics will be held at Toulouse in September, 1910. The following questions are proposed for discussion: Acute curable forms of pulmonary tuberculosis in children; eczema of nurslings; vertebral osteomyelitis; pyloric stenosis in sucklings; megacolon; solid tumours of the ovary; biliary lithiasis complicating pregnancy and parturition; pathology and treatment of obstinate vomiting of pregnancy.

At the last meeting of the International Physiological Congress, which was held at Heidelberg in 1907, it was decided to hold the next Congress at Vienna in 1910 at Whitsuntide. It has been found, however, that at this time of year it would be impossible for a large number of physiologists to attend the congress, and the local committee of the congress at Vienna has therefore, after consulting the local secretaries in the various countries, determined to change the date of the congress. In accordance with the general wish, it will be held from September 25th to 30th, 1910.

A COMMITTEE has been formed to collect funds to provide for a suitable memorial to the late Dr. J. J. Ridge of Enfield, honorary secretary of the British Medical Temperance Association since 1874 until his death. It is proposed to erect in some public place in Enfield a memorial in granite and to found a Ridge Convalescent Fund for the benefit of patients at the Enfield Cottage Hospital, of which Dr. Ridge was the originator. Donations may be sent to the Enfield Branch of Lloyd's Bank, Enfield Town, to the credit of the account of the Ridge Memorial Fund, or to the Honorary Treasurer, Dr. Howard Distin, Holtwhite House, Enfield. A sum of between £70 and £80 has already been received.

MR. C. B. LOCKWOOD occupied the chair at a special meeting of the Motor Union Committee of Medical Motorists held at the offices of the union to consider the Budget proposals of the Chancellor of the Exchequer in so far as they affect members of the medical profession using motor cars. There was a representative attendance, members having travelled from the North and West of England in order to be present. The committee resolved that the motor car has now become an absolute necessity to a medical practitioner, who is, therefore, entitled to make a special claim for abatement. It was resolved to approach the Chancellor of the Exchequer with a view to securing a rebate of 1½d. a gallon on petrol used by medical men. A letter was read from Mr. W. Joynton Hick, M.P. (Chairman of the Motor Union), stating that the Chancellor had agreed to receive a deputation on the matter.

The ninth annual dinner of the Medical Graduates' College and Polyclinic was held on May 24th at the Trocadero Restaurant, Piccadilly. Professor Howard Marsh, who was in the chair, in proposing the toast of the Polyclinic, emphasized the importance of post-graduate teaching, and observed that it was impossible for a doctor to learn his work once and for all. He considered that the public should contribute to the funds of the Medical Graduates' College and Polyclinic. Sir Jonathan Hutchinson, in replying, described in detail the merits of the consultation methods followed at the Polyclinic, and the success with which the plan answered, especially in regard to obscure and difficult cases. Dr. Theodore Williams also replied. Dr. C. O. Hawthorne, in proposing a toast to Captain A. E. Howard Pinch, I.M.S., referred to the administrative difficulties in connexion with the Polyclinic from an academic as well as from a domestic point of view. He eulogized the achievements of Captain Pinch during his tenure of office as Medical Superintendent of the Polyclinic, and concluded by reading the words of a testimonial to Captain Pinch, and presented it to him with a cheque for one hundred guineas. Captain Pinch said that during his ten years' work at the Polyclinic he had done his best, and regretted much leaving. The toast of "The Guests" was submitted by Dr. Danlas Grant in a humorous speech, during which he averred that the Polyclinic was not a "close borough," but a valuable agent for the spread of post-graduate teaching. Sir William Church, who replied, said that the Polyclinic filled a wide gap. Sir Donald MacAlister proposed the toast of "The Chairman," who suitably replied.

British Medical Journal.

SATURDAY, MAY 29TH, 1909.

THE ANNUAL REPRESENTATIVE MEETING.

THE business to come before the Annual Representative Meeting to be held at Belfast on Friday, July 23rd, and the following days is now so far arranged that it was found possible in the SUPPLEMENT for last week to publish the provisional agenda. The document included the annual report of the Council, and that report will, so far as at present known, constitute the greater part of the agenda, for under the articles of association the only additional matters which can now be inserted on the agenda are supplementary reports by the Council, or further reports by committees instructed to report to the meeting, and motions relevant as amendments or riders to any motion already recorded.

It will be seen that the agenda list this year differs in form from the document published at corresponding dates in previous years; this is attributable to certain changes in the by-laws of the Association and standing orders of the Representative Meeting, whereby all standing committees now report through the Central Council and not, as formerly, in some instances direct to the Meeting. Certain other alterations are due to changes in the rules of the Meeting as to the procedure to be followed on the presentation of reports; it is hoped that these changes, made by the Annual Representative Meeting last year with the object of expediting business without sacrifice of thoroughness, will be found to work satisfactorily.

The Representative Meeting is not only called upon to deal with the internal affairs of the Association itself, but also with a very large volume of important business affecting the interests of the profession in its relations to the State and to the public. It will be found on comparing the agenda for this year with that for last year that there is a diminution in the amount of purely internal business, the chief reason being that last year the meeting had to consider in detail all the clauses of the draft Charter as well as the findings and recommendations of the Special Finance Inquiry Committee. The matters of general professional interest set down for discussion are numerous and important. As an instance of a matter in which the Association has taken action as the body representing the interests of the profession at large, we may take the report prepared by the Medico-Political Committee on the medical inspection of school children and the treatment of those found defective. This report was based on the replies of 102 Divisions to a document circulated in December last. The report, as will have been recognized by those who studied it in the SUPPLEMENT for May 15th, is a very well considered and comprehensive document which reviews the new problems presented to the profession by the institution of compulsory medical inspection, and makes a series of recommendations on which the Divisions are now invited to express an opinion and to instruct their Representatives. The action already taken with

regard to the terms of appointment and remuneration of school medical officers has had a very beneficial influence upon public opinion, and we may note in passing the fairness of the recommendation that a person appointed with the title of Assistant Medical Officer of Health to do medical inspection should be the officer not merely of the local Education Committee but also of the Sanitary Committee, and that his duties should include work which would enable him in future to base a claim for an appointment elsewhere as medical officer of health upon the experience gained in the subordinate office.

Although these matters will require continued vigilance, the recommendations possessing the most immediate interest and novelty are those with regard to the treatment of school children found on medical inspection to be defective. The report advises that the reference of such children to public medical charities should be opposed, and that their reference to the Poor Law should likewise be opposed pending such reforms as may result from the consideration of the reports of the Royal Commission. The mode of treating such children which is recommended is that they should be placed under the care of private practitioners, who, if the parents cannot themselves afford to pay, should be adequately remunerated out of public funds without the intervention of the Poor Law. To carry this out it is advised that in towns the work should be done by private practitioners at school clinics established in schools or independent buildings, and that in sparsely populated districts the surgeries of private practitioners should be recognized as places at which treatment may be obtained, under proper safeguards against abuse, at the public expense.

As not remotely bearing upon this subject, attention may be drawn to paragraph 58 of the Report of Council this states that after long consideration and repeated revision by the legal advisers the model rules for a public medical service are now ready to be issued for the consideration of the Divisions, and it will be seen that the Wandsworth Division has given notice of a rider instructing the Council to formulate resolutions embracing the main principles affecting medical contract practice, while the St. Pancras and Islington Division has another rider expressing the opinion that the time is opportune for the Association to draft a scheme for a public medical service to embrace philanthropic dispensaries and medical services, school clinics, the Poor Law medical service, provident dispensaries, and the medical services of friendly societies and clubs. It will be recollected that both the majority and minority of the Royal Commission, in discussing the reform of the present system of Poor Law medical relief, made recommendations which would lead, in fact if not in name, to the establishment of a public medical service. The main difference between the two parties on the Commission was that the majority favoured the system under which the work should be distributed among all registered medical practitioners in the district willing to undertake it, while the minority recommended the creation of a special service of whole-time officers under the control of a principal medical officer in each district. The subject cannot be satisfactorily considered apart from improvements which are generally admitted to be desirable in the public health service, and it will be seen that a step in the right direction has been taken in the Housing and Town Planning Bill now referred to a Grand Committee of the House of Commons. Owing to representations

made by the Association, acting along with the Society of Medical Officers of Health, a provision was introduced last year, giving security of tenure to medical officers of county councils, and this has been retained. The bill, however, contains no provisions giving similar security to district medical officers, though their duties and responsibilities are to be increased by the bill, and steps will be taken to bring the matter under the notice of the House of Commons this year.

The Hospitals Committee, dealing as it does with complicated questions affecting the material, educational, and scientific interests of the profession, must needs proceed with considerable deliberation, but it will be seen that it submits a final recommendation as to the need for requiring a medical certificate of suitability for hospital treatment as a condition of such treatment, except in cases of casualties, and also a definition of a nursing home, which, if adopted, will help to clear up some perplexities. This section of the report will raise the questions whether the Representative Meeting would not do well to express the opinion that no fresh public medical institution should be opened without previous consultation with the local profession, and that on all bodies receiving public subscriptions formed to promote or control medical assistance, including hospitals, there should be adequate direct representation of the local medical profession. A memorandum upon this second point has recently been circulated to the Divisions (SUPPLEMENT, April 10th, p. 161).

The recommendations arising out of the work of the Science Committee are evidence that that body has in recent years considerably extended the scope of its activity, and the Association is asked, while not relaxing its efforts to encourage scientific research by way of scholarships and grants, to take or to consider the advisability of taking certain steps for encouraging and organizing the scientific work of Divisions and Branches and the literary labours of individual members. For the latter purpose it is proposed that a special character should be given to the central library of the Association by its conversion, as far as possible, into a lending library available to provincial members, and that, as a first step, a collection and list of monographs and periodicals should be formed, which may be lent under approved conditions. It may not be inappropriate to point out that this proposal follows a division natural to any collection of medical books. There are, on the one hand, standard works or textbooks of medicine and surgery, which a member may require to consult with relative frequency upon particular points; and, on the other, monographs, often expensive to purchase, and periodicals of which it is not always easy to form a complete set; such monographs and periodicals, are perhaps only consulted by individual members at long intervals, generally when engaged in the preparation of some paper. We apprehend, judging from the later sentences of the paragraphs on the library, that the intention is to encourage the formation of local libraries containing standard works available for immediate consultation, and a central lending collection for the benefit of members when prosecuting some particular line of inquiry or investigation. On this point it would appear that an immediate decision is asked; but the next paragraph (No. 80, p. 296), dealing with scientific work of Divisions and Branches, raises points which are thought still to require further consideration in order that a good working scheme may be evolved.

There are many other subjects of importance in the agenda paper which ought to be studied, not only by the Representatives, but also by every member who takes a lively interest in the work of the Association, for it can only be through general co-operation of all its members that the Association can attain the full development of its powers of usefulness.

UNIVERSITY REFORM.

It is not only the University of London that feels the necessity for reform to meet the new conditions brought about by the remarkable movement in England for the organization of university education on broader lines—broader not only in relation to the public to which the appeal is made, but also in relation to the expansion of science and the application of the newer methods to the old learning. Both at Oxford and at Cambridge reform is in the air, and both the older universities hope to avoid the ordeal of a Royal Commission, to which it is deemed essential the University of London should once more be submitted. Lord Curzon's letter has for the moment concentrated attention on Oxford, but in Cambridge proposals are on foot having a similar end, and perhaps, from the way in which opinion has been conciliated, are more likely immediately to be carried out. The public interest in the matter would perhaps be greater were it not that the constitution and local government of both the older universities are so mysterious that they are little understood even by the graduates themselves, for during his career at Oxford or Cambridge the undergraduate is hardly ever brought into touch with the university itself, and never with its governing authorities; university control, as far as he is concerned, is almost entirely limited to the activities of the proctors. At both universities, however, grave difficulties have stood in the way of carrying out reforms rendered necessary by the altering conditions of modern education. The control of the university syllabus has lain in the hands not of the teachers in the university, but of bodies curiously and even grotesquely constituted, and in consequence true education has suffered. The machinery to be set in motion to bring about the simplest reform has been cumbrous, and time that might be spent in the direct or indirect furtherance of original work, or in increasing the efficiency of university or college teaching, has had to be squandered on university politics.

The essential feature of the proposals made both at Oxford and Cambridge is the reform of the university organization, the object of the reformers being to simplify the machinery, to give greater influence to resident expert opinion, and to make the final body of appeal, the whole body of M.A.'s, more truly representative than at present of general graduate opinion.

In the two universities the subject has been approached from widely differing standpoints. At Cambridge informal committees have collected those points on which all parties are at one in the university in desiring reform, chiefly constitutional points, and have urged the Senate to consider them with a view to their adoption at the earliest possible date. It is proposed that the governance of the university should be confided to two bodies: (1) a Congregation consisting of residents which would deal with all kinds of business save that involving the widest and most important questions of

policy and certain formal matters, and (2) a Senate consisting of all M.A.'s. There would be a right of appeal from Congregation to the Senate, and a subsidiary scheme has been put forward with the aim of encouraging a graduate to proceed to the degree of M.A., and to keep his name on the books of his college or of the university, instead of, as at present, in many instances completely severing his connexion. It is also proposed, and apparently generally agreed, that the system of co-operation in teaching between colleges should be extended and systematized. When the constitution has been reformed, and power to act placed in the hands of those familiar with academic needs, other reforms in all probability similar to those suggested at Oxford may be expected to follow.

At Oxford a more comprehensive scheme has been outlined by the Chancellor, who, not being bound to present a plan of reform on which all parties would be agreed, has been able to formulate proposals of a definite character with something approaching an air of finality, and has induced the Hebdomadal Council to accept the main principles laid down. Besides suggesting the reform of the university constitution on lines similar to those recommended at Cambridge, he has induced the council to accept the principle that Greek shall cease to be a compulsory subject. By the acceptance of the principle that no one should be allowed to come into residence without having passed an entrance examination or its equivalent, a blow has been aimed at the mere idler, for in this respect the rules of the University of Oxford present a curious contrast to those of London, and have preserved beyond its day of usefulness the original conception of a university as an assembly of willing students. The suggestions relating to scholarships and fellowships should provide funds for the encouragement of original research, and for giving pecuniary assistance more exclusively to those who are seriously in need; the plans for co-ordinating college lectures should economize the teaching energies of the lecture staff and in this way contribute to the general efficiency, while the encouragement of the relatively poor man should enable many more medical students than at present to secure the advantages of an Oxford training.

The chorus of praise with which Lord Curzon's letter has been received at Oxford is remarkable evidence of his tact, and the time spent in collating different views has not been wasted, for it seems probable that the majority of his suggestions will be accepted. On two of his points, however, the council is dumb: the encouragement of the working classes to enter the colleges, and the granting of degrees to women.

The effect on medical education of the proposals now under discussion at Oxford and Cambridge is necessarily at present uncertain, but it is to be expected that the medical course will benefit with other subjects by the establishment of a standard and a system generally more in keeping with modern conditions. The omission of Greek from the obligatory Oxford syllabus will render the university more easy of access to those who have had a specialized scientific training; the universities will be able to adapt themselves more rapidly than has been the case hitherto to the changing conditions of material requirements, and, above all, something will have been done to render them less prohibitively costly to the sons of professional men. From the more general standpoint the willingness of the universities to under-

take the work of reform from within is an encouraging sign, and may well stimulate the medical schools of London to put a practical working scheme before the Royal Commission.

DIRECT REPRESENTATION.

By a somewhat narrow majority of the members present the General Medical Council voted on Tuesday last that representations should be made to the Privy Council to the effect that it is expedient to confer on the registered practitioners resident in England and Wales the power of returning an additional member to the General Council. Only a small number of the members of the Council voted against the resolution, the narrowness of the requisite majority being due to the fact that, to render a vote valid, there must be votes recorded by an actual majority of the members present; the abstention of members from voting may thus, in effect, be equivalent to an adverse vote, although its moral significance, if such a term be applicable, is quite different from the record of an adverse vote. It may therefore be worth while to discuss, so far as they may be gathered from spoken words or otherwise inferred, the reasons which led a considerable number to abstain from recording their vote. It may be assumed that the members who adopted this course were not convinced that the addition was quite desirable, though at the same time they were not prepared actively to oppose it.

As Mr. Morris observed, the speeches made in support of the motion themselves afforded some grounds for doubt, apart from what might be styled sentimental considerations. Dr. McManus pointed out that in voting power the direct representatives were, as he put it, too few, even with the proposed addition, "to do any harm," and Dr. Latimer drew attention to the unquestionable fact that, as the voting is not territorial, the candidates must often be very little known to the majority of the electors, who, therefore, vote in the dark, unless the candidate happens to be a person of very wide reputation; this may account for the fact alluded to by Mr. Morris, who himself voted for the resolution, that only 47 per cent. of the constituency troubled to record a vote at all.

There is no doubt that this is a real blot upon the present system of election; the north country general practitioner cannot be expected to have much enthusiasm for the return of a resident in Devonshire or Kent whom he knows only as a candidate adopted by some such body as our Association, and vice versa. The Act, however, is very explicit as to the manner of conduct of the election, and no subdivision of the constituency is possible without amending legislation, though few will be found to doubt that this would be a real reform, and no doubt, if subdivision were feasible, Wales would constitute one of the divisions. The President, in his address, drew attention to the increase in the Council, due to the fact that the establishment of new universities added almost automatically to its members. The expense of the meetings is thus increased, and on the past year's working there is a considerable deficit arising from causes beyond the Council's control. The point was emphasized by a motion brought forward by the Treasurers that the addition, if approved by the Privy Council, should not take effect till the next

general election of direct representatives, as the poll inevitably entailed a heavy expense; this was readily agreed to by Dr. Langley Browne, the mover of the original motion, of whom it may be said that the exceedingly temperate speech in which he brought the matter forward was eminently calculated to win support from those who were wavering.

But though the constitution of the Council will not be materially altered if the Privy Council carries the proposal into effect the general result of the debate and division must be considered satisfactory, inasmuch as the vote is a freer recognition by the Council of the principle of direct representation than has been accorded when similar motions have come up on previous occasions, and such opposition—or rather lack of active support—as the proposal encountered was on grounds quite other than that of general principle.

THE INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

"CHEMISTRY, whether industrial or scientific, is one." Sir William Ramsay contended at the inaugural meeting of the Seventh International Congress of Applied Chemistry, held in the Royal Albert Hall on May 27th. His Royal Highness the Prince of Wales, realizing the importance to this country of every attempt made to bring scientific chemistry into touch with technical chemistry, was in the chair, and the members of the assembled Congress endorsed Sir William Ramsay's contention. "Chemistry," he continued, "is above all a practical science, although in recent years it has tended to become more and more a branch of applied mathematics. The principles remain the same, and indeed the methods are only slightly varied whether the apparatus used are beakers, test tubes, funnels and flasks, or tanks, filter presses, and autoclaves. . . . This, I think, has hardly been realized in a practical manner on this side of the Channel, or, indeed, on the other side of the Atlantic. But our Continental friends have long seen and acted on the conviction that the industrial prosperity of a country can best be advanced by a close friendship and constant association between the technical and the practical workers, between the university and the factory, between the pure and the allied science. Congresses like the present can teach us much; if we learn this lesson from them we shall have gained a valuable national asset."

During the week for which the Congress sits several matters closely affecting medical men are to be discussed. Standardization comes up in section after section, including the standardization of methods of food analysis as applied to different classes of foods. Natural and artificial methods for the purification of water are to be discussed; the bad effects of vitiated air will be considered; the question of dangers due to seaweed accumulation is coming before the Section of Hygiene; and a host of papers are to be read on the various aspects of the milk question. The demonstration at University College by Messrs. A. Harden and W. J. Young of alcoholic fermentation without the intermediation of living cells is especially welcomed because of the difficulties most observers have experienced in reproducing the phenomenon. Several points of pharmacological and physiological interest are to be demonstrated, and the administration of anaesthetics is again to be discussed.

The advantages derived from a congress such as this are dependent only partly on the work actually done at the sectional meetings; they issue nearly equally from the publication of the broad ideas underlying the calling together of such congresses. For the medical profession especially the present Congress is suggestive. From certain aspects the medical man must be classed as the technical expert, and from others as the pure man of science. To the physiologist and the exponents of the so-called pure medical sciences he stands in the former relation, and to the other professions and to the public in the latter. In both the measure of his usefulness to society is largely dependent on the extent of his co-operation with allied workers. Much in the direction of co-operation has already been done—as evidence may be quoted the Sleeping Sickness Bureau, the Royal Society Committee on Anaesthetics, the expeditions sent out to the tropics and elsewhere to investigate the causation of obscure diseases, and many other like undertakings; but very much remains to be done, especially with regard to the relation of medical men to allied trades and professions. Principles such as the compulsory medical inspection of foods require further extension. It is only within the last few months that an organization has been started to bring about co-operation between the architect, the illuminating engineer, and the medical man, and the lack of such co-ordination in the past has notoriously meant unnecessary damage to eyesight and inefficient workmanship in our factories. More co-operation is needed between medical men and schoolmasters, between medical men and municipal authorities, and so on in the various spheres of modern life. It is largely because of the apt application of the ideals of the Congress now being held at South Kensington have to the medical profession that medical men have been called upon to interest themselves in the matter. It should be borne in mind by all who attend its meetings that the influence of the Congress will not be restricted to scientific and industrial chemistry, but will be felt by all the various arts and professions throughout the country.

DR. PAVY.

We desire to offer our warmest congratulations, and we are sure that in so doing we give expression to the feelings of the whole profession, to Dr. Pavy on attaining his 80th birthday this week. He was born in Wiltshire on May 29th, 1829, graduated M.B. in the University of London with honours in all subjects and a gold medal in medicine in 1852, and M.D. in 1853; he was elected Assistant Physician to Guy's Hospital in 1858, and became a Fellow of the Royal College of Physicians of London in 1860, and a Fellow of the Royal Society in 1863. Dr. Pavy's career is one which reflects honour on himself, his profession, and his country; he attained distinction as a physiologist and scientific physician at an early age, but he has never been content to rest upon his laurels, and has continued to work, both by observation and experimental research, at the subject of metabolism, with special reference to diabetes, his last volume on the subject having been published so lately as this spring. This is not the time to attempt to review his life's work, and, indeed, we may hope that it is by no means complete; it is rather an occasion for expressing those sentiments of esteem and affection with which he has inspired his fellow workers and pupils. They will be glad to know that

Mr. Thomas R. Way of 6 and 7, Gough Square, Fleet Street, E.C., has just issued a facsimile of the portrait of Dr. Pavy from the original drawing made by Mr. W. Strang, A.R.A., last year. This very characteristic work hangs in the rooms of the Royal Society of Medicine. It represents Dr. Pavy in his habit as he lives, and the reproduction is most satisfactory. We are informed that the issue is limited to one hundred proofs, price one guinea each.

EMPIRE DAY.

LAST Monday was the fifth birthday of "Empire Day," and its observance in England was much more general than heretofore. Most newspapers dealt with the subject in a satisfactory spirit, but it is quite in accordance with the eternal fitness of things that the efforts of all of them should have been eclipsed by the *Times* itself. That paper published a special supplement of no less than forty-seven pages, illustrated by maps specially drawn so as to bring out the true proportions of the British Dominions, the extent to which the outlying portions are inhabited, the means of communication, the distances from one to the other, and the fashion in which they are linked together for purposes of defence and the development of commerce. The production was a monumental feat of journalism. To watch with satisfaction the increasing recognition of Empire Day it is by no means necessary to be a political Imperialist. On more than moral grounds it is well to instil into the young a feeling that they have duties to others than themselves—that their lives and the fashions in which they lead them are of importance to the family, the village, the county, the nation, and the Empire at large; while the purely physical outcome is equally valuable. Apart from the hundreds of thousands of children who on Empire Day are taught to grasp at an elevating abstract conception quite outside the routine of their daily work and lives, there are thousands of boys and hundreds of girls who, as the outcome of the spirit which has brought this national festival into existence, are being led to engage in far healthier amusements than those which would otherwise occupy their spare time. It is easy to smile at the sight of strings of girls in khaki hats, belts, and the like, but for every one of those girls a hundred boys are being taught to enjoy exercise in the open air, and are having their intelligence, powers of observation, and sense of discipline and duty awakened and cultured in a thousand and one different ways. Even already the good effects are seen, as witness the array of some 5,000 children who on Monday afternoon marched from the Embankment to the review in Hyde Park. They were as healthy and bright-looking a lot of youngsters as any one could desire to see. On such grounds alone all thoughtful medical men are likely to favour the keeping Empire Day, while no member of the British Medical Association can possibly deny it his approval. For him the celebration has a special and direct significance, for he belongs to a body which is in itself an important link between the several parts of Greater Britain. In spite of the fact that no one can belong to the British Medical Association who is not either on the *Medical Register* of Great Britain and Ireland or of the colony in which he resides, it has its corporate or individual representatives in every inhabited quarter of the globe. In the East it has Branches in several parts of India, and in Assam, Burmah, Ceylon, and Singapore; in the West on the mainland of Central America and the neighbouring islands; while in Canada it has

numerous Branches. The same story is true of the Australian Commonwealth and its component States, of New Zealand, and Tasmania, and the other great colonies in South Africa; of Hong Kong, of Malta, Gibraltar, and many other spots. Moreover, there are many hundred members who, though unable to take an active part in its affairs, because resident in foreign countries or too far away from any Branch or Division, yet keep up their relations with their fellows in Great Britain and elsewhere through the medium of the *BRITISH MEDICAL JOURNAL*.

A CHRISTIAN SCIENCE LECTURE.

A CORRESPONDENT writes: Seeing a lecture on Christian Science, by a Dr. Francis J. Fluno, "billed" at the Queen's Hall on Monday evening, I had the curiosity to go to hear it, and I send you my impressions. In regard to Christian Science, I am one of the "profane," but, like the man who prayed to the devil on the principle that it is prudent to keep well with both sides, I went prepared to pick up any hints that might be useful on occasion. The large hall was filled, members of the "devout female sex," as the Catholic Church politely calls it, being, as far as I could judge, in a proportion of about 6 to 1 of the other. The audience was a well-dressed crowd; and if it is to be taken as representative of the new revelation, it may be inferred that the gospel according to Mother Eddy is not preached to the poor. As for the lecture, or rather sermon, it was, without exception, the dullest to which it has ever been my fate to listen. The lecturer, a gentleman of venerable appearance, who was described by his introducer as having abandoned the science of medicine for the science of Christianity, spoke in a dismal, monotonous drawl, which was listened to with a patience which was the most Christian feature in the affair. As for the substance of his discourse, like Gratiano, he spoke an infinite deal of nothing, and he spoke it over and over again. Now and again there were flashes of that mechanical humour which the vulgar American reproaches us with not understanding, not seeing that we think it silly. Thus we were told that there is no more feeling in nerve than in a shoe string, and no more strength in a muscle than in a dishcloth; that honesty is the best policy, but policy is not the best honesty. These are some of the gems of wit, for which the lecturer—sometimes after waiting a moment—got a rather thin laugh. The discourse in general was nothing but the recital of a series of propositions, truisms, platitudes, nonsense, and blasphemy, mixed in about equal proportions. There was no explanation, no proof, no evidence, no argument—nothing but dogmatic assertion and the endless repetition of meaningless formulas. "Truth is positive, error is negative"; "God is omnipotent and omnipresent"; "love is positive, hatred is negative"; "there is no heaven except here and now"; "there is no hell except here and now"; and so on. We were told that we must get rid of belief in hell, yet rather inconsistently we were instructed how to fight the devil. Disease, like sin, is a delusion—a comfortable doctrine which must make life easy to those who can make-believe enough. Matter is an error of "mortal mind." I cannot give a better idea of the lecture than by quoting what the American ladies said on an occasion described in *Martin Chuzzlewit*: "'To be presented to a 'Pogram,' said Miss Codger, 'by a Hominy, indeed, a 'thrilling moment is it in its impressiveness on what 'we call our feelings. But why we call them so, or why impressed they are, or if impressed they are at all, or if at all we are, or if there really is, oh gasping

"one! a Pogram or a Hominy, or any active principle to which we give those titles, is a topic, "Spirit searching, light abandoned, much too vast "to enter on, at this unlooked-for crisis." "Mind and matter," said the lady in the wig, "glide swift into the vortex of immensity. Howls the "sublime; and softly sleeps the calm Ideal, in the "whispering chambers of Imagination. To hear it, "sweet it is. But then, outlaughs the stern philosopher, and saith to the Grotesque, "What ho! "arrest for me that Agency. Go, bring it here!" "And so the vision fadeth." In the lady in the wig the prophetic soul of Dickens seems to have foreseen Mrs. Eddy. Dr. Fluno's discourse would have been an excellent soporific, but for the obsessing delusions of an uncomfortable seat and the painful cough of a lady near me, who, I suppose, had not attained the fullness of faith necessary to salvation from such unreal troubles. As far as I could gather from the lecture, the whole teaching of Christian Science is that man should bury his head in the sand like the foolish ostrich, and lull himself into forgetfulness of the fact that there are such things as sin, sorrow, and suffering all around him. Christian Science, we were told, covers the whole ground; if it cannot do everything it can do nothing; if it cannot do everything for every one, it can do nothing for any one. Yet the speaker made no appeal to humanity: no word did I catch of sympathy with distress, of self-sacrifice, of effort to lighten the burden of life for those on whom it presses heavily. People homeless and starving, the holocaust of infant life, the suffering men and women in hospitals and sickrooms, seemed to be put out of sight and out of thought. The aim of the Christian Scientist—if he acts on his belief—is to lap himself in a selfish dream, in which the anxieties, worries, and duties of life cease to trouble him. Every heroic element is eliminated from humanity; every belief, every hope that has supported man in the struggle to conquer the blind forces of Nature which war against him, is treated as error. Carried to its logical conclusion, the doctrine would abolish science as well as religion, and would bring about the state of things described in the closing lines of the *Dunciad*:

Lo! thy dread Empire, Chaos, is restored;
Light dies before thy uncreating word:
Thy hand, great anarchy! lets the curtain fall,
And Universal Darkness buries all.

THE INCIDENCE OF CANCER.

PROFESSOR ORTH has recently published statistics, based on data gathered in the Pathological Institute connected with the Charité in Berlin, relative to cases of cancer dealt with by Virchow between the years 1875 and 1885 and by himself from 1904 to 1908.¹ While admitting that statistics of this kind may be fallacious in various ways, he believes that they may, if properly analysed and collated, be of considerable use. The percentage of cancer cases among all the autopsies appears to have increased steadily. In 1875 it was 4.9 per cent.; in the following years the number rose almost regularly until 1883, when it was 7 per cent.; while in 1884 and 1885 it remained practically stationary (7.2 and 7.0 per cent.). In 1904 it was 10.7 per cent.; in 1905 it rose to 11.27 per cent.; in 1906 and 1907 it was just above 14 per cent.; and in 1908 it was 12.2 per cent. Professor Orth believes that these figures show a real increase in the incidence of cancer, for, as he points out, the means of detecting carcinoma and other forms of malignant disease pathologically have not altered during the years concerned. With regard to the situation of the tumours,

he finds that no change has taken place. Thirty years ago, as to-day, the most common sites were the uterus and the stomach. Cancer of the liver, occurring as a primary disease, was found only twice in the last five years. He is of opinion that clinical diagnosis is very imperfect, and quotes from the Registrar-General's Annual Reports, in which he finds from 13.2 to 14.3 per cent. of all malignant tumours entered as liver cancer. This indicates a frequency of occurrence 50 times as great as that—that is, 0.28 per cent.—found in the Pathological Institute. Taking only adults of over 20 years into consideration, he found that 14 per cent. of all the males and 20 per cent. of all the females showed cancer as the cause of death. The female sex, however, is not so frequently attacked by cancer, if cancer of the sexual organs is excluded. He further points out that the extreme rarity of cancer of the penis—only two cases in men aged 65 and 77 years respectively—is opposed to the infectivity of the disease, since cancer of the gravid uterus is by no means uncommon. Lastly, Professor Orth gives a table showing the average age at death of cancer patients, arranged according to the situations of the tumour. There are no great variations in the various years, and the age 50 appears to be the one around which most of the averages turn.

WATER AND SEWAGE PURIFICATION.

THE Ohio State Board of Health is evidently doing good work in procuring the purification of water supplies and of sewage, the results of which are set out in a voluminous official report.¹ This report is the outcome of an Act of the Legislature, which directs the Board of Health to undertake the duty of investigating these matters—a duty which our own Royal Commission suggests should be laid upon the central authority which they propose should be set up. This is another instance of the difference in method adopted abroad in dealing with such matters. At home individual communities are left to work out their own salvation and to learn from their own mistakes, while in Germany and in America there are properly equipped central bodies which undertake to advise and direct, and, above all, to educate, a point strongly insisted upon in this report. In Ohio they go farther than this. The Legislature has enacted that no new public water supply or sewerage system nor any extension of an existing system shall be carried out without the approval of the Board of Health. Here, on the other hand, our laws permit of new sources of pollution being set up without let or hindrance. With regard to water purification, it is stated that 70 per cent. of the population dependent on public water supplies are provided with water from polluted sources, so that the efficiency of the treatment of the water is of vital importance, but as yet only 30 per cent. of the urban population are supplied with filtered water. Owing probably to the turbidity of the rivers the method of filtration most favoured is that of mechanical or pressure filters, and the new Cincinnati plant is said to be the largest of this kind in the world. In connexion with these filters the use of coagulants is dealt with, but nothing seems to have been done towards investigating the effect of storage of the waters, nor is any mention made of sterilization of drinking water. In sewage purification the Ohio authorities have arrived at the opinion, which has now for some time been prevalent at home, that owing to scarcity and cost of suitable land dependence must be placed chiefly upon artificial methods, but as yet there are

¹ *Berl. klin. Woch.*, March 29th, 1909.

¹ Official Report of an Investigation of Water and Sewage Purification Plants in Ohio. Columbus, 1903. (Octavo, pp. 883.)

only forty-six sewage works in operation or under construction, dealing with the sewage of 12 per cent. of the urban population. The recent schemes are said to provide largely for septic tanks and sprinkling filters, but at the date of the investigation there was no completed sprinkling filter plant. An interesting account is given of some experiments in the disinfection of sewage with copper sulphate and chloride of lime. The various water and sewage works are described in detail with many illustrations. On the whole there is little new information to be gleaned by the English engineer, and in considering the results obtained the difference between English and American problems must be kept in mind. For instance, in one town the water supply is said to be nearly 500 gallons a head, and the sewage flow 246 gallons. The report shows, however, that the Board of Health is very active in its own sphere of work, and successful in inducing the communities in the State to carry out the necessary works for dealing with both drinking water and sewage. With such ample power as it seems to possess, and with a field of labour comparatively virgin, future reports should be extremely interesting and useful.

"KNOWN TO THE POLICE."

THE police-court missionary sees a certain phase of humanity, and the account which Mr. Thomas Holmes has given of his experiences deserves notice. It is satisfactory to observe that he unhesitatingly admits an improvement in the condition of the police-courts and the arrangements connected with them. He speaks of a time when all the prisoners waiting to be brought before the magistrates were put in a common room with no separation of the sexes—men, women, and children, some of them more or less intoxicated, many of them brutal and offensive in their behaviour. The courts are better lighted, better ventilated, and the old disreputable, beery solicitor of the type of Mr. Pell has disappeared; even the prisoners have in a way improved. It was formerly common to see a prisoner on the verge of delirium tremens, but Mr. Holmes says that he never sees such cases now, although his explanation is not satisfactory, for he thinks that the modern man can stand less drink; he gets drunk more quickly and recovers quickly. He thinks that the prisoners have changed in other respects, not altogether for the better. The old-time prisoner had more character, grit, pluck, and personality, and often had a keen sense of humour, but now they are cleaner and less brutal, but weaker; weakness, not wickedness, is their great characteristic. There are fewer crimes of violence, less brutality, less debauchery, less drunkenness, but more dishonesty. In Mr. Holmes's opinion, the Inebriates Act has worked badly, because the necessary condition of being convicted four times for drunkenness during the same year has limited its application almost entirely to one class—namely, that of drunken prostitutes, whom he regards as hopeless; while respectable women, who might be reclaimed from their intemperate habits, rarely come under the terms of the Act. He points out that a very considerable proportion of the women committed to inebriate homes under the Act are not sane, and he holds it absurd to treat such cases in these institutions. Another evil of recent legislation is the power given to a husband to put his drunken wife homeless on the streets, and it is somewhat alarming to know that up to the end of 1906 there had been granted no fewer than 72,537 separation orders. Mr. Holmes is a severe critic also of police-court marriages, and maintains

that a magistrate who puts pressure upon people to unite in this bond takes upon himself a grave responsibility. Mr. Holmes complains also of inequality of sentences and the uncertainty of punishment, and refers to vagabonds and scoundrels who by their apparent candour and flashes of humour continually save themselves from anything approaching a long sentence. Many young men are brought up on trifling charges, sometimes for stealing, sometimes for begging, with a long catalogue of convictions against their names; they seem unable to work steadily at anything; sometimes they may have been in the militia, but they have never learnt a trade and are hopeless members of society. Mr. Holmes, regarding discipline as essential, would put them in the army in special regiments, though the army at present is not a good training school for industry, as time-expired men form a large proportion of the casual labour class which too often recruits the "unemployed." He thinks much would be done by raising the school age to 16, and by making attendance at continuation schools compulsory, and would forbid any one under the age of 20 to be served with drink in a licensed house. We applaud his suggestion that public playgrounds should not be orderly places with notices "not to walk on the grass," but open spaces for rough out-door games. He is also in favour of the reduction of the alcoholic strength of beer to 2½ per cent. and of spirits to 50 per cent. below proof, and he goes so far as to say that such a change "would usher in the millennium." This is, after all, a more practicable proposal than local option or prohibition, as either would be defeated by illicit sales; but we doubt whether such weak beer would keep sufficiently long to make it a commercial success, and so far the taste of the English working man has pronounced strongly against beer of the German type, which contains nearly 4 per cent. of alcohol. Although we agree that spirits as now sold are too strong, we are not sure that a reduction in strength would be effective, as they are normally drunk diluted, and if sold weaker would probably be swallowed much as they are now, but that less water would be added by the consumer.

RETIREMENT OF DR. TATHAM.

It has been thought that the occasion of the retirement of Dr. J. F. W. Tatham from the position of Superintendent of Statistics in the General Register Office affords a fitting opportunity to his friends to show their appreciation of his great services to public health by entertaining him at a dinner which, it has been arranged, shall be held at the Grand Hotel, Charing Cross, on Thursday, June 17th, at 8 p.m. Sir Shirley Murphy has consented to preside, and a number of those who are associated with public health work have already intimated that it is their intention to be present. Dr. Hamer will be glad to receive at 55, Dartmouth Park Hill, N.W., the names of any of Dr. Tatham's friends who have not already communicated with him. The price of the dinner tickets is 1 guinea, inclusive of wine.

AUSTRALIAN INSTITUTE OF TROPICAL MEDICINE.

THE Australian Institute of Tropical Medicine is about to appoint a director. The objects of the institute are to further the scientific study of the diseases peculiar to tropical Australia, and to afford opportunities for the training of medical men in this department of medicine. The institute will be situated in Townsville, Queensland, and the committee of the large and well-equipped general hospital

1 Known to the Police. By Thomas Holmes, Secretary to the Howard Association. London: Edward Arnold. 1908.

there has undertaken to set apart, free of charge, an isolated building in the grounds of the hospital as an institute for the work of investigation of the diseases in question, and to maintain in the main wards of the hospital, also free of charge, patients under special observation who may be suffering from diseases other than those specially excluded by the provisions of the Queensland Health Act, and to give every facility for clinical observation to the officer in charge of the institute. The director will be required to devote his whole time to the work of the institute, and—subject to the general control of a committee appointed by the Universities of Sydney, Melbourne, Adelaide, and the Government of Queensland—will be required to organize and administer the institute, to conduct investigations into the tropical diseases of Australia, to give instruction in tropical diseases, and to superintend research work undertaken in the laboratories of the institute. The appointment is for five years, and the salary will be £800 a year. Further particulars will be found in our advertisement columns, and it will be sufficient to add here that applications, accompanied by six copies of testimonials, should be received by Dr. C. J. Martin, F.R.S., Director of the Lister Institute for Preventive Medicine, Chelsea Gardens, London, S.W., not later than July 10th. The selection of the director will, in the first instance, be made by a committee composed of representatives of the Royal Society and the London and Liverpool Schools of Tropical Medicine. The Government of Queensland and the committee of the Townsville Hospital are very much to be congratulated on the wise public spirit shown in establishing this institute, which will afford to the director and those who will have the opportunity of working there remarkable opportunities of extending our knowledge of the etiology, pathology, and treatment of tropical diseases, a department of medicine which, though it has made enormous progress during the last decade, still affords endless opportunities for further discoveries.

INTERNATIONAL ANTIVIVISECTION CONGRESS.

An International Antivivisection Congress is to be held in London on July 6th and four following days, under the presidency of Sir George Kekewich, K.C.B., M.P. Miss Lind-a-Hageby is the Honorary General Secretary. Lord Lonsdale, whose name was announced as Honorary Treasurer, has resigned that position, as well as the Honorary Treasurership of the International Antivivisection Society, on the ground that since he accepted these offices he has learnt that the object of the Congress is the total abolition of vivisection. "In this," says Lord Lonsdale in a letter to the press, "I am afraid I cannot acquiesce, for my feeling, after most careful inquiries, has always been that vivisection is an absolute necessity in the interests of human life, with a view to minimize the sufferings of those who have to undergo operations necessitated by accidents or arising from various diseases." He adds that "vivisection should be strictly limited, and no certificates should be given to other than those of the highest order of scientific research."

BERLIN PROFESSORS AND RUSSIAN PATIENTS.

REFERENCE was made in the JOURNAL of April 10th to certain alleged breaches of professional ethics by some Berlin professors, who were accused of bribing various persons to induce wealthy Russian patients to place themselves under their care. Geheim Rat Professor Dr. Senator, against whom, among others, the charges of offering bribes to the porters at the Russian Institute and at various hotels for the

purpose of gaining patients were brought, has found it necessary to institute proceedings for slander against the *Berliner Zeitung am Mittag*. The case was heard at the Moabit Court in Berlin on May 11th. Professor Senator said that he had no special reason to attack that paper, but that he had to protect his professional and private character. The judge made the suggestion that the defendants should offer a public apology and explanation. This apology was to the following effect:

I have been convinced by the evidence taken this day that the small fees paid, according to the statements of the plaintiff and of the witnesses, by the plaintiff to interpreters in rare exceptions were not paid as bribes or as payments for bringing patients to him, nor can such payments possibly be construed in this sense. I retract all that I said in the article that could be construed as accusing the plaintiff in this manner, and undertake to bear the cost of the action.

The next step in the matter is the inquiry into the charges brought against several consultants by the medical ethical court. Before the case is heard, before all the evidence has been given, and the various aspects have been considered, it would, of course, be most improper to express any opinion on the general subject. We may be allowed to say, however, that the tactics of those political newspapers which give currency to scandals, but keep silent when the reputations of those charged with unprofessional conduct are cleared, seem to us highly discreditable.

VAGINAL HERNIA AFTER TOTAL HYSTERECTOMY.

MUCH is written about the good results following total removal of the uterus for prolapse, and panhysterectomy for uterine fibroid. Unfortunately, as certain writers of experience have pointed out, the operator is not always careful about following up his cases. Wertheim's operation and all other procedures for malignant disease of the uterus need not be discussed, as the surgeon is generally interested in looking out for recurrence. It is otherwise when the womb is removed for the remedy of the two far less grave classes of diseases above mentioned. Some instances of vaginal hernia have recently been related by Küstner and Gerschun,¹ and they should not be overlooked, as they teach us that this distressing complication is not rare when the uterus has been removed. Those who report these bad after-histories maintain that vaginal hernia should, on the strength of present experience, be anticipated; in other words, when the uterus is extirpated, the vault of the vagina should be sutured to the abdominal wall above the bladder. Küstner reports one case, aged 59 years, under his care in 1904, which had been subject to prolapse for over eleven years. In 1893 the uterus was removed, but prolapse of the vagina recurred very soon afterwards. At length the patient began to suffer badly from cystitis and incontinence of urine. There was inflammatory infiltration in the vesico-vaginal region. Küstner operated through the abdomen; the vault of the vagina was drawn upwards with some difficulty, and the bladder raised and fixed by suture to the parietal peritoneum. The cystitis and other distressing symptoms disappeared at once. Küstner bearing this case in mind, when performing abdominal panhysterectomy for fibroid in a later case, when the uterus had been detached completely from its connexions, fixed the upper end of the vagina to the parietes, employing four catgut sutures and one silk thread. The patient recovered, but her after-history was not known, and in the discussion which followed the reading of Küstner's report it was pointed out

¹ Küstner, *Zentralbl. f. Gynäk.*, January 15th, p. 113; Gerschun, *ibid.*, March 13th, p. 381.

that the vaginal canal, however treated, short of extensive resection, tended to prolapse. Gerschun of Kieff more recently reported a case of vaginal hernia in a woman aged 48, who had undergone removal of the entire uterus for prolapse seven years before she came under his care. The vagina began to protrude from the vulva within a year after the hysterectomy. There was also a right inguinal hernia. In a photograph with which the report is illustrated the scar marking the line of detachment of the cervix from the vagina seven years previously is seen on the surface of the vagina, giving it the appearance of a cervix with a fissured os protruding from the vulva. Bassini's operation was performed for the cure of the inguinal hernia, and the operator attempted to push the vault of the prolapsed vagina upwards against the incision in the groin and to fix it there; failing in this, he opened the abdomen in the middle line, pushed the vagina up, and fixed it to the lower angle of the wound by two silk sutures passed through the muscle, aponeurosis, and peritoneum. Unfortunately, no after-history was given in this interesting report. Gerschun insists that the right treatment for prolapse is ventrifixation of the uterus followed by extensive resection of the vagina. These reports appear to prove that when a uterus is removed recovery from the operation by no means signifies permanent cure, indeed discomfort and worse complications may follow, so that the patient's condition may even be more unfavourable than it was before the fibroid was removed or the prolapse temporarily relieved. There are also psychological conditions associated with removal of the uterus, which must not be overlooked. Above all we must insist that long series of after-histories is urgently demanded.

THE MEDICAL LIBRARY ASSOCIATION.

THE Council of the British Medical Association has arranged to grant facilities to the Medical Library Association to hold its first meeting during the annual meeting of the Association in Belfast next July. A loan exhibition illustrating medical libraries and medical literature is being organized in connexion with this meeting: and the honorary secretaries, Dr. I. Walker Hall and Mr. Cuthbert E. A. Clayton, to whom communications may be addressed at The University, Manchester, are particularly anxious to receive specimens of the following: (1) MSS. and early printed books; (2) first editions of noteworthy books; (3) early Irish printed books there are few, if any, before 1700; (4) books on tuberculosis; (5) books upon Celtic medicine; (6) photographs of libraries; (7) statistical diagrams giving number of volumes, issues, readers, income, etc.; and (8), library papers, rules, etc. The Library Association will insure all loans, and will carefully guard them.

MEDICAL MEMORIALS.

It has been decided that the memorial to Dr. William T. Bull, the late eminent surgeon of New York, shall take the form of the creation of a large fund for the prosecution of original research under the auspices of the College of Physicians and Surgeons. It is hoped that £100,000 may be raised for the purpose. How much more suitable is such a memorial to a scientific man than the usual statue which is too often an eyesore, in any case useless, and inevitably doomed to more or less early decay, whereas research continues and develops the work done for mankind by the man who is commemorated, and keeps his name living among those who follow in his footsteps.

MILK AND DAIRIES BILL.

THE bill to make better provision with respect to the sale of milk and the regulation of dairies, introduced by the President of the Local Government Board on Tuesday, has now been printed. Its main objects are to provide for: (1) The more effective registration of dairies and dairymen; (2) the inspection of dairies and the examination of cows therein; (3) the prohibition of the supply of milk from a dairy where such a supply has caused, or would be likely to cause, infectious diseases, including tuberculosis; (4) the prevention of the sale of tuberculous milk; (5) the regulation of the importation of milk so as to prevent danger to public health arising therefrom; (6) the issue of regulations for securing the supply of pure and wholesome milk; (7) the establishment by local authorities in populous places of milk depôts for the sale of milk specially prepared for infants.

SPAS AND HEALTH RESORTS.

FOR some time past a place has been reserved in the advertisement columns of the JOURNAL for a list giving brief particulars of baths and health resorts at home and abroad, which it is believed will be found useful by practitioners who may wish to recommend patients to undergo one of the numerous cures which are offered by more or less enterprising municipalities. With regard to the choice of health resorts, as in other matters, we are all apt to fall into grooves, and the list will often afford useful suggestions or call to mind the name and properties of places which may have passed out of memory. There are, of course, many works of reference which profess to give complete lists and full particulars of such places, but they cannot always be up to date. There is also no lack of literature circulated by individual resorts describing the particular advantages claimed for them, but such literature we suspect usually very speedily finds its way into the wastepaper-basket, for the bulk of the circulars received by medical men in this country from health resorts, chemists, and makers of appliances is so huge that it is physically impossible even to preserve it, much less to attempt to classify it. Under these circumstances the standing notices in the JOURNAL will, we believe, be found serviceable.

MR. ALBAN DORAN has been elected an honorary member of the Leipzig Gesellschaft für Geburtshilfe und Gynäkologie and a foreign corresponding member of the Sociedad de Obstetricia y Ginecologia de Buenos Aires.

It will interest members of the British Medical Association to know that there is an intention to invite the Association to hold its annual meeting in Birmingham in 1911, and that a similar invitation will be extended from Liverpool to hold the annual meeting of 1912 there. At present no definite arrangement has been made with regard to next year—1910.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Doctors and the Motor Car Tax.—In the course of the debate on May 20th on the Budget resolution imposing the motor car tax, the proposed rebate to medical men was the subject of comment from several speakers. Sir Henry Norman, in suggesting that the Chancellor of the Exchequer might add slightly to the sums to be derived from the taxation of motor cars, said he hoped he had as much sympathy with the noble profession of medicine as anybody else had, but for the life of him he saw no more reason why a doctor's car should be exempted from taxa-

tion than the car of any other professional man. The builder, the surveyor, the commercial traveller, and, above all others, the veterinary surgeon, had certainly as much right to be relieved as the doctor of taxation, and the veterinary surgeon very much more so, because he had always to go to his work, whereas a good deal of the doctor's practice came to his own front door. It was true that the medical profession, to their very great honour, gave much precious service gratis or for next to nothing, but, on the other hand, the possession of even the smallest car would enable the doctor—if he had the other qualifications—to practically double his practice. Why should they be relieved of a few shillings of the cost, for it could only be a few, on an object which would enable them greatly to increase their incomes. A doctor of small means would certainly use a car of under 12 h.p., which was a most serviceable vehicle, and as that doctor under these proposals would have to pay 31s. 6d. instead of 2 guineas, if given a rebate of one-half, the Chancellor of the Exchequer was making him a present of 10s. 6d. That could not be said to be any great boon to the poorest members of the medical profession, and it was hardly worth the trouble. The doctor who used a powerful car, which, probably, the ladies of his family used for their own purposes, could well afford to pay the increased licence of 6 guineas instead of 2, which would only mean two visits of 2 guineas each. If the Chancellor did not see his way to abandon what he ventured to describe as unjust and unreasonable relief, he would strongly urge him to limit it to cars of 12 h.p. because there could be no reason for giving any relief to a doctor who could afford to own and use a valuable car. Mr. Markham took the opposite view. There were a great many doctors earning a very small income in country districts, and who worked extremely hard for it. A motor was a matter of great convenience to them and to their patients. Mr. Catcart Wason said he thought those who knew the life of the poor country doctor and the difficulty he had in getting about the country would appreciate this point. He thought he might say that as a rule country doctors used very low horse-power cars, and he thought it would be no very great sacrifice to exempt these cars altogether. They were propelled by 16 h.p. They were generally used by doctors, who in Scotland led a very hard life, and anything the Chancellor of the Exchequer could do to make life easier, both to them and to the poor people whom they visited, would be gratefully received. Question after question had been addressed to the Chancellor of the Exchequer with regard to lightening the burden in other respects, and he thought the right hon. gentleman would be doing a great public service, both to the doctors and to the poor people in the North, if he could make a concession in regard to these cars. Mr. Lloyd George, in replying at the close of the debate before the Budget resolution was carried, said that the doctor had been excepted for a humanitarian reason. He thought it was very desirable that there should be a difference from the point of view of the person who lived in a remote district where people had to travel four, five, or ten miles for a doctor, and where the difference of an hour in his arrival might mean the difference between life and death, or the alleviation of pain and misery. Therefore he thought the doctor was entitled to some exemption, and, if necessary, it should be substantial. That was really why he had not been able to consider the other claims for abatement which had been put before him in regard to others who did not come into the same category as the doctor.

The Profession and the Motor and Petrol Taxes.—Last week Mr. Vincent Kennedy asked the Chancellor of the Exchequer to consider favourably the remission of the petrol and motor taxes in the case of Irish dispensary doctors. Mr. Lloyd George replied that as at present advised he did not think there were sufficient grounds for granting doctors further concessions in addition to the rebate, which he had already proposed, of half the licence duty on their motor cars. Mr. Hugh Barrie then asked if veterinary surgeons could not receive the same rebate on petrol as medical men, and Mr. Lloyd George said he had not proposed to allow the medical profession a rebate upon the petrol used by them. As he had already explained, he did not see his way to extend to veterinary surgeons the rebate of half the licence duties allowed to

doctors on their motor cars. Major Anstruther-Gray asked whether the right hon. gentleman was aware that the petrol used on the average by medical men would amount to something like £12 a year? No reply was given.

Medical Officers (Elementary Schools).—Mr. Summerbell asked the President of the Board of Education if he could state how many medical officers for elementary schools had made reports to his Department; and whether it was the intention of the Government to issue a report in regard to the same, giving the number of children examined and particulars as to their general health, and also reforms, if any, recommended by such medical officers. Mr. Runciman answered that about 130 reports had been received up to the present date. The Board contemplated the issue of a report in due course on the work of medical inspection, but he was not in a position to indicate precisely what the contents of the report would be.

Seizure of Imported Meat.—In reply to Mr. Starkey, Mr. Burns said that he found that the meat recently seized at Grimsby included two diseased carcasses of calves which, though they did not themselves bear the official label guaranteeing that they had been inspected by officers of the Netherlands Government, were packed amongst several healthy carcasses which were so labelled, in a crate which itself bore an official label. He was in communication with the Consul-General of the Netherlands with respect to the matter.

Medical Fees for Yeomanry Recruits.—Mr. Meysey-Thompson asked the Secretary of State for War what remuneration was paid to medical men, other than army surgeons, for cases in which recruits for the Yeomanry did not pass the medical examination. Mr. Haldane said that a capitation grant per recruit enlisted was paid to county associations. The remuneration of the doctor who examined candidates for the Territorial Force was paid by the associations from their funds, and was fixed at their discretion.

The Infectious Diseases Hospital, Stornoway.—Mr. Weir last week asked the Lord Advocate if he was aware that the recent report of the medical officer of health for Ross and Cromarty called attention again to the fact that the hospital was in urgent need of a water supply, and, in view of the danger to patients, he asked what steps would be taken. Mr. Ure said he was aware of the statements referred to, but he could only refer to his answer of March 9th to the effect that in the present financial condition of the Lewis District Committee there was no immediate prospect of making this improvement. Mr. Weir then asked if he was to understand that the Secretary for Scotland and the Local Government Board for Scotland were so utterly indifferent that they intended to discard the Public Health Act. Mr. Ure replied that the Secretary for Scotland was not discarding the Public Health Act. The Local Government Board had no power.

Opium Exports from India.—In reply to Dr. Rutherford, Mr. Hobhouse stated last week that the figures were: 1905, 63,053 chests; 1906, 65,617 chests; 1907, 63,415 chests; 1908, 62,408 chests. In 1909 the export would be limited to 56,800 chests. In accordance with the arrangement made with China, the export of opium from India was being reduced by 5,100 chests per annum. This was with effect from 1908, the average export for the five years ending 1905 being taken, as suggested by the Chinese Government, as the basis of the calculation.

Epidemic Disease among Soldiers in India.—Mr. Buchanan, in reply to Sir William Collins, stated that the Government of India would be asked to furnish a return of the number of cases and deaths, and corresponding rates per thousand, of enteric fever, cholera, plague, and small-pox respectively in the native army and among the European troops in India in each year from 1900 to 1908.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

OLD AGE PENSIONS FOR IRISH DOCTORS.

LET it not be supposed that a paternal Government has been moved by a sense of justice to grant to Irish dispensary doctors superannuation. So far as we know, nothing is farther from their thoughts; but all the same, the old age pension scheme has proved a blessing in disguise to many an Irish rural practitioner. We think it was the Chancellor of the Exchequer who stated in the House that the number of persons apparently eligible for old age pensions in Ireland was 127 per cent. of the estimated population over 70 years of age, and it is really extraordinary how many Irish peasants have discovered they were over 70 on the first day of this year.

In many parts of Ireland a large percentage of the farmers' houses have one or more old age pensions coming in. If a peasant farmer cannot sufficiently trust his son or daughter to assign his farm to one of them outright, he only gets a pension for his wife; but if he assigns the farm, then both get it—a very satisfactory arrangement.

Hitherto, when old folk of this class who were past work got sick unto death it was "the will of God," and unless a red ticket could be got for the dispensary doctor, they were mostly permitted to depart in peace; indeed, the old folk themselves were frequently the chief objectors to such unnecessary expense as paying a doctor for them; and for this reason, as has been stated on many previous occasions, a large proportion of the deaths among the Irish peasantry are recorded as uncertified.

But all this is changed. The old age pensioner, being a person in receipt of £13 a year, probably with a well-stocked farm in addition, seldom has the audacity to demand a red ticket or pose as a "poor person," under the elastic definition of that class accepted by the Irish Local Government Board, and, besides being an asset of cash value, it is worth paying the doctor or promising to pay him for his attendance.

The result is that now the doctors are called to see, and, unless they have more of the innocence of the dove than of the wisdom of the serpent, are paid for visiting the pensioners who fall sick in their respective districts, and in this way are getting a share of the old age pensions a paternal Government never intended for them.

The spring of 1909 has been very fatal to old people in Ireland as elsewhere, but the effect in Ireland has been to make these very superstitious people regard the old age pension as an unlucky gift from the hated Saxon with some ulterior design upon their lives, and we should not be surprised if it had the effect of checking the applications—at least, for a time; at any rate, people in Ireland are chuckling over this unexpected plan for robbing the Saxon "hen-roost." That there is a vast amount of fraud is stoutly maintained by some and as vehemently denied by others; but one thing is obvious, and that is that the really poor—those who are past work and whose poverty has compelled them to accept the shilling or eighteenpence a week grudgingly granted them out of the rates—are left out in the cold—a real injustice to Ireland. However, as England is paying the bulk of the pensions, Irishmen have no great cause to complain.

TUBERCULOSIS AND SEASIDE RESORTS.

In our last issue we reported the protests of the inhabitants of Sutton and Howth against the proposal of the Women's National Health Association of Ireland to utilize the vacant coastguard cottages at this station as health homes in connexion with the tuberculosis campaign. The Countess of Aberdeen, as President, has since intimated through her secretary that the Association "have decided not to apply for the disused coastguard station at Baldoy, as, after inspecting it, it was decided not to be suitable for their purposes." It is not clear whether this letter also applies to the question of Sutton and Howth. Sutton and Baldoy are immediately adjacent, and it would seem that the same objections apply to the employment of the coastguard cottages in either.

Mr. John Lentaigne, President of the Royal College of Surgeons of Ireland, has addressed to the Dublin news-

papers a letter in which he says that the opposition is due to unreasoning panic, and calls attention to the fact that Lady Aberdeen has given a guarantee that no advanced cases shall be sent to the health homes, and that any patients sent will be made to observe all the special precautions which it is known can insure immunity from danger. He says:

A properly managed sanatorium for tuberculous patients is not a danger to the inhabitants of the district, but, on the other hand, a private house in which one case of consumption in the advanced stage resides without taking the precautions which we know can prevent the spreading of the disease is a source of real danger to the neighbourhood. The previously healthy residents in and near properly managed hospitals and sanatoriums for tuberculosis are not more likely to develop tuberculosis than other people living elsewhere. . . .

The London Brompton Hospital for Consumption, containing always over 300 cases, is situated in the midst of a well-populated and fashionable district, the buildings abut on the roadway, and the patients are constantly to be seen on the balconies in fine weather. There is no reason to believe that the health of the inhabitants of Brompton is injuriously affected, or that the rents of the houses are lower in consequence of the proximity of the hospital, and I remember well a statement by one of the medical officers of the institution that for a period of twenty-five years no nurse in the hospital had contracted tuberculosis. It is well to remember that the cases treated in this hospital are not the pre-tuberculous, or the slightly affected cases, such as the Women's National Health Association propose to send to Sutton—they are the severe well-marked cases which, if left untended and unmined, would certainly be a source of immediate danger to others.

To come nearer home, let us consider an institution that we in Dublin all know—the Royal Hospital for Incurables at Donnybrook. This hospital has forty beds exclusively for consumption, and may therefore be taken as an example. The patients admitted there are always advanced incurable cases, who can go anywhere about the neighbourhood on the days allowed for going out, yet there is no reason to believe that the neighbours are injuriously affected; certainly the rents of the houses in the district are not affected, and the lady superintendent informed me yesterday that she had never seen a case of tuberculosis arising amongst the nurses or staff in the hospital, although some of the nurses had been for ten years more or less in contact with these patients. As it is in these institutions so it is elsewhere. The argument against the health home is absurd, and would be ludicrous if it were not so tragic.

The tragedy lies in the fact that it is the poor people threatened with tuberculosis or actually slightly affected with the disease, and who are, therefore, all curable cases, who will, if this agitation goes on and succeeds, be deprived of the chance of cure now being provided for them in a way that is really safe and free from danger to the public. These poor people must then, in time, in their turn become chronic advanced cases, each a source of daily increasing danger to the people in their vicinity.

DUBLIN HOSPITALS' TUBERCULOSIS COMMITTEE.

At a meeting of the Committee held on May 21st, when Her Excellency the Countess of Aberdeen was present, and Sir John Moore occupied the chair, a report was submitted on the three months' work done by the two special nurses to look after poor consumptive patients in their own homes, placed at the services of the Committee by the Women's National Health Association. The number of cases attended was 198, including 69 new cases and 1,953 visits were paid. The number of deaths was 21, and 14 occurred in the patients' own homes. The amount of relief given to the parents and their families, in the way of nourishment, clothes, beds, etc., reflects the greatest credit on the Samaritan Committee, whose work in this direction is so commendable and practical.

THE MOTOR TAXES IN IRELAND.

A valued correspondent who knows, Ireland well sends the following notes:

The proposed taxes on motors and petrol will hit medical motorists especially hard, particularly the rural members of the profession, who are mostly dispensary doctors. The average country doctor in Ireland is a comparatively poor man, and if he has the means to buy and run a motor car, it is at a proportionally greater expense, as compared with the country doctors of his English brethren; indeed, the number of country doctors able to buy and run a car is very limited, and, if a dispensary medical officer, he can seldom do without a horsed vehicle as well, for there are but few districts in Ireland where he has not to travel by-roads too bad to take a motor over except at ruinous expense on tyres and machinery.

Again, he has more to pay for petrol than in England or near the large towns, because the dealers, having small demand, require larger profits.

Owing to the terrible state of the roads in all but a few counties his tyre bill is out of all proportion; the tyre that would live for 2,000 miles on the roads he must travel would be a

phenomenon. If he uses accumulators he must charge them himself, electric light plants being few and far between, and if repairs have to be executed the car or the parts must be sent away, local repairers are so few.

Still he might put up with the tax without much grumbling were he sure of getting any compensation in the shape of better roads, but he knows that the average county councillor is quite content with the roads as they are and will not spend an extra penny upon them if he can help it and even if a grant is made to be spent on the main roads it will be of little service to him for the bulk of his travels are on by-roads and boresms contracted for at about twopence a perch of seven yards, Irish measure.

Furthermore, in Ireland the motor is the only vehicle on which there is any tax at present, and if an additional tax is put on motors it will be adding to the manifest injustice on those members of the community who are trying to use them.

Motoring in Ireland is still only struggling for existence, and country doctors hesitate about going in for it on account of the excessive cost. In England it generally pays the doctor to motor, in Ireland it does not, and the taxes will put motoring out of the question for the ordinary dispensary doctors, who comprise nine-tenths of the rural practitioners.

Whether it is fair to mulct this already underpaid and over-worked class still further is a question, we suppose, too small to exercise the consideration of an English Chancellor of the Exchequer in want of funds, though a moment's thought would show him that if the better care of the poor is of any consequence dispensary doctors whose districts are so immense might well be encouraged to use this form of progression more freely, even to the extent of assisting them by a subsidy as some English county councils have assisted their surveyors to get over more ground than they could with horse traction. The great difficulty of medical practice in rural Ireland is to afford proper attention to patients over a wide area, and it is only by the adoption of motor transit, or an increase in the number of doctors and curtailment of the inordinate size of the districts, that this difficulty can ever be overcome. The motor would be the cheaper solution.

There is no hostility to motorists in Ireland, but most of the roads are unfit for use; the legal limit and the road hog is conspicuous by his absence. If the people are politely treated they are most friendly and obliging to the motorist; while as for the Royal Irish Constabulary, they are the best friends the Irish motorist has.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

POOR LAW MEDICAL OFFICERS.

THERE is some difference of opinion as to the real value of the game of cross-questions and crooked answers which nightly goes on in the House of Commons, but on the whole the evidence is in favour of the utility of addressing questions to the Parliamentary representatives of the various Government departments. To foil questioners by devising answers which admit as little as possible and promise nothing at all may afford intellectual amusement to permanent officials for a time, but it eventually palls, and departments as a whole dislike the atmosphere of suspicion thrown around them by constant questions, and commonly take steps accordingly. Hence the fact that Mr. Cathcart Wason again failed on May 15th to obtain from the Lord Advocate a satisfactory reply with regard to Poor Law medical work in Scotland, need not be taken to prove that no effect has been produced. The real question at issue is whether things are as they should be, or whether, on the contrary, the conduct of certain parish councils in some rural parts of Scotland towards their medical officers is not acting in a fashion seriously detrimental to the interests of the poor. It is safe to assume that the Lord Advocate is aware of the real nature of the question, but on May 15th, as on April 29th, he implied that no poor person in Scotland had ever failed to receive medical attendance because a Poor Law officer had been dismissed or had resigned in circumstances which made other medical men unwilling to take up the appointments. He indicated likewise that when vacancies occurred the temporary arrangements made to fill the gap were of a satisfactory nature. In the circumstances it might be well for the Lord Advocate to direct a specific inquiry on the point to every parish council in Scotland, and also to consider for himself to what period of time it is really reasonable to attach the adjective "temporary." Meanwhile, he might be asked to furnish a return showing the following: (1) In how many and in what places during the past three years have Poor Law medical officers

in Scotland been dismissed from their office or resigned owing to disagreements with the parish council, and what time in each case has elapsed before the appointments have been permanently refilled? (2) What periods have elapsed between the time that such resignations or dismissals have become effective, and the date at which temporary arrangements have been made for the performance of the duties required? (3) For what length of time in each case has it been necessary to maintain the temporary arrangements? and (4) during the continuance of those temporary arrangements what additional distances have the sick poor had to travel or send in search of medical attendance over and above the distances which would have been necessitated had a permanent medical officer been in office? Until and unless such a return is secured and proves satisfactory, the feeling must persist that, in addition to their other misfortunes, the poor of Scotland are being allowed to suffer for the shortcomings of their nominal guardians, and that the matter is not receiving the attention from the Scottish Office which its importance demands.

DUNDEE AND ITS SANATORIUM.

We have received the following letter:

Sir,—In your issue of May 15th your Special Correspondent has made statements as regards Dundee and its sanatorium which, I feel sure, will not be endorsed by every member of the medical profession. As is now a matter of history, the Dundee municipality determined to municipalize the sanatorium at Sidlaw in order, as they believed, to put the finishing touch to the stamping out process in the disease consumption. For one reason or other, however, the ratepayers rose up in arms against them, and at length succeeded in getting the municipality to withdraw their scheme. Your correspondent states that Dundee has thus thrown away the honour of being the first city in the kingdom to own a sanatorium for consumption.

I am not going to say a word about honour, but I desire to state that from the point of view of medical and social usefulness, I am one of those who are strongly of opinion that the Dundee people have done just as they ought to have done at the present time. Medically we know that the confident anticipations expressed more than a quarter of a century ago as regards the value of municipal isolation in infectious diseases of all kinds have not been fulfilled, and medically also we know that what infection danger a consumptive presents is dependent on individual conditions and surroundings rather than upon the disease. That is to say, that a consumptive who himself, or through his friends has the will and the power to exercise what is practically only cleanliness, is not a source of danger to the community at all. Sociologically, too, I hold that the municipalization of sanatoriums at the present time would be a mistake, inasmuch as it would tend to misdirect from its proper channels what energy a community can afford for its own improvement. Without disparaging in the slightest degree the value of the sanatorium in producing an arrest in the disease consumption, and so enabling the patient to plan out how he can best live what life remains to him, all experienced medical men must admit that the term "cure" in the sense that the laity understand it cannot really be applied to the results of sanatorium treatment. As was well put by a Dundee Town Councillor, "Municipalizing a sanatorium was like pumping a leaky ship: it may probably keep the ship a little longer afloat, but by directing what energy the community can afford towards the pumps rather than to the leaks, it will fail to use that energy to the best advantage."

The whole question of this ever-increasing municipal and State interference with the individual in disease is one which, I hold, requires very serious reconsideration. But this is far too wide a subject for discussion in this letter. Inasmuch, however, as silence on the subject of these interferences has been interpreted too much as meaning approval of them on the part of the profession, I beg to intimate to you by this letter that in my opinion there are many in the profession who believe that these interferences are already much too great, and who believe also that in this latest example of municipal interference in Dundee the people there have done wisely in acting as they have.

I am, etc.,
Edinburgh, May 24th.

ALEX. JAMES, M.D.

RUCHILL.

A small book entitled *Ruchill: A Romance: Almost a Tragedy*, has been published by one of the members of the Hospitals Committee. In it is traced the history of the difficulties at Ruchill from the first intimation of trouble on December 4th, 1907, to the recent decision of the Council that the physicians and superintendents of Belvidere and Ruchill Fever Hospitals should change places. The book is largely made up of extracts from the official minutes of the Town Council, Hospitals Committee, etc., and the author, ex-Baillie Willox, is clearly of opinion that the blame for the Ruchill trouble does not lie so much on the shoulders of the medical men as on those of the matron

and of the convener of the Hospitals Committee. The book is, it is understood, having a large sale. The interest in the Ruchill affair is by no means dead, and periodically crops up in the town council proceedings. Thus recently quite a breeze sprung up over the fact that the actual transference of the medical superintendents from Ruchill to Belvidere was not officially communicated to the council though notified in the newspapers as having taken place. The official explanation offered was that the matter must first come before the Hospitals Committee before it could be reported to the town council. Apparently certain members are determined to lose no opportunity of bringing up all doubtful points about the hospital administration, and one member has refused to accept the rulings of the chairman, and has, in consequence, been repeatedly suspended.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LONDON.

THE PROPOSED HOSPITAL IN PUTNEY.

SINCE the Annual Representative Meeting at Sheffield, little has been heard of the Putney hospital question, but it has not been forgotten. The work involved by its existence has been quietly going on, and the matter is now ready for final consideration by medical men resident in the area likely to be affected should a hospital be brought into existence. The proposed site is Lower Putney Common (from which point are respectively distant as the crow flies the West London Hospital $1\frac{1}{2}$ miles, Bolingbroke Hospital $2\frac{1}{2}$ miles, Richmond Hospital $3\frac{1}{4}$ miles), and the affected area consists of the Putney and Southfield wards of the borough of Wandsworth and the whole of Barnes. When the proposal to build a hospital in Putney was first made—nearly three years ago—the South-West London Medical Hospital Committee was promptly formed and so constituted as to be fully representative of medical men resident in the district, whether members of the British Medical Association or otherwise. It laid down certain principles, all of which were subsequently adopted at the Sheffield meeting already mentioned. Four of them were adopted likewise by the committee of laymen formed to bring the hospital into existence. Hence, so far as general principles are concerned, all that now has to be done is to secure the establishment of the fifth axiom. This is that local medical men shall be directly and adequately represented on any committee formed either to evolve a constitution for the proposed hospital or to manage such hospital when established. The more interesting features of the plan suggested for putting the principles in question into practice are as follows: The hospital will have no out-patient department, and have no more than twenty free beds (these being as many as the funds of the hospital can support, and as many as the district is estimated to require). Cases of emergency or accident not deemed suitable for admission will be referred elsewhere for subsequent treatment; a medical certificate of suitability for admission will be an essential condition of admission, and any patient will be at liberty to be treated by his own medical man if he desires. There will be a consulting staff of six specialists, and an ordinary staff of four local medical men. The latter will remain in office for four years, but be re-eligible for a second like period. Between a second and third term there must be an interval of two years. Of the members of the governing body one-third must be local practitioners, elected by their fellows. They will retain office for five years, and be ineligible for further service until the lapse of another five. The medical governors and the local medical staff will together form a medical committee, to which all medical matters and appointments will be referable. A vote will be taken on these and other points at a meeting to be held at the house of the Putney Constitutional Club on June 3rd at 3.45 p.m. All local practitioners, as well as members of the Chelsea, Richmond, and Wandsworth Divisions of the British Medical Association, are invited to be present, and it is to be hoped that every one concerned will endeavour to be

present. No suggestion seems to be forthcoming as yet as to the way in which the first staff shall be chosen, and on this point, as also on the length of tenure of office by the medical staff and the medical governors respectively, free expression of opinion is desirable. As for the former, a period of two years, with an interval of one year before re-election, has elsewhere been found to work well, and may be thought to be more in accordance with the cottage hospital idea underlying the general scheme than a certain four years and a possible eight. The period allotted to medical governors is also important, as it is in their hands apparently that all future appointments to the staff will mainly rest. In any case all medical men resident in the area should make it their duty to attend.

TREATMENT OF RINGWORM.

A report on the treatment of school children suffering from ringworm, presented by the Education Committee at the meeting of the London County Council on May 25th, pointed out that when treatment by the ordinary means of ointment is adopted, prolonged absence from school is necessary, and there is also risk of other children being infected. Treatment by means of *x* rays, however, is effective as a rule after one exposure. The Committee proposed that the *x*-ray apparatus at the Whitechapel fairs school should be utilized for the treatment of ringworm cases. It would be possible for the school doctor to undertake the work without involving additional cost. Mr. Cyril Jackson, Chairman of the Committee, mentioned that he heard objections to this proposal on the ground that the children's heads were injuriously affected by the action of the *x* rays. Parents should know that that was not the case. He had seen the children treated at one of the hospitals. They said they felt no pain, but he understood that sometimes straight hair became curly after the application of the rays. The recommendation was approved.

DAYLIGHT SAVING BILL.

The London County Council, unlike many other responsible bodies in the country, declines to take the Daylight Savings Bill seriously. On May 25th it was invited by the Education and Highways Committees to express its approval of the measure on the ground that it would be of advantage to the education service and to the tramways—the latter, it was estimated, would benefit to the extent of £8,000 a year. An amendment was moved that the Council ought not to express an opinion on so contentious a measure. Mr. Waterlow, M.P., and Mr. Barlow appealed to members to discuss the question on its merits, but amid cries of "Waste of time" and "Vote, vote," the question was put and the amendment agreed to by 40 votes to 28.

A BAD DAY FOR THE BARNES COUNCIL.

The principal duties of a medical officer of health are set out in the order of the Local Government Board, dated March 23rd, 1891, but there are also certain statutory duties of an important character. For example, Section 30 of the Housing of the Working Classes Act, 1890, requires the medical officer of health to represent to the local authority of his district any dwelling house which appears to him to be in a state so dangerous or injurious to health as to be unfit for human habitation. Having made such representation further action falls upon the sanitary authority, and it is common knowledge that these bodies are not as a rule at all eager to give effect to the initial proceedings of their official. An instance in point has occurred in the urban district of Barnes. During several years past the medical officer of health (Dr. F. G. Crook-shank) has upon various occasions reported upon the insanitary condition of numerous houses in certain areas of the district, but, no action having been taken by the district council, an inquiry into the circumstances was recently held by an engineering inspector on behalf of the Local Government Board. The evidence laid before the inspector disclosed a very serious state of affairs, for the advocate of the council, Mr. Foote, K.C., had to admit that several of the blocks of houses in the area dealt with were unfit to live in and were injurious to health. One of the district councillors stated that the opposition to the recommendations had arisen because the medical officer of health had done his duty towards the inhabitants of the district, and he made a further statement, which does not

appear to have been disputed, namely, that at a recent meeting the council was told that the medical officer of health was taking up a position against his masters, and that it was a bad day for the council when it elected its medical officer for a period of four years instead of for one year. Can any stronger argument be brought forward in favour of the abolition of non-lapsing appointment of medical officers of health than this remark of a "responsible member of a sanitary authority?"

LEEDS.

THE GENERAL INFIRMARY.

Resignation of Mr. Edward Ward.

SOME few weeks ago Mr. Edward Ward, Senior Surgeon to the General Infirmary, sent in his resignation to the board. As has been well known to all connected with the infirmary, and to a large circle of his private and professional friends, Mr. Ward's health has been by no means good for some years, and the feeling of regret occasioned by his resignation, inevitable and general as it must of necessity be, is intensified by the fact that it has been determined by ill health. Mr. Ward, who studied at Cambridge and at Leeds, was appointed Assistant Surgeon to the infirmary in 1884, and on the resignation of Mr. Jessop in 1890 was promoted to the full staff. On the resignation of Mr. Mayo Robson he became the senior member of the acting surgical staff. By the rules of the infirmary, which include a twenty years' limit to service on the full staff, Mr. Ward's term of office would have come to an end next year, and his promotion to the consulting staff would have followed automatically. It is open to a general meeting of the governors of the infirmary, however, in the event of any member of the staff resigning before acting on the full staff for twenty years, to appoint that honorary officer a member of the consulting staff, and this has been done in the case of Mr. Ward. The resolution giving effect to this was moved by the Treasurer, Mr. Charles Lupton, at a meeting of the governors held on May 21st, and was seconded by Dr. Barrs, who spoke on behalf of the members of the honorary staff.

Appointment of Honorary Surgeon.

Consequent on the resignation of Mr. Ward a vacancy has occurred on the full staff, and at a meeting of the Special Election Committee, Mr. Walter Thompson, Senior Assistant Surgeon, was appointed to the post. The vacancy thus created on the assistant staff will be filled in due course.

POST-GRADUATE COURSE AT THE PUBLIC DISPENSARY.

THE summer term begins on Tuesday, June 8th, and consists of fifteen meetings which take place on Tuesdays and Fridays until July 27th. Dr. Wardrop Griffith will open the session with a demonstration on applied anatomy. His second demonstration will deal with irregularities of the heart. Dr. Trevelyan will lecture on glandular tuberculosis and its treatment by tuberculin, and on the paralysees of infancy and early childhood. Dr. Telling will lecture on purpura at his first meeting, and will demonstrate cases of skin disease at his second. Dr. Watson's demonstrations will be on the production of physical signs in the chest, and on serums and vaccines. Mr. Dobson will give a lecture on syphilis and epithelioma of the tongue, and Mr. Lawford Knaggs on fractures of the leg. Some illustrations of the pathology of pregnancy will be shown by Dr. Hellier. Mr. Michael Teale will give demonstrations on minor ophthalmology and otology. Mr. Sharp will lecture on adenoids, and Mr. Seaton will show various cases of surgical interest.

LIVERPOOL.

DISTRICT NURSING.

IN the proceedings of the recent conference on certain aspects of nursing there was little of direct interest to medical men, but some points in connexion with it are worth noting. It attracted much notice in Liverpool, where it was held, and it was generally referred to as the Jubilee Nursing Congress, but its main subject was not ordinary nursing but district nursing, and Liverpool was pitched upon as the place of meeting mainly because it

would appear to have been agreed to regard Liverpool as the original birthplace of district nursing. It is true that work of much the same kind was undertaken by the Society of Sisters of Charity, established by Mrs. Fry in Devonshire Square, E.C., in 1840, and that within eight years later the St. John's Sisters were also at work. Nevertheless, it seems fair on the whole to regard the work initiated by Mr. William Rathbone in Liverpool just fifty years ago as the real inception of district nursing as now understood. The earlier organizations were of a semi-religious character, while that of Mr. William Rathbone merely aimed at placing at the service of the poor, women who had received some kind of definite training in nursing duties. Once started the idea rapidly spread, and corresponding enterprises were started in Manchester in 1862, in Salford in 1864, in Leicester in 1867, in Birmingham in 1870, and in Oxford in 1879. Meanwhile, progress had been made in London, where, in addition to the two original institutions, the East London Nursing Society came into existence in 1868, the Metropolitan and National Nursing Association in 1874, and Queen Victoria's Jubilee Institute for Nurses in 1887. The Congress was attended by the Princess Louise and the Duke of Argyll, the Countess of Aberdeen, Viscount Goschen, and delegates from the Colonies and many foreign countries, and a message was received from the King and Queen Alexandra. A certain number of medical men also took part in the proceedings, either as chairmen of sections or as readers of papers, or both. Among the latter was Dr. Caton, who dealt with district nursing in connexion with maternity work; while Dr. E. W. Hope described the part which district nursing might play in the co-ordination of charitable efforts and limitation of tuberculosis. Similarly, Dr. Arthur Shadwell dealt with district nursing as a factor in social work, and Dr. Hayward dealt with the work of district nurses in connexion with school nursing. Judging from the proceedings as a whole, current opinion among nursing authorities seems to be in favour of securing a higher standard of knowledge among the women engaged by district nursing institutions than at present always exists, and of relieving the trained nurse of a part of the work which at present falls upon her by employing as sick-room helpers women not supposed to know anything about nursing, but prepared to take over domestic duties during sickness. It is a curious and possibly significant fact that, in spite of the multiplicity of papers read, the records of the proceedings seem to reveal no recognition of the fact that district nursing as at present carried on in some districts largely defeats its own object. Lack of attention to details of organization and administration gives rise to practices by nurses which make medical men less ready to avail themselves of their services than they otherwise would be.

WALES.

THE EBBW VALE DISPUTE.

THE *South Wales Daily News* of May 10th says:

By the rejection of the second ballot on the protracted dispute regarding the Ebbw Vale workmen's doctors' fund, the Cwm section of the fund have precipitated a crisis. The dispute is over the question of reinstatement of Dr. J. O'Sullivan on the staff. The Cwm section having finally decided to proceed for the recovery of the various sums of money awarded them by the county court, and for an injunction in the High Court to prevent any further deductions from wages being made towards the doctors' fund, the Ebbw Vale Company have now intimated that they will not collect and pay over any further money to the Fund Committee. A meeting of the General Committee was held at the Workmen's Hall on Saturday evening, and decided to ask Mr. Mills, the general manager of the company, to grant them an interview, and that the whole position be placed before a mass meeting of the payees on Saturday next.

In its issue of May 17th the same newspaper gives an account of a mass meeting of the payees of the Ebbw Vale Doctors' Fund held on Saturday, May 15th. Councillor John Gale, J.P., was in the chair.

Councillor Evan Davies, deputy miners' agent, said it was one of the most unfortunate disputes that Ebbw Vale men had ever been connected with. There was a tendency to blame the Doctors' Committee, but the committee was in no way responsible for the position as it was understood that day. They had

chosen the path of least resistance, and carried out to the best of their ability the desires and decisions of the general meeting of the payees. The resignation of the chairman and the retirement of the committee at a critical stage of the dispute did not help matters. Two ballots had been taken; the first was objected to as being conducted unfairly, and the decision of the other would not be accepted by the other side. The solicitors of the Cwm and Waun Lwyd section were pressing for their money for costs, etc., incurred in the County Court action, with the result that £340 had to be paid over. They were also faced with a further action in court and the possibility of an injunction in High Court. The Ebbw Vale Company did not intend going to any further expenses in law cases, and Mr. Mills suggested that the whole of the facts of the dispute should be submitted to three gentlemen who were entirely outside and independent, and he would give an undertaking that the award of that arbitration should be strictly carried out. As an alternative he would draft a scheme and submit it to both sides for their adoption or modification, and if his services were required he was quite prepared to act. Unless something was done in the immediate future the Ebbw Vale Company would have to take such action that they did not want to take—namely, to decline to make any further deductions at the office.

Mr. Chapman proposed that they revert to the old system of every man choosing his own cord irrespective of districts, with a limit to the area to be covered.

Mr. John Williams (Cwm) proposed that they submit the matter to arbitration in accordance with the suggestion of Mr. Mills. He said that both sides were anxious to preserve the fund. If it was broken up, what would become of the thousands of pounds' worth of property they possessed?

Mr. W. Hudson seconded, and an overwhelming majority declared in favour of arbitration. The secretary was instructed to write the secretary of the Cwm section asking them to agree with the suggestion, and to appoint representatives to meet to select the arbitrators.

The *South Wales Daily News* of May 19th states that the ballot of the workmen to choose their committee took place on Monday, May 17th, at Ebbw Vale. It was conducted on the new plan, that of districts, not by the different trade unions. Mr. T. Rees, secretary of the fund, acted as returning officer. The result of the election was as follows:

Ebbw Vale Miners (three seats)—John Gale, 336; J. Barber, 327; W. Hudson, 321.
Ebbw Vale Outside Men—Returned unopposed: David Evans, Henry Bowen, George Morgan, T. Llewellyn, D. Thomas, and J. Price.
Victoria Miners (one seat)—Henry Carter, 55.
Victoria Outside Men (one seat)—A. Price, 105.
General Office—Mr. Edward Watkins, unopposed.
Waun Lwyd Miners (one seat)—W. Brewer, 65.
Waun Lwyd Outside Men (one seat)—T. Lewis, 90.
Wm Miners (two seats)—J. Morgan, 182; John Morgan Williams, 134.
Beaufort Miners (two seats)—J. Phillips, 130; J. Evans, 124.
Brynmaur (one seat)—J. Huish, 118.
Srhynow (one seat)—W. Rudman, 28.

The polling was rather weak, especially in the lower part of the district.

India.

THE KASALI INSTITUTE.

THE seventh annual report of the Pasteur Institute at Kasauli, unlike its predecessors, covers the work of one complete calendar year—January 1st to December 31st, 1907. In this year the number of patients showed a further increase, in spite of the opening of a second institute at Coonoor. Altogether 1,349 persons underwent treatment, in addition to 69 who applied for advice, but were not deemed to require injections. The classification of patients shows that all classes of Indians have equal faith in the value of the treatment. In the list of animals from which bites were received there is a curious variety. Dogs predominate, then come jackals, the remainder including one donkey, two buffalos, one bear, and four bites by men. The dates at which the patients arrived for treatment indicate no seasonal prevalence of rabies in animals. As in previous reports, the cases are further classified according to the situation of the wounds and according to whether or not the animal was definitely proved to have had rabies. The percentage of failures among all classes was the lowest yet recorded—namely, 0.44, or six failures in all. Five of the six failures were in persons bitten on the bare skin, the sixth person being one who was wearing very thin clothing and received four deep

bites. In three of these cases other persons had been bitten by the same animal, and had been treated in the institute and recovered. The interval elapsing between the time of bite and commencement of treatment in these failures varied from four to twenty-four days. One of the two European cases is somewhat curious, for the disease did not develop until seven months after the cessation of treatment. During the year the technique elaborated by Pasteur was abandoned for the dilution method suggested by Høyes of Budapest, and the results thus obtained are deemed to have been greatly superior. Apart from giving a lower percentage of failures, it has the advantage of simplicity and accuracy. In the old method patients were injected with emulsions of cord, the virulence of which had been reduced by drying to the strength regarded as necessary in each individual patient. In the new method a small piece of the central nervous system of fixed virus is weighed and emulsified, and then reduced to the desired strength by diluting with salt solution. The amount of injection which has to be used is much smaller than formerly, and instead of a constant supply of large numbers of rabbits being required only one day is necessary, however great the number of patients. Hence a good deal of expense and an immense amount of work in the inoculation and dissection of rabbits and the drying of cords is dispensed with. Furthermore, uniformity and accuracy of dosage is secured and injection into the patient's system of substances other than the desired amount of toxic material is reduced to a minimum. Hence unfavourable reactions, including paralyses, which are not uncommonly noted when dried cord is used and which are due to what was regarded as inseparable organic material, can now be avoided.

BERLIN.

Tuberculosis: Notification and Disinfection.—Statistics of Appendicitis.—Orientation of Schools.

THE German Central Committee on the fight against tuberculosis held its annual congress in the Parliament Hall of the German Reichstag during the recent parliamentary recess. Secretary of State Herr v. Behrmann-Hollweg presided, and there was the usual corona of Government and civic delegates and of distinguished specialists, among the latter Robert Koch. In a paper on "Disinfection in Tuberculosis," Kirstein (Stettin) spoke on the uncertain results obtained by sputum disinfection with chemicals (lysoform, formaldehyde, carbolic acid, antan, etc.), and expressed his conviction that the most thorough and most practical means of getting rid of the sputum was to collect it and pass it down the drainage pipes, where it was rendered quite innocuous through the enormous dilution it underwent. With regard to disinfection of dwellings, Kirstein pleaded for stringent legislation which should enforce disinfection after the removal of tuberculous persons and before new tenants be permitted to take possession. He recommended that notification of every case of tuberculosis should be compulsory, and that the landlord should be liable for proper disinfection of every dwelling vacated by a tuberculous person. This, Kirstein insisted, was the great desideratum in the struggle with the scourge. A discussion followed, animated enough, but chiefly one of ways and means, for all speakers unanimously recommended Kirstein's plan. Yet its practical difficulties are enormous, if not insuperable. In Germany removals—especially those in the lower class of small flats and tenement dwellings—take place almost exclusively on the quarter days. Even assuming that disinfecting experts would be available in sufficient numbers on these days, how could the work be done quickly enough even in the smallest decent homes—the "two rooms and kitchen" of the German workman? Are the new tenants to stand outside in the street, their bits of furniture exposed to the weather, while disinfection goes on within? And will not landlords fight shy of letting dwellings to tuberculous persons who are forced to put up with the worst class of—that is, the most unhygienic—dwellings?—an effect surely the opposite of that desired and aimed at.

The general inquiry on the subject of appendicitis in Germany during the year 1907 set on foot by the Berlin Medical Society two and a half years ago is now complete, and the statistics collected were communicated by Professors Albu and Rotter to the society at its last meeting. The statistics deal with 4,800 carefully tabulated cases. Of the cases that came under medical treatment from the first day of illness, 4.1 per cent. ended fatally; of those medically treated from the second day, 4.9 per cent.; and of those not under medical care until at a later stage, 11.9 per cent.; 68 per cent. were first and 19 per cent. second attacks, the remaining 13 per cent. third (or more) attacks. Of the 4,800 cases, 1,344 came under operation, the majority being severe types. Of those operated within the first forty-eight hours, no more than 0.9 per cent. died; of those operated on the third day 7 per cent. died, the mortality figures rising considerably after longer intervals. As regards sex of the cases, males were in the majority by about 10 per cent. Children gave the highest proportion of fatal endings, probably because children in general fail to give a clear account of their symptoms.

In a paper on heating and ventilation of schools, read before the German Society for Public Hygiene, Dr. A. Marx gave an account of a real set of botanical experiments, which prove by analogy how all-important sunlight is for the development of the human organism: cultures of bean-plants were made, one in ground fully exposed to direct sunlight, and the other in ground lit by diffused light only. The descendants of both cultures were then cultivated in one and the same sunny situation—with the result that, after the second generation, no fertile seeds could be obtained from the second culture. From this Dr. Marx deduces that schoolrooms should not face north. A westerly aspect he thinks the best for morning-hour schoolrooms.

Correspondence.

SPIRITUAL HEALING.

SIR,—In the article which appeared in the last number of the JOURNAL on the above subject you allude to the difficulties which exist in attempting to verify the correctness of the diagnosis in cases of asserted cures. The following case, which occurred in my own practice, is an instance of how little credit many of these statements are worthy of.

Shortly after I retired from practice some ten years ago, a well-known clergyman wrote to me saying that members of his congregation were being much disturbed by the advent amongst them of a lady professing herself to be a faith healer, and saying that her conversion was due to the fact of my having told her that she was suffering from a dreadful disease and that her sole hope of cure lay in the performance of a very dangerous operation. She refused to submit to this, and instead placed herself in the hands of the "healers" and was cured. He concluded by asking me to give him particulars of her case.

I had no recollection of any such patient, but as the name was given, traced her and found the following particulars recorded in my casebook:

I had only seen the lady once in my own house, when she had stated that she was well past middle life, and for more than a year had been weakened by the frequent recurrence of very profuse menstruations, the loss being sometimes quite alarming.

On my telling her I must examine her she had replied that she could not submit to it that day, as the discharge was then heavy, so I arranged that when it had ceased she would let me know, and I would call on her and examine her in bed. I made no diagnosis and gave no opinion as to the nature of her case. No doubt I may have told her that such symptoms often indicated serious disease, but to talk of performing an operation on a patient I had never examined, I never would have done, nor any other sane practitioner.

Instead of writing to me to call on her, she went to London. No doubt an examination would have revealed the fact that no disease existed.

It is impossible to deal with patients of this class. Their mental equilibrium is disturbed, they distort what

the doctor may say, and not infrequently invent and circulate statements he never made.—I am, etc.,

Dublin, May 24th.

LOMBE ATTHILL, M.D.

MYASTHENIA AND HYPOPHYSIAL LESIONS.

SIR,—Your readers will be interested to hear that in the BRITISH MEDICAL JOURNAL, vol. i, 1867, pp. 597–600, a case was described, under the title of "Case of Paralysis of the Diaphragm, with Remarks," by the late Dr. P. Victor Bazire, that was almost certainly one of myasthenia. Bazire was on the staff of the National Hospital for the Paralysed, London, and he died suddenly in August, 1867, three months after the case was published, but the sequel was never recorded apparently. That he was an exceptionally able man will be seen on reference to the obituary notices in (a) BRITISH MEDICAL JOURNAL, vol. ii, 1867, p. 141, and (b) *Lancet*, vol. ii, 1867.

It will be remembered that Dr. Leonard Guthrie mentioned in the *Lancet*, vol. i, 1903, p. 330, that the famous Dr. Willis had published a case in 1685 that seems to show that the disease was known to him then. Dr. Guthrie points out that Willis evidently regarded his case as functional. I shall show that Bazire did not fall into that error over his case.

Bazire's Case of Myasthenia (italics mine, unless otherwise stated).—"F., 41, married; tall, thin, bony, pale, sallow. Previous history good: nervous and excitable, easily moved, subject to depression of spirits; no history of hysterical fits, crying or sobbing; has been working hard and living poorly of late. Her son, aged 14, epileptic (under B's care). Present condition: Fifteen months ago gradual onset of epigastric discomfort (weight, not pain), and difficulty of breathing: kept gasping to take in more air. These sensations came on towards evening, most marked when working hard, washing or ironing. With the difficulty of breathing came loss of voice: Frequently towards evening she would lose her voice completely, and speak in whisper. If, however, she did during the day only sewing, etc., no dyspnoea occurred, and her voice was louder. She was always better in the morning; if she had gone to bed voiceless overnight she would wake up after a good night's rest perfectly able to speak. No cough: no pain in chest, no soreness, no abnormal sensations in throat to which she might refer her occasional and intermittent aphonia."

Bazire goes on, p. 597, col. 2: "When I first saw her, the peculiar character of her voice attracted my attention at once." He compares her to a person out of breath from running, but notes that: "Instead of her voice improving, as she went on talking, it became weaker and weaker, occasionally squeaky, till at last it left her completely, and she could not for a while proceed even in a whisper. This statement was confirmed by the nurse after the patient's admission to the hospital" (p. 598, col. 2).

Bazire found nothing in throat: cords came together perfectly on phonation. R. 32: breathing costal; on deep inspiration epigastrium was observed to sink inwards (italics in original); during expiration the parts that had sunk in during inspiration bulged outwards (italics in original); no lividity of lips or face; good entry of air in lungs: normal percussion. Heart regular; impulse somewhat feeble; sounds not very loud, but normal at apex and base. P. 65, regular. No enlarged glands at root of neck, nor any signs of aneurysm.

The paper is a very interesting one. As to diagnosis, Bazire held that the feebleness of the diaphragmatic action, on galvanization of the region of the phrenic in the neck, which he found "pointed to structural disorganization of the muscle." This proves that he rejected hysteria as a diagnosis. There is no mention of faradism; but we know that the myasthenic reaction is not always present in myasthenia.

Evidently Bazire recognized the intermittent aphonia brought on by exertion and relieved by rest as something quite new to him—and he was a very learned physician. The myasthenic nature is obvious.

Dr. E. B. Krummbaar has recently mentioned (*Bull. Ager. Clin. Labor., Pennsylv. Hosp.*, No. 5, December, 1908, pp. 32–45) that as far back as 1679 Theophilus Bonetus described what was evidently a serous cyst of the hypophysis (*Sepulchretum sive Anal. Practica*, Geneva, 1700, p. 24, obs. 24). Krummbaar quotes thus:

§1. Capitis dolor ab abscessu seroso, natus cerebri et infundibulo adherente. A girl, 12, phlegmatic and dull temperament, suffered for four months with a severe, continuous headache. When called to her case, I found her quite without fever, but rejecting all food. She lived for many days on sugared water only. She complained of pain over the coronal sutures. All remedies were vain; no swelling or redness was present; finally death put an end to her miseries and pain. On opening the head, everything was found beyond expectation well formed and without corruption. I had expected to find pus, as a little before death the right eye had

emitted some purulent fluid. But, when we despaired of ascertaining the cause, the surgeon, wishing to demonstrate to his pupils the rete mirabile and other parts, broke with his fingers an abscess which was adherent to the folds and infundibulum of the cerebrum, from which clear water flowed with force to the extent of 2 lb., as if gushing from a fountain.

Krumbhaar comments thus (page 41):

The enormous cyst, the modern equivalent of serous abscess, if attached to the infundibulum, evidently arose in the hypophysis. The dull phlegmatic temperament is interesting as a possible evidence of myxoedema, which has been found to have some connexion with lesions of the hypophysis.

In conclusion, Dr. F. Tilney has recorded a case of typical myasthenia¹ in which autopsy showed an adenoma of the hypophysis, originating in its anterior lobe and almost completely disintegrating its posterior lobe. I am told by a friend that he thinks one or two similar cases have been recorded, but at present I have failed to find them.

To sum up: Bazire's case is, with the single exception of Willis's, the most ancient case of myasthenia yet discovered; his description is far fuller than that of Willis's, and his greatness is shown by his rejection of the diagnosis of hysteria. It is of great interest after studying Bazire's case to refer to some excellent remarks on the differentiation between hysterical and myasthenic dyspnoea in a paper by Dr. Guthrie in the *Lancet*, vol. i, 1901, p. 395.—I am, etc.,

London, W., May 24th.

LEONARD J. KIDD.

FOREIGN BODY IN THE AIR PASSAGES.

SIR,—The letter by Dr. William Hill (p. 1268) with reference to the case published in the *JOURNAL* of May 15th, p. 1180, seems to me very opportune, and, like him, I desire to emphasize "the value of the bronchoscope in the investigation of cases of limited bronchiectasis of obscure non-tuberculous origin."

The details of the case published by Mr. Stroud-Hosford would suggest that, even had the foreign body been detected and removed when the patient was first admitted to the hospital, a fatal issue might only have been delayed. On the other hand, the history of such a case teaches two important lessons:

1. The value of skiagraphic examination in each and every case of limited bronchiectasis in children as well as in adults. Perhaps it would not be going too far to insist on the value of this mode of examination in any case presenting anomalous chest symptoms. In this particular instance the presence of the tintack would certainly have been revealed.

2. The great value of the bronchoscope in the examination and treatment of such cases. In this particular patient it is almost certain that the tack could have been removed by any one reasonably familiar with and skilled in the use of the instrument, although it is doubtful whether this would have saved this patient's life, because of the advanced stage of the lung mischief.

It has been my privilege to remove a large pin and the metal cap of a lead pencil from the larger bronchial tubes of two young patients, and during the past six years to make many examinations of the lower air passages by the direct method, and I do not think it an exaggeration to say that the method only needs a little skill, patience, and attention to technique.

Readers who are interested in the construction and uses of the bronchoscope will find an illustrated article dealing with the subject in the *Lancet*, November 7th, 1908, or in the *Laryngoscope*, December, 1906; and I am glad to think that since the publication of the first named the use of the bronchoscope has become much more general in this country than was hitherto the case.

It is only fair to state that for the perfection of the modern instruments we are indebted to Killian and Brining of Freiburg and Chevalier Jackson of Pittsburg, Pa.—I am, etc.,

London, W., May 23rd.

HERBERT TILLEY.

SIR,—The question raised by Dr. Hill is worthy of serious consideration, and his plea for a more extended use of the bronchoscope in affections of the chest comes at an opportune time, and deserves support. To those who are accustomed to make use of it in their daily work it appears surprising that those who devote special study

to chest diseases should have hitherto failed to appreciate its advantages.

An endoscopic view of the interior of a bronchus affords much more information than an indirect examination however carefully carried out. In many conditions which are obscure and puzzling to the observer, a correct diagnosis is only possible with its aid. I have already drawn attention in the *JOURNAL*¹ to some of these, and subsequent experience has fully confirmed the views I have there expressed. I make regular use of bronchoscopy in the investigation of affections of the bronchi. It can be carried out with safety, and one might quote instances of the invaluable help which a direct view of the interior of the bronchus has given, were there space to do so. One will suffice, that of a patient who had been under treatment for some time for "bronchitis and asthma." It was only on making a bronchoscopic examination that a benign growth, quite unsuspected, was discovered just above the bifurcation of the trachea. Its removal led to entire disappearance of the symptoms.

To those who may be sceptical of the feasibility of applying direct methods to intrabronchial conditions a case recently recorded by Killian² is worth mentioning. A man had a carpet tack embedded, head downwards, in the right bronchus. Its presence had led to marked stenosis and bronchiectasis. After repeated attempts the stricture was dilated and the foreign body extracted. The constricted bronchus was afterwards intubated, the tube being changed from time to time, and this was followed by a corresponding improvement in the chest condition. Yet that patient had suffered from chest trouble for over five years, and had been treated in various sanatoriums until a skiagraph revealed the presence of the foreign body, which had never been suspected.—I am, etc.,

Cardiff, May 24th.

D. R. PATERSON.

SIR,—The sincere thanks of all clinicians are due to Dr. Murray Leslie for his public spirit in placing on record the above case which affords several lessons.

Rightly or wrongly, some of us think that no value whatever is to be placed on a negative history as to ingestion of a foreign body in a child of this age, and the result in this case confirms our view.

Further, many of us regard it as an axiom in physical diagnosis that in one-sided lung disease with copious foul expectoration (more especially if there are signs of a cavity), the presence of a foreign body in a bronchus or bronchiole should be suspected, and its presence or absence proved by every means available, that is, radiology and bronchoscopy.

I have no doubt Dr. Murray Leslie used all the thoroughness and care for which he is so well known, and from the positive physical signs *plus* the negative history, was convinced that he could exclude the hypothesis of foreign body in favour of idiopathic disease. That he has had the courage to acknowledge that his conclusions in this case were incorrect, and to give full details of the ultimate result is likely to be of special interest and benefit to the profession now that the direct examination and treatment of the air passages, after having been a series of surgical triumphs on the Continent and America for some years, is at last becoming one of the burning medical questions of the day in these happy isles.

These cases are, after all, not very common, and since Killian's first case in 1897, there have been only about 200 recorded, according to the latest statistics in my possession (up to 1907).

Evacuation of the putrid contents of any accessible pulmonary cavity, and irrigation and perhaps drainage by pneumotomy, cutting down on the tube introduced into the cavity *per vias naturales*, is to be advised. Perhaps the utility of this letter will be increased if I just mention some of the chief conditions in which bronchoscopy has given the greatest assistance either in diagnosis or treatment: Tracheitis, tracheal papillomata, tracheal and bronchial ulceration and stenosis, adherent diptherial membranes, inspissated secretions and crusts in trachea and bronchi, and oesophageal growths, aneurysm, thyroid and thymus tumours as causes of dyspnoea from pressure on trachea. A recent case has been reported in which a diagnosis of dilatation of the aorta has been proved by

¹ BRITISH MEDICAL JOURNAL, 1906, vol. ii, p. 356.

² *Zeitschrift für Ohrenheilkunde*, Bd. 55.

¹ *Neurographs*, vol. i, No. 1, March, 1907.

tracheoscopy, and in which there were no other physical signs. The range of bronchoscopic possibilities is hence very great. The technique is to be acquired without any extraordinary difficulty, and so much experience has been accumulated, that the procedure with care is quite safe.—I am, etc.,

London, May 23rd.

ROBT. HY. SCANES-SPICER.

SIR,—I have read with interest the letter of Dr. William Hill, urging the importance of a bronchoscopic examination in cases of bronchiectasis, in which there is no obvious pathological cause such as tuberculosis, which would render the examination unnecessary. I would like to endorse fully Dr. Hill's remarks from my clinical experience of cases of this kind. Last year a case was under my care at the Great Northern Central Hospital, the patient being admitted with symptoms of pneumonia. Bronchiectasis at the right base was diagnosed, and this was complicated by septic pneumonia of the right lung. The ordinary methods of examination failed to reveal the presence of any foreign body, but at the necropsy a piece of bone was found lodged in the right bronchus which had given rise to all the symptoms. Had this patient been examined by the bronchoscope in the early stages of her illness I think the foreign body would have been seen, and could have been removed. I can recall other similar cases to that described. Since the prognosis in cases of this kind is extremely bad, septic pneumonia being almost certain to supervene if the case is left, in my opinion the bronchoscopic examination should always be resorted to early, so that the actual cause of the condition may be diagnosed, and if possible removed.—I am, etc.,

London, W. May 23rd.

W. H. WILLCOX, M.D.

SIR,—Dr. William Hill aptly points the moral of Dr. Murray Leslie's interesting case of foreign body in the air passages recorded in the JOURNAL of May 15th. It is a good example of the value to medical science which may accrue from the publication of our unsuccessful results. It cannot be too widely known that direct bronchoscopic examination is no longer a difficult procedure, and that it is likely to afford a most valuable method of investigation in obscure cases of pulmonary disease. Although in this case the disease was so advanced when the child came into the hospital that it was extremely doubtful if removal of the body would have effected a cure, yet the child had suffered from pulmonary symptoms for a considerable time, and, as the tack was situated in the left bronchus only 1 in. below the bifurcation of the trachea, there would probably have been little difficulty in recognizing and removing it.

I agree with Mr. Hill that this method should be employed even in cases in which no history pointing to foreign body can be obtained, for it is well known that such a history is often absent, and in cases in which an x-ray examination is negative, for the body may not be opaque, and I join with him in expecting that a routine bronchoscopic examination will in the near future take a recognized place in the diagnosis and treatment of such conditions as localized bronchiectasis.—I am, etc.,

London, W. May 25th.

HAROLD BARWELL.

SIR,—Without referring in any way to the case reported by Dr. Murray Leslie in the JOURNAL of May 15th, I should like to emphasize the value of direct vision laryngoscopy and tracheo-bronchoscopy, as described by Dr. W. Hill. After the meeting of the Balmatological and Climatological Society a fortnight ago, Dr. Hill gave a demonstration at the Torbay Hospital, and the ease with which it was possible to see into either bronchus or to the entrance of the oesophagus into the stomach was a revelation to most of those present. I therefore most heartily endorse all that Dr. Hill has said in his letter as to the value of this method of investigation, and am quite sure that examinations and operations are now rendered possible which were impossible by the ordinary method.—I am, etc.,

Torquay, May 26th.

WILLIAM ODELL.

TETANUS OCCURRING AFTER SURGICAL OPERATIONS.

SIR,—With reference to the paper published by Mr. W. G. Richardson in the JOURNAL for April 17th last, I beg to enclose notes of a case which has occurred in my practice:

A. T., male, aged 47 years, was admitted to the Kidderminster Infirmary on January 18th, suffering from extensive varicose veins of both lower extremities. He had been operated upon previously without benefit. An operation was performed on January 22nd. Five incisions were made on the left and three on the right side, varying in length from 2 in. to 4 in. The vessels were ligatured with catgut and the wounds closed with silk-worm gut. They were dressed on January 29th, when all were found to have healed per primam, and the sutures were removed. Two days later he was allowed upon the couch. His general condition was quite satisfactory.

On February 7th he was found to be suffering from well-marked symptoms of tetanus, rigidity of the muscles of the neck, and trismus, and he died the same evening, in spite of treatment, including injections of antitoxin, etc.

This is the only case of tetanus following a surgical operation in my practice, which extends over nearly thirty years. I was naturally much concerned, and in endeavouring to account for it I considered the many possible sources of infection. The catgut I use is prepared according to the directions of Sir William Macewen. It is stored in large glass jars. The one from which this gut was taken is in constant use, and I cannot help thinking that I should have had other cases if this was the source of the infection.

From my experience of tetanus, most of the cases occur in those who are associated with horses. This man had been a shoeing smith, and although he had not followed his occupation for two or three years I think it is possible that a bacillus managed to secrete itself about him, and was introduced by scratching, which we found he had indulged in.

I quite agree with Mr. Richardson that the importance of acquiring catgut is of great moment, but I am inclined to wait until the case against it is absolutely proved before relinquishing its use.—I am, etc.,

J. LIONEL STRETTON,

Senior Surgeon to the Kidderminster Infirmary and Children's Hospital.

Kidderminster, May 24th.

COAGULATION TIME OF THE BLOOD.

SIR,—Kindly allow me a last word with regard to Dr. McGowan's letter in your issue of May 15th.

No doubt it is perfectly excusable for Dr. McGowan not to know of my existence, but scientifically it is not excusable for him to establish a method without taking the elementary precaution of finding out what work of a similar nature has previously been done on the subject.

A description of my method appeared not only in an international journal of haematology (*Folia Haematologica*), but it can also be found in the textbook of Gravitz.

I agree with Dr. Addis that in the immense majority of cases the first drop of blood obtained coagulates later than the following drops, and this fact was also pointed out by Milfan several years ago.

It is for this reason, as I stated in my first letter, that I use the second drop as the one which indicates the coagulation time; the other drops being only employed as indicators.

Further, owing to the sensitiveness of the clotting time to disturbances, I would again insist on the importance of using tubes with an internal diameter of not more than 1 mm., because in larger tubes the fine filament of fibrin is pulled out with greater difficulty, or may even be lost sight of.—I am, etc.,

Laboratoire des Cliniques, Bordeaux, May 20th.

SABRAZÈS.

P.S. (May 24th).—My first letter, which has provoked a long and interesting reply from Dr. Addis, had no other object in view than to point out that the principle of the methods described by Drs. McGowan and Addis—that is, a column of blood in a glass tube, which is kept at a constant temperature, breaking, and drawing apart the fractured ends, until a fine fibrin thread is seen—is no other than that of my method, which I first published several years previously. I still maintain this statement. As to the rest, it is a question of details of application in technique and of personal opinion, and I feel that the

subject of coagulation of the blood is too complicated to be treated "au pied levé" in a correspondence column.

ACUTE THYROIDITIS.

SIR,—In the BRITISH MEDICAL JOURNAL of May 1st, p. 1064, Staff Surgeon Kenneth Jones published an interesting and very rare case of acute thyroiditis.

Allow me to state that this case, according to the description of it, belongs to a form of acute thyroiditis described first in English literature (*Journal of Laryngology*) in 1895 by me under the term *Thyreoiditis acuta simplex*—that is, an acute inflammation of the thyroid gland, ending in resolution without forming an abscess. Later, in 1904, Dr. de Quervain of Bern wrote an essay on this form (*Die acute nicht eitrige Thyreoiditis*).—I am, etc.,

Kjøbenhavn, May 8th.

HOLGER MYGIND.

HYPODERMIC INJECTION OF STRYCHNINE.

SIR,—In the JOURNAL of May 15th, in the report of the Medical Society of London, the use of strychnine injections in the treatment of shock was condemned by two speakers—Mr. Malcolm and Mr. Keetley. The objection would, I presume, equally apply to collapse from hæmorrhage or occurring during the course of acute disease. Now, like, I suppose, nearly every other general practitioner, I have for some years been using strychnine in these anxious emergencies. Some have recovered and some have died, but not in one single case have I been able to satisfy myself that the treatment did any good at all, or that any of these patients were in any way stimulated by the remedy. It is the fashion to use strychnine in all cases of collapse from whatever cause arising. It finds a place in the midwifery bag, and the nurse from the institute brings with her a hypodermic syringe and a bottle of strychnine tablets to use should the necessity arise. It is a very handy remedy, but is it any good?

Now strychnine is not an inert drug, and used as it so often is in cases which may fairly be said to be hovering between life and death it must have a very decided influence one way or the other for weal or for woe.

It is with the hope of drawing opinions from those who have more opportunity of looking into these matters than myself that I write these few remarks.—I am, etc.,

Milverton, Somerset, May 26th.

CHARLES RANDOLPH.

THE ASSOCIATION.

SIR,—In the Council report of 1908-9 regret is expressed "that the increase in the membership has not been more marked, in view of what the Association is doing for the medical profession." How can any one, other than the Council, wonder at this?

Since the Association has been broken up into Divisions, a great amount of superfluous printed matter has been constantly sent to them—dealing with subjects in which only a very limited minority take any interest—converting the old pleasant meetings of the Branches into a humdrum ordeal, without one item to interest or amuse the younger members. Further, unless there is in each Division a very energetic secretary or some enthusiastic member, no endeavour is made to reach the junior members of the profession, and to point out to them that, besides a very excellent JOURNAL, there are many advantages in being a member of the Association. It is a primary duty of the Council to devise means to arouse more enthusiasm rather than express regrets.—I am, etc.,

Harwick, N.B., May 24th.

JOHN R. HAMILTON.

RESEARCH DEFENCE SOCIETY.

SIR,—The Committee of the Research Defence Society have asked me to send you a copy of a letter which has been sent to the Secretary of State for Home Affairs, as follows:

Research Defence Society,
70, Harley Street, W.,
May 26th, 1909.

To the Right Hon. Herbert J. Gladstone.

SIR,—We desire, as members of the Research Defence Society, to call your attention to the following facts:

The Royal Commission on Experiments on Animals was appointed in 1906. It began to hear evidence in October of that year; and during 1906 and 1907 a great amount of evidence was given by many witnesses. So long ago as December 18th, 1907, the Commissioners decided that they did not wish for any

further evidence; but they met once more, on March 25th, 1909, to hear evidence on a special point. Apart from this one meeting in 1908, it is now nearly a year and a half since the Commissioners ceased to hear evidence; but they have not yet issued their report.

We are of opinion that this long delay is contrary to the public interest, and is likely to prejudice the public mind. We, therefore, beg you to exercise all your influence to hasten the issue of the report.

We remain, Sir,

Yours faithfully,

The letter has been signed by the Earl of Cromer, President of the Society; the Hon. Sydney Holland, Chairman of Committee; the Duke of Abercorn, Lord Avebury, Lady Bliss, Lord Robert Cecil, Lord Chylesmore, Sir Savile Crossley, the Hon. Walter Guinness, Sir Edwin Ray Lankester, Sir Frank Lascelles, Mr. Frederick Macmillan, the Earl of Malmesbury, Sir Patrick Manson, the Duke of Montrose, the Dean of St. Patrick's, Lord Rothschild, Mrs. Scharlieb, Professor Starling, Sir Reginald Talbot, Sir Frederick Treves, the Duke of Wellington, and the Bishop of Winchester.—I am, etc.,

STEPHEN PAGET,

Honorary Secretary.

London, W., May 26th.

Medico-Legal.

STATUS LYPHATICUS.

AT an inquiry in Chelsea on May 1st into the circumstances attending the death at Brompton Hospital of a boy aged 14, Dr. Spilsbury, of St. Mary's Hospital, stated that the immediate cause of death was syncope, brought about by the action of chloroform in a person suffering from status lymphaticus. The deceased had an enlarged thymus gland, and the heart was fatty, but there was no valvular disease. Death occurred before the commencement of the operation, and in spite of artificial respiration. The boy had chorea at the age of 7. It was stated by the mother that he had undergone ten previous operations for nasal trouble, but what anæsthetic was used seems to be uncertain. At Brompton Hospital chloroform was selected because the boy expressed a dislike for ether.

WORKMEN'S COMPENSATION.

Termination of an Award.

IN a case heard at Leeds on May 4th, the employers applied for an order terminating weekly payments on the ground that the applicant was fit to resume work. It appeared that he suffered an injury to his back in October, 1907. He then left work for some weeks, during which he was paid 18s. a week (half wages). He subsequently gave up work on the ground that the injury prevented his doing it; and in October, 1908, the county court judge made an award in his favour of 18s. a week. The ground of the present application was that he was quite fit to resume work. Dr. Barrs, Dr. Maxwell Telling, and Dr. Lister all gave evidence to this effect. Dr. Shephard, Dr. J. Taylor, and Dr. Towers, who were called on behalf of the workman, said that they were of opinion that he still suffered pain over the seat of the original injury, but they thought that he might go back to his work. The employers, however, refused to take him back. Judge Greenhow came to the conclusion that the man was cured, and terminated the compensation altogether.

Lead Poisoning.

IN cases which involve questions relating to industrial disease, the county court judges appear to rely more and more on the assistance of medical referees. In a case heard by Judge Ruegg at Burslem, compensation was claimed by the widow of a man who worked in an earthenware factory. Death was alleged to have been due to lead poisoning. Owing to a conflict of medical evidence his Honour sent the notes of the evidence to Dr. Kaufman, who reported that in his opinion the workman had died from acute inflammation of the kidneys, and that this acute nephritis was caused by lead. Upon this an award was made in favour of the applicant.

Injury to an Eye.

IN a case before Judge Ruegg at Stoke it appeared that the applicant, who suffered from a slight squint, met with an accident in which he received a blow on the head. He subsequently became totally blind of one eye, and an operation failed to restore the sight. Two doctors stated that the condition of the eye was consistent with the view that it was caused by the blow received. Two doctors called on the part of the employers said that in their view the accident had nothing to do with the injury, the eye having been defective before. The operation had been performed with a view to improving the sight. The applicant had been given a pair of spectacles which he had refused to use. The judge accepted the applicant's story. It was possible, he said, that a man's sight might be defective without him being aware of the fact, but such a possibility was remote and had not been proved in this case.

MEDICAL WITNESSES: A HARD CASE.

ROSACEAE writes that he has arranged with a locumtenent and booked rooms for himself and family at a watering place for the first fortnight in June. He has since been served with a subpoena to attend the county court as a witness on June 9th. (1) Is he compelled to attend the county court? (2) Can he claim hotel expenses, as he would have to stay the night? (3) Is he entitled to travel first-class?

. (1) He is bound to attend on his subpoena. (2) In the county court the expenses allowed to a medical witness are from 10s. to 20s. a day, and for travelling a sum reasonably paid for such purpose, but it must not be more than 6d. a mile one way. This is usually reckoned from his residence, and it is doubtful whether it could be claimed from a locality to which the medical man had gone for his holiday.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

A COMPLICATED CASE.

TRIO writes: A., B., and C. are independent medical practitioners in the same neighbourhood. A. went away for three weeks, leaving B. in charge of his cases. The patient whom he was engaged to attend in a confinement refused to accept B., and engaged C. Six weeks before her confinement she underwent a small operation, which was performed by C., with B.'s assistance. A fortnight later C. fell ill, and B. carried on the treatment for a fortnight. C. then resumed attendance. When the confinement came on, C. was ill, and B. attended until the return of A., who then resumed the care of his patient. He asks what would be a fair way of distributing the fees.

. As the patient declined to accept A.'s substitute and B.'s relation to the case was purely as a substitute for, or as assisting C., A. has strictly no claim to any share of the fees. B. is entitled to half the fee for the confinement, such fee as may be usual for the assistance rendered by him at the operation, and half the fee for the fortnight during which he attended, C. taking the balance. If, however, C. chooses to regard himself as having acted as A.'s substitute, he would get only half the fee for the operation, half the fees for the time he attended, and B. would get half the fee for the confinement, the customary fee for rendering assistance at the operation, and half the fees for the fortnight during which he attended and dressed the case, while A. would retain the balance.

ATTENDANCE AFTER INJURY INFLICTED BY UNQUALIFIED DENTIST.

LODGE SURGEON asks a question regarding the granting of a sick certificate to a member of the lodge to which he is medical officer under the following circumstances: M., a member of the lodge, is advised by his medical adviser—we do not gather from our correspondent's letter whether he is the medical man who advised M.—to have all his teeth extracted. Some friends recommend M. to employ a certain dentist who comes to the town once a week. This M. does; the dentist injects a local anæsthetic—presumably cocaine—into the gums and extracts all the teeth. Two days after the lodge surgeon is consulted and finds M. is suffering from (1) an overdose of cocaine; (2) alveoli torn away round the teeth, gums lacerated; and (3) mouth badly inflamed and gangrenous. The lodge surgeon finds out that the dentist M. employed is unqualified. While agreeing that M. is unfit for work and must remain indoors, the lodge surgeon does not consider that M. can claim sick allowance from his lodge, as in his opinion the injured mouth is due to the careless extraction of teeth by the unqualified practitioner, and that his claim in law is against the dentist. The lodge surgeon also considers that by signing a sick certificate granting such sick allowance he would be implicating himself as covering and condoning an unqualified dentist and render himself liable under the Medical Acts. The question therefore that lodge surgeon asks is this: Can he sign a sick certificate for M. and not render himself liable in any way under the Medical Acts?

. We consider he should sign M.'s sick certificate. M., as many others do, went to this dentist presumably in the full belief that he was a fully-qualified dental practitioner. Unfortunately for M. he has suffered the penalty for doing so, and has been compelled to call in the services of the lodge surgeon, who, clearly, in our opinion, should attend M. until the condition of his mouth is such that he is able to resume work, at the same time granting the necessary sick certificates as long as they are required. We do not see how, under any circumstances, the lodge surgeon would be held as con-

doning or covering this unqualified dentist; he is called to attend M. in his capacity as lodge surgeon for an accident for which, although due to the want of skill on the part of the unqualified dentist, M. is not to blame. M., as already pointed out, went to this man in the belief that he was qualified to extract teeth in a skilful manner. The remedy M. has, as our correspondent has already pointed out, is in a court of law, where he will, judging from cases which have appeared in court lately, probably obtain substantial damages. With reference to this we would point out that if M. takes the case to a court and he is denied medical advice at this time, his case against the dentist would be very materially weakened. We are further of opinion that M. can demand professional attendance from the lodge surgeon, as, under agreement, M. pays so much a week or month, as the case may be, for the services of the lodge surgeon.

The Services.

ROYAL ARMY MEDICAL CORPS (TERRITORIAL).

HONORARY COLONELS.

DIOPHONES writes to suggest that some of the senior retired officers of the Army Medical Staff be appointed honorary colonels of medical units of the Territorial Army. Up to the present only one such retired officer has been so appointed. There are very few positions connected with the army open to army medical retired officers, and they differ in that respect from combatant officers, many of whom are appointed honorary colonels; but the reorganization of the Territorial Forces affords some opportunity to place retired medical officers on the same footing as combatant officers. Surely men who have passed the best years of their lives in the army are entitled to consideration in bestowing those honorary appointments.

Universities and Colleges.

THE NATIONAL UNIVERSITY OF IRELAND.

THE Dublin Commissioners appointed under the Irish Universities Act, 1908, to make statutes for the general government of the National University of Ireland, have just issued the statute, comprising 57 chapters.

Registrar.

The salary of the first Registrar shall be £1,000; of his successors £500, rising £25 annually to £700.

Terms.

The terms shall be known as the Michaelmas, the Hilary, and the Trinity.

Matriculation.

The subjects of study for matriculation shall be proposed by the General Board of Studies, submitted to the Academic Council of each constituent college, and prescribed by the Senate after consideration of the General Board of Studies and the Academic Council of any constituent college.

Degrees.

1. The university may confer the following degrees upon students under conditions laid down in the statutes and regulations.

A.—In the Faculty of Arts.

Bachelor of Arts (B.A.).
Bachelor of Music (B.Mus.).
Master of Arts (M.A.).
Doctor of Literature (D.Litt.).
Doctor of Music (D.Mus.).

B.—In the Faculty of Philosophy and Sociology.
Doctor of Philosophy (D.Phil.).

C.—In the Faculty of Celtic Studies.

Master of Celtic Studies (M.Lit.Celt.).
Doctor of Celtic Studies (D.Litt.Celt.).

D.—In the Faculty of Science.

Bachelor of Science (B.Sc.).
Bachelor of Agricultural Science (B.Agr.Sc.).
Master of Science (M.Sc.).
Master of Agricultural Science (M.Agr.Sc.).
Doctor of Science (D.Sc.).

E.—In the Faculty of Law.

Bachelor of Laws (LL.B.).
Doctor of Laws (LL.D.).

F.—In the Faculty of Medicine.

Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.),
Bachelor of Obstetrics (B.A.O.).
Bachelor of Science, Public Health (B.Sc., Public Health).
Master of Surgery (M.Ch.).
Master of Obstetrics (M.A.O.).
Doctor of Medicine (M.D.).
Doctor of Science, Public Health (D.Sc., Public Health).
Bachelor of Dental Surgery (B.D.S.).
Master of Dental Surgery (M.D.S.).

G.—In the Faculty of Engineering.
 Bachelor of Engineering (B.E.).
 Bachelor of Architecture (B.Arch.).
 Master of Engineering (M.E.).
 Master of Architecture (M.Arch.).

H.—In the Faculty of Commerce.
 Bachelor of Commerce (B.Comm.).
 Master of Commerce (M.Comm.).

The statute sets out the conditions on which the degrees shall be conferred in the several faculties.

The University College, Dublin.

It is provided that this College shall have a President, who shall hold office until he shall have attained the age of 70. The stipend shall be £1,500 a year, but until an official residence, fuel, and light have been provided he shall be entitled to an annual sum of £500 in lieu thereof.

The Academic Council.

There shall be an Academic Council, which shall consist of the President and Professors of the College, with such Lecturers of the College as may be co-opted by the President and Professors.

The Faculties.

The Professors and Lecturers within the College shall be constituted into the following Faculties:

Arts, Philosophy and Sociology, Celtic Studies, Science—including Technology and Agriculture, Law, Medicine, Engineering and Architecture, Commerce.

The Stipends.

In Greek and Latin the Professors shall receive £600 and £700; in modern Irish, £600; in early Irish, £600; in anatomy, £200; in experimental physics, £800; in medicine, £250; in midwifery, £200; in surgery, £500; in French and romance philology, £500.

Officers of Residence.

The governing body shall appoint two or more deans of residence and one or more lady superintendents, hereinafter called "officers of residence," and shall require every student to enter under such one of these officers of residence, subject to the direction of his parents or guardians, as he may choose.

University College, Cork.

The statute for the University College, Cork, follows the same lines as that for the University College, Dublin, with the addition of chapters on pensions, the museums, and saving of rights and privileges.

The stipend of the President shall be £1,200 a year, and he shall in addition be entitled to residence, fuel, and light.

Amongst the stipends allocated to the professorships and lectureships are the following:

Professorships.

*Physics	£600	Surgery	£250
Zoology	550	Therapeutics	100
*Anatomy	600	Hygiene	50
Medicine	200	Materia Medica	50
Obstetrics and Gynaecology	200	Medical Jurisprudence	50
*Pathology	500	Mental Diseases	50
*Physiology	500	Ophthalmology	50

Lectureships.

*Physics	£300	Dental Mechanics	£50
*Botany	350	Dental Surgery	50
Ophthalmology	50		

* Full-time appointments.

University College, Galway.

The President shall receive a stipend of £800, with residence, fuel, and light. The professorships are about the same as in Cork. The stipends are appended:

Professorships.

*Physics	£350	Medicine	£150
*History, English Literature, and Mental Science	350	Surgery	150
*Chemistry	350	Obstetrics and Gynaecology	150
*Anatomy and Physiology	350	Materia Medica and Pharmacy	150

Lectureships.

Medical Jurisprudence and Hygiene (2) each	£40	Fever Cases	£20
---	-----	--------------------	-----

* Full-time appointments.

The teaching of Irish has been most abundantly provided for, so as in some sense to meet the clamour which has been raised in favour of an "Irish" national university. Thus in the Dublin University College there will be a professorship of Celtic Archaeology and Antient Irish History, £600; a professorship of Early Irish, £600; Modern Irish Language and Literature, £600; a lecture on Modern Irish History, £250; and a lecturer on Irish Language, £150 a year. In Cork University College there will be a professor of Irish Language and Literature at £450; a lectureship on Modern Irish, £150; a lectureship on Modern Irish History, £250; a lectureship in Irish Language, £250. In Galway the professor of Modern Irish will receive £300, on Celtic Philology, £150.

In the case of Galway there is a curious innovation. In a medical school, which in the senior subjects exists with some difficulty, there are to be two lectureships on Jurisprudence and

Hygiene at £40 each, and a lectureship on Fever Cases at £20. Some one is to benefit by this arrangement, but the western school will hardly have its glory increased by providing for a specialist in fevers.

THE ROYAL UNIVERSITY OF IRELAND.

The Calendar of the Royal University of Ireland for the year 1909 has now been published in two volumes, containing together some 1,300 pages.* The first volume, in addition to other information, shows that 4,135 students entered for examinations in the various faculties during the year 1908, and that 2,575 of them were approved. Of the remainder 1,377 were rejected, the balance either failing to appear at the examinations or retiring during their progress. The second volume furnishes copies of the papers set.

UNIVERSITY OF EDINBURGH.

UNIVERSITY COURT.

A MEETING of the Court was held on May 17th.

Recognition of Teachers.

Sir John Battie Tuke and Dr. John Keay conjointly were recognized as teachers in mental diseases.

Examiners.

On the recommendation of the Senatus, Dr. Martin, Director of the Lister Institute of Preventive Medicine, London, and Professor Ewing, Royal Naval College, Greenwich, were appointed additional examiners of theses submitted for the degrees of D.Sc.

Carnegie Trust.

Principal Sir William Turner was reappointed the university's representative on the Carnegie Trust for the universities of Scotland.

Usher Institute.

Mr. Sydney T. Champaloup, M.B., Ch.B., was appointed an assistant in the Usher Institute in connexion with the bacteriological work of the city.

UNIVERSITY OF BIRMINGHAM.

The Visit of the King and Queen.

The announcement of the intended visit of the King and Queen has already had a stimulating effect in relation to the university's appeal for more funds. During the last few days a number of donations, amounting together to nearly £1,000, have been promised. Others are expected to follow, and the council of the university will shortly publish the first list of contributions.

Honorary Degrees.

It is intended to confer honorary degrees on certain distinguished men of science, letters, medicine, and commerce at a special congregation in July. The congregation will probably follow immediately on the King's visit. These will be the first honorary degrees conferred by the university.

The Huxley Lecture.

Sir E. Ray Lankester, F.R.S., has resigned his appointment as Huxley Lecturer for the coming session, and Professor W. Bateson, F.R.S., of the University of Cambridge, has accepted an invitation to fill the vacancy. The Huxley Lecture will probably be delivered in October or November.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

COUNCIL ELECTION.

The Secretary has circulated the usual annual announcement that a meeting of the Fellows will be held at the college for the election of Fellows into the council. The date on this occasion will be Thursday, July 1st, at 3 p.m., and the vacancies are three in number, being occasioned by the retirement in rotation of Mr. A. W. Mayo Robson, Sir W. Watson Cheyne, Bart., C.B., and Mr. R. Clement Lucas. Blank forms of the requisite notice from a candidate and of his nomination may be obtained on application to the Secretary, and must be received by the Secretary, duly filled up, not later than Friday, June 4th. The voting papers will be distributed to each Fellow, whose address in the United Kingdom is registered at the college, on Tuesday, June 15th. Our usual analytical list of the members of council, giving their date of election or re-election will be found in the JOURNAL of May 22nd, pp. 1271-2, and we have added, as usual, a note of the proportional representation of the metropolitan medical schools and the provinces.

We are informed that Mr. Clement Lucas, and probably Sir W. Watson Cheyne, will offer themselves for re-election, and we understand that Mr. W. Harrison Cripps and Mr. W. H. Jessop, both of St. Bartholomew's Hospital, will be candidates, the latter as an ophthalmic surgeon.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

FELLOWSHIP EXAMINATION.

The following candidates have been approved at the examinations indicated:

FIRST FELLOWSHIP.—R. H. Barter, F. C. Crossle, J. L. Lunham, Captain I.M.S.; P. M'Cartan, S. A. M'Sweeney.
 FINAL FELLOWSHIP.—A. Chalmers, Captain I.M.S.; J. H. Dauber, S. Endlish, T. H. Hay.

THE ROYAL COLLEGE OF SURGEONS OF
EDINBURGH.

New Fellows.

THE following gentlemen were elected Fellows at a meeting of the College held on May 19th: J. M. Christie, J. Gilmour, R. T. Jupp, A. D. Macintyre, J. S. Mitchell, G. Raffan, H. Spiers, C. E. Tewsley, R. W. Townley.

Medal Competitions.

The Bronze Medal and Microscope presented to the College by Colonel William Lorimer Bathgate, in memory of his late father William McPhune Bathgate, F.R.C.S.E., Lecturer on Materia Medica in the Extra-Academical School, was awarded to Miss Marion Macintyre.

The first annual award of the Ivison Macadam Memorial Prize in Chemistry, consisting of a bronze medal and case of instruments, was made to Mr. C. H. Kembell after a competitive written examination in chemistry.

APOTHECARIES' HALL, DUBLIN.

THE following candidates have been approved at the examinations indicated:

FIRST PROFESSIONAL.—G. M. Mayberry, B. J. M. Neary, M. O'Donnell.

THIRD PROFESSIONAL.—E. Murphy, J. J. O'Mullane, G. Andeen.

FINAL.—G. H. Fisher, J. J. O'Mullane, J. H. Nichol, S. E. David.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved at the examinations indicated:

SURGERY.—H. H. Clarke.

MEDICINE.—†J. J. Cyriax, †A. H. C. Dawes, †J. A. Laughton.

†W. E. North-Smith.

FORENSIC MEDICINE.—J. A. Koch, J. W. Williams.

†Section I.

†Section II.

Obituary.

WILLIAM WOTHERSPOON IRELAND, M.D. EDIN.

On May 17th Dr. W. W. Ireland peacefully passed away at his home, Victoria Terrace, Musselburgh, in his 77th year. The son of an Edinburgh publisher of some note in his day, and was a lineal descendant of Mrs. Welsh, daughter of John Knox, the Reformer. He studied medicine at Edinburgh University and in Paris, graduating as M.D. Edin. in 1855. He obtained an assistant surgery in the H.E.L.C.S., and was attached to the Bengal Horse Artillery throughout the Mutiny. During the siege of Delhi (of which he afterwards wrote an account) he saw Lieutenant (now Lord) Roberts wounded, and attended him; finally, after seven months' campaigning, Ireland himself received the wound of a bullet which destroyed one of his eyes, and passing round the base of the skull towards the opposite ear was extracted from that situation. This wound led to his retirement from the service, and after some time spent in a prolonged convalescence at Madeira and a sojourn on the Continent (during which he wrote a novel, *Randolph Methyl: A Tale of Indian Life*), he returned to his native country to take up the post of Medical Superintendent of the Scottish National Institution for Imbecile Children at Larbert, succeeding his friend Dr. Brodie, whose obituary he published in the *Journal of Mental Science* as recently as April last. For several years Dr. Ireland filled this post with much distinction, taking the utmost scientific interest in his work; and in 1877 he published the result of his observations in a large volume entitled *On Idiocy and Imbecility* in the first edition, and later (in an extended form) *The Mental Affections of Children*. This book obtained the position of a classic on the subject of which it treats, and laid the foundations of a classification of the varieties of idiocy and imbecility which has been widely chosen. Dr. Ireland's literary efforts were not, however, restricted to the speciality which he had chosen; his linguistic attainments affording him ready access to whatever of neurological and psychiatric interest appeared in the publications not only of this country and America, but of the Continent, and he was a voluminous contributor to medical journals (and especially to the *Journal of Mental Science*) of reviews and digests of all that was notable in this department of medicine. He wrote several important articles in Hack Tuke's *Dictionary of Psychological Medicine* and in the *Edinburgh Medical Journal*. Dr. Ireland had always a bent for historical research and delighted in studying historical characters from the standpoint of the

psychologist, as may be seen in his interesting works, entitled *The Blot upon the Brain* and *Through the Ivory Gate*; and of late years he had been engaged in dealing with the period of the Commonwealth and of the Civil War, and published in 1905 *The Life of Sir Henry Vane*.

On the fiftieth anniversary of his graduation Dr. Ireland was the recipient of a jubilee gift and illuminated address, subscribed for by numerous friends. Dr. Clonston, in making the presentation, referred to the varied and valued nature of Dr. Ireland's work, and congratulated him on his having made his mark, not only in medicine but "in literature, in science, and in history, and on his having opened up a new path in biography by the application of medico-psychology and studies in heredity in the elucidation of the lives of men who have made history."

Dr. Ireland's personal character endeared him to all who knew him. Of distinguished personal bearing and of keen mental activity, his manner was unassuming, and with earnestness and love of justice and truth he combined a geniality of manner and pleasing humour which rendered him a welcome guest at the medical gatherings, both at home and abroad, to which he was a frequent visitor.

After his resignation of his post at Larbert, Dr. Ireland for some years had a private establishment for feeble-minded children at Prestonpans and at Polton, but retired, after his wife's death, to Musselburgh. He leaves behind him a son, Dr. Thos. Ireland, late of the West India Medical Service, and a daughter to mourn his loss.

ERNEST ALFRED SNAPE, M.D. BRUX., L.R.C.P. LOND.

WE regret to have to record the death of Ernest Alfred Snape, who died at his residence, 41, Welbeck Street, on May 11th. He was the eldest son of the Rev. W. A. Snape, M.A., for many years Vicar of Bury St. Edmunds, and was born in London in 1864, educated at the Merchant Taylors, Bury St. Edmunds Grammar School. Afterwards he became a medical student at Charing Cross Hospital, where was Gold Medallist and Pereira Prize-man. He became L.S.A. in 1887, L.R.C.P. Lond. in 1889, and M.D. Brux. in 1893.

He held the posts of House-Physician and of Electrical Assistant at Charing Cross Hospital, and afterwards was for some time Resident Medical Officer at the Welbeck Street Dispensary. When he gave up this appointment, he started in general practice in Welbeck Street, where he lived till the time of his death.

He was Honorary Physician to the Cripples' Home, Marylebone, and of the Governesses' Benevolent Institution, and was at one time President of the Brussels Medical Graduates' Association, a Fellow of the Royal Society of Medicine, and of the British Balaenological and Climatological Society. He was recently elected a Representative of his Division on the Metropolitan Branch Council of the British Medical Association.

He was joint author with Dr. W. K. Sibley of a report on all the special hospitals in London with reference to the question of hospital abuse, which was prepared on behalf of the Hospital Reform Association, of whose Council he was a prominent member. This report was published in the *BRITISH MEDICAL JOURNAL* in April, 1897, and also in the *Lancet* about the same time.

Dr. Snape was an active Volunteer, and served as Captain in the R.A.M.C. London Companies, and at the time of his death was Captain in the 3rd London Field Ambulance R.A.M.C. 1st London Division of the Territorial Force. For many years he was an enthusiastic politician, and served as a member of the St. Marylebone Borough Council, but his increasing practice compelled him to retire some time ago.

Dr. Snape will be deeply regretted by a large circle of friends and patients. He was a good and kind friend and a staunch and loyal colleague, and always most ready to help those in need of his professional assistance. He had naturally a very cheerful disposition and genial manner, and was gifted with a considerable amount of optimism.

For some years he had had slight attacks of rather indefinite abdominal symptoms, but never severe enough to lay him up, but on Monday, May 3rd, typical symptoms of appendicitis appeared, and although successfully operated upon by Sir Watson Cheyne he succumbed to an attack of pneumonia a week afterwards. His widow was the daughter of Mr. F. Hahn, C.E., of Mexico.

The funeral took place on May 14th at St. Mary-lebone Parish Church. The first part of the service was conducted by the Rev. F. Benson-Welsh, brother-in-law, assisted by the Rev. Horace Snape, brother. Nearly 100 wreaths and crosses were sent, and the church was crowded with friends and patients, including the officers and non-commissioned officers of the 3rd London Field Ambulance, Captain Langford-Lloyd and permanent staff of the R.A.M.C., representatives from the Governesses' Institution, etc. The body was afterwards cremated at Golders Green. The ashes were deposited in the Highgate Cemetery Columbarium.

CHARLOTTE LOUISA ELLABY, M.D., L.S.A.,

CONSULTING OPHTHALMIC SURGEON TO THE NEW HOSPITAL FOR WOMEN, LONDON.

It is with great regret that we record the death of Miss Ellaby, M.D. Paris, L.S.A. Lond., which took place on May 14th at her house in Harley Street, at the age of 55.

Charlotte Louisa Ellaby was the youngest daughter of the late Rev. J. W. Ellaby, of Woodstone, Peterborough, and it was only by the exercise of the most indomitable pluck and perseverance that she was able to enter her chosen profession. She graduated in medicine in Paris in 1884, embodying in her thesis the fruits of research work in ophthalmology undertaken while she was a student. In the autumn of that year, on the recommendation of Mrs. Garrett Anderson, M.D., she went out to Bombay to join Dr. Edith Pechey, first at a temporary hospital and afterwards as second physician to the Cama, a Government hospital for women and children. Here Miss Ellaby worked most successfully, not only in the special eye department which she inaugurated, but also in a very large out-patient department and in an increasing private practice.

After some years' work in India, desiring to devote herself entirely to ophthalmology, she resigned her appointments and returned to England. She then passed the examination of the Society of Apothecaries (which had recently been reopened to women), in order to have a registrable British qualification.

In 1890 Miss Ellaby was invited by the committee of the New Hospital for Women to organize an eye department in connexion with the hospital, and was appointed its first ophthalmic surgeon. Here she worked happily and with the success which waits upon enthusiasm controlled by the true scientific spirit, until failing health, fought with a courage little short of heroism, compelled her resignation three years ago. In the winter of 1894-5 Miss Ellaby returned to India for a few weeks, her services having been specially requisitioned to perform a double cataract operation upon the Rani of Jamnagar. The operations were successful, but it was partly to this visit to India that Miss Ellaby attributed her subsequent ill-health. At the time of her death she was Consulting Ophthalmic Surgeon to the New Hospital for Women, Lecturer on Ophthalmic Surgery to the London School of Medicine for Women, and a member of the Faculty of Medicine of the University of London.

Her literary contributions to scientific journals included essays on the amplitude of convergence and on the action of strychnine and the constant current on the normal eye, and a report on a series of cases of retinitis observed in the wards of the New Hospital and elsewhere.

WILHELM ENGELMANN,

PROFESSOR OF PHYSIOLOGY, BERLIN.

Our Berlin Correspondent writes: Professor Th. W. Engelmann, du Bois-Reymond's successor in the chair of Physiology at the Berlin University, died on the 20th instant in his 66th year.

Engelmann was a Saxon by birth, and studied in Germany, but it was in Holland that his chief lifework was done. For more than thirty years he formed one of the chief ornaments of the Utrecht University. On du Bois-Reymond's death in 1897 Engelmann accepted a call to fill the vacant place, and thus became Professor of Physiology and Director of the Physiological Institute in Berlin, a post which he held until last Easter recess, when ill-health obliged him to resign it.

We owe to Engelmann a large number of valuable contributions to physiological science, the most important being, perhaps, his researches on the subtler relations subsisting between nerve and muscle, on the electric phenomena of nerve and muscle, and on the development of pseudo-electric organs. He was one of the first to investigate the difficult problem of psycho-physiological processes in the lower forms of life, and in his researches on the relation between light and plant life he laid the foundations of the theory of chemotaxis.

In private life Engelmann was communicative, thoroughly cultured, and of a gentle humour. Music was his passion, and even in the stress of work he never neglected his violoncello, which he played with taste and skill.

The death is announced, at the age of 62, of Dr. HOPGOOD, of Sunderland. He had an attack of illness last July, but appeared to have recovered; on May 22nd he was found dead in bed, having evidently expired peacefully in his sleep. Thomas Frederick Hopgood was born at Chipping Norton, where his father practised medicine. He studied at University College, London, where he won the Fellowes clinical medal, and was medallist also in surgery, in medical jurisprudence and pathology. He took the diplomas of M.R.C.S., L.R.C.P. Lond., and L.S.A. in 1867, and after acting as House-Surgeon at the Royal Surrey County Hospital was appointed to a similar office at the Sunderland Infirmary. In 1874 he became Honorary Surgeon to the Sunderland and Durham County Eye Infirmary, then carried on in a small house, and continued to work for it for thirty-five years; he became greatly interested in its development, and was undoubtedly the means of getting the present institution built. For thirty years he was Surgeon to the Sunderland and Bishopswearmouth Infirmary, and on his retirement about a month ago he was presented with his portrait by the committee. Dr. Hopgood was widely known and respected throughout the town and district, and regret at his death is general among all classes of the community. He had been a widower for many years, and leaves three daughters and three sons, two of whom are now studying for the medical profession.

Public Health

AND

POOR LAW MEDICAL SERVICES.

BOARDS OF GUARDIANS AND EXTRA MEDICAL FEES.

PARISH DOCTOR (a district medical officer) writes saying that he has recently attended Mrs. S—, a pauper in receipt of medical relief, who required attention for five weeks after confinement on account of whiteleg. Our correspondent made a claim for £2; the guardians replied in writing that though they acknowledged his special kind attention to this patient, they objected on principle to pay more than the ordinary fee. He asks, Have I any remedy?

* By Article 183 of the Consolidated Order of the Local Government Board, bearing date July, 1847, our correspondent is clearly entitled to be paid a fee of £2 for his attendance on this case of phlegmasia dolens, which must be regarded as a puerperal affection unmistakably due to the antecedent confinement. We therefore recommend him to insist on this amount being paid. The other case on which he refers to us for advice we recommend him not to press further. Article 181 is permissive.

POOR LAW OFFICERS AND SUPERANNUATION. DISTRICT MEDICAL OFFICER writes as follows: I have just resigned after eight and a half years' service a position as district medical officer to one of the unions, and as my retirement is not due to "ill health or bad conduct," the board of guardians will not allow my claim for return of contributions to the superannuation allowance. The matter seems very unjust to me.

* We are sorry to find our correspondent in the position he describes—unable to claim any return of his contributions already paid towards superannuation, but Clause 8 of the Superannuation Act is quite clear on the point, and prevents any return of contributions after voluntary resignation of office even if the guardians wished to do so.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.
The offices of the British Medical Association and of the British Medical Journal are at 429, Strand, London.

Communications respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the British Medical Journal is *Articulate, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National).—

2531, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2530, Gerrard, BRITISH MEDICAL ASSOCIATION.

2534, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

CONFIDENTIAL SECRETARIES AND TYPISTS.

TYPIST asks how those medical men who employ typists and other lay helpers in their notes and correspondence arrange for professional secrecy? I am minded to get such a helper myself, but I hesitate because I do not see how I can keep matters which at present I regard as private, private then. I may say that, doing only special work, I write somewhat full notes.

MEMORY TRAINING.

R. E. D.—We have no special knowledge of the system of memory training in question, but have reason to believe that system may do much to develop the faculty of memory in persons in whom it is defective. Besides increasing the facility with which various things are remembered, a properly arranged system may develop what is even more often lacking than mere capacity to remember, namely, the power of storing facts in some orderly fashion ready to bring out as occasion arises. It is impossible, however, to assess the probable value of such training in the case of any individual learner, or to say whether it is worth while to pay any given sum for printed instructions how to follow a system. It would not be difficult for any thoughtful person to devise for himself a system suitable to his own particular needs.

ANSWERS.

PRURITUS PUERILI.

W. W. writes: "Baffled" (BRITISH MEDICAL JOURNAL, May 15th, p. 1216) does not mention the use of any constitutional treatment. It would be worth his while to reduce the patient's diet to 20 or even 12 oz. of solid food per diem, in two meals. The latter was the figure under which Luigi Cornaro prolonged his life to 100 years. I have known it successful in pruritus ani. Liquids not alcoholic may be taken freely, but milk must be calculated as one-third solid.

LETTERS, NOTES, ETC.

AUSTRALIA FOR THE SONS OF MEDICAL MEN.

DR. RICHARD ARTHUR (President, Immigration League of Australasia) writes: Some time ago you were so good as to allow me to call attention to the opportunities which life on the land in Australia offered to lads and young men, and to point out what excellent avenues to this the various Government agricultural colleges were. At these institutions an admirable training in scientific and practical agriculture in all its branches can be obtained at a cost of from £20 to £30 a year, including first-class board and lodging. After finishing the course fertile land in a district of good rainfall can be obtained on reasonable terms for either sheep, wheat, dairying, fruit growing, or mixed farming. As a result of this many doctors wrote to me, and some have already sent out their sons. I am at present in London, and will be glad to correspond with any others or arrange an interview with them. My address for the next two months will be the Royal Colonial Institute, Northumberland Avenue, W.C.

I have visited most of these colleges myself and so can speak from experience. I hope to make arrangements for a lantern lecture on the Australian agricultural colleges, to be given at Belfast when the British Medical Association is meeting there, and to be present myself to see any medical men who may desire further information.

AN APPEAL.

IN the JOURNAL of May 15th an appeal was published on behalf of a medical practitioner in Dublin who through no fault of his own is in distressed circumstances. It is signed by the Presidents of the two Royal Colleges in Dublin, by Sir John W. Moore and Sir Charles R. Cameron. The following subscriptions have been received:

	£	s.	d.
Sir Charles A. Cameron, C.B., Dublin	...	5	0
Dr. Ninian Falkiner, Dublin	...	1	0
Dr. Charles Gibbs, London	...	2	0
"Anonymous" (University of Leeds)	...	2	0
John Brown, Esq., M.D., D.P.H., Buncup	...	0	6
E. C. Cornack, Esq., M.D., Villa d'Alsace, Vichy	...	1	0
Postal Order, Devonshire Street, London, W.	...	1	0
Well-wisher, Boscombe, Bournemouth, Hants	...	1	0
"Anon." Exeter	...	1	0
Sir John Moore, M.D., Dublin	...	2	0
Dr. I. Burney Yeo, London	...	2	0
Dr. Maguire	...	0	6
Sir Stewart Woodhouse, Dublin	...	3	0

"AURAL AND OTHER VERTIGO."

IN a further note on the advantage of wearing loose neck clothing, Dr. W. G. Walford of Finchley Road, N., records several instances in connexion with sea sickness. They concern persons who, previously indifferent or bad sailors, found themselves quite comfortable in really bad weather after having adopted for some months the practice of wearing loose neck clothing. Dr. Walford gives some further particulars of the attack of cerebral congestion in his own person which after four months he found to be due to neck clothing not tight, according to conventional ideas about collars and the like, but tight enough to interfere with free venous flow from the head (see BRITISH MEDICAL JOURNAL, May 1st, p. 100). In addition to giddiness and other symptoms he had diplopia for eight days, and could not walk steadily, especially in the dusk. A thrombus in a small cerebellar artery was diagnosed. His illness, he says, resembled what is known by veterinary surgeons as "staggers." In horses this is due to tight throat lashes, and in dogs to tight collars.

MEAT POISONING AND COOKEEY.

DR. A. W. GILCHRIST (NICE) writes: Dr. McWeeney's recent observations on an outbreak of meat poisoning at Limerick (BRITISH MEDICAL JOURNAL, May 15th, 1909, p. 1171) are of a nature that should excite widespread attention. Why is such a pathetic disaster possible? Is it not a bitter reproach to our boasted scientific age that nine valuable young lives should fall a sacrifice to one of the least unavoidable of causes? Dr. McWeeney remarks, in concluding his exceptionally able report, that the practical lesson to be learnt from this is twofold. First, it indicates the need for the abolition of the private slaughterhouse... secondly, it emphasizes the danger arising from the use of old, stale scraps of meat. "Especially of beef," adds the writer. May I suggest another reflection of a general order? Should it not invoke the necessity for more thorough food reform? It is difficult to conceive of such a disaster happening in France. In an industrial school managed by a French sisterhood the whole economy of the kitchen would probably be different in every essential respect. The amount of meat consumed would be smaller, but the mode of preparation would be more elaborate and careful. Much more time and interest would be devoted to the kitchen. Leguminous products of all kinds would be in extensive use; peas, beans, and lentils, with their many varieties and substitutes, would be in constant requisition, and would further be wholesomely and palatably prepared. The habitual use of "purées," "pâtes," and "potages," entailing as they do lengthy heating in their preparation, would remove the danger arising from the habitual consumption of hastily prepared meats. A large poultry yard would be the natural and provident annex of the pantry and kitchen, and eggs therefore in constant use. Nor would the domestic economy I refer to be disturbed by complicating systems of dietetics. A good *cuisine bourgeoise* is unexclusive, and aims only at providing an ample, safe, and appetising table.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	...	0	4
Each additional line	...	0	6
A whole column	...	2	15
A page	...	8	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at Postes Restantes addressed either in initials or numbers.

A Clinical Lecture

ON THE

NEUROTIC ELEMENT IN DISEASE.

DELIVERED AT THE LONDON SCHOOL OF CLINICAL
MEDICINE.

BY

GUTHRIE RANKIN, M.D., F.R.C.P. LOND. AND ED.,

PHYSICIAN TO THE BREADSTREET AND ROYAL WATERLOO
HOSPITALS, LONDON.

SINCE the time when Adam and Eve were banished from the Garden of Eden mankind has been familiar with disease; but as the race has progressed from one stage of development to another, civilized humanity has gradually been learning how to mould its habits of life so as to rob sickness of many of its terrors, and subdue it to the influence of laws by which it is ever becoming more completely and effectively controlled.

In furtherance of this aspiration for betterment, scientific hygiene is constantly recording fresh triumphs. Some diseases, such as typhus fever, small-pox, scurvy, and Malta fever, are thoroughly under the control of preventive measures; while others, such as diphtheria, enteric fever, tuberculosis, and scarlet fever, though not yet so completely governed, are capable of being limited in the extent of their distribution and modified in the severity of their manifestations. These disorders belong, it is true, to the specific or communicable class of disease which preventive medicine most readily combats, but in other varieties of sickness no less remarkable progress has been made in the direction of amelioration.

Syphilis, in spite of all its dreadful possibilities, is amenable, if properly managed, to the influence of mercury, the iodides, and apparently also to the more recently discovered arylarsenates; myxoedema can be cured by thyroid gland extract; malaria sacrifices its protozoal parasites at the shrine of quinine; chlorosis vanishes under the revivifying influence of iron and arsenic; and the present investigations into the nature of cancer may be trusted to devise, in the near future, methods of prevention and treatment by which that widespread scourge will be held in check.

In the field of surgery the advances of scientific discovery and the improvement of technique have been no less remarkable than in medicine, with the result that many disorders which were formerly regarded as hopelessly incurable are now brought within the scope of successful treatment.

But while great gains have been achieved in the conflict against organic and specific disease, the record is by no means so satisfactory when we come to investigate the vast field of functional disorders with which we are brought in constant contact. It may be safely asserted that our knowledge of functional disease is still of the most limited description, and yet it must be confessed that functional symptoms are rapidly acquiring increased pre-eminence in every variety of illness. Those who come after us will certainly find, with more accurate and penetrating methods of research, minute organic changes to adequately explain many manifestations which, in our ignorance to-day, we label functional.

This neurotic tendency is becoming so general, that not only are the ordinary organic and specific disorders influenced by its complicating coexistence, but it has also come to establish for itself a symptom-complex known under the name of "neurasthenia," which though possessed of such distinctive characteristics that it can be scheduled as a disease-entity, is yet, so far, unaccompanied by any organic changes by which a *post-mortem* explanation is yielded. All we are able to say is that the seat of disorder is situated somewhere in the nervous system, and that the manifestations of a condition with which we are becoming more and more familiar, are obviously dependent upon disturbance of the great nerve supply by which the activity of the bodily functions is controlled and the stability of the mind itself provided for.

It has been asserted that the main cause of this great change which is taking place in nerve resistance to the powers of evil is the more rapid pace at which the world

moves, and the consequent increased strain which daily life and duty imposes upon each individual's reserve of energy. That, in addition to these necessary calls upon our vitality, we are becoming too luxurious, and are striving to enter the kingdom of Heaven by the preaching and practice of a gospel of comfort rather than by the older doctrine of self denial and hard work.

Whatever the true explanation be, it is certain that we, as physicians, are coming to recognize that the old order of things in disease is rapidly changing, and that in our management of the sick, new conditions are creeping in which are tending to modify the course of many organic ailments, and are compelling us to direct our methods of treatment so as to counteract their hindering influence upon the natural progress of this, that, or the other disorder.

Many diseases, indeed, are so different now from what they used to be that we believe them to be undergoing a change in type. This is not surprising when we consider how mankind is gradually being altered by the influence of circumstances and surroundings, and we begin to appreciate that the greatest change both in man and his ailments is dependent upon a progressive development of nervous instability. It may be objected that the perception of an increasing nervous element in disease depends in great measure on the preconception or bias of the observer, and to some extent this may be true.

But the observation of this growing neurotic influence is no longer that of a few physicians only; it has become the admitted experience of most men who are engaged in active work; so that such criticism may be regarded as applicable in only a comparatively small number of instances.

It is not my intention to direct your attention this afternoon to those neurasthenic conditions which may be said to be entirely central. The manifestations by which ordinary neurasthenia declares itself are familiar to most of us, but I may be allowed to recount the following epitome of its multifarious symptoms, in order to emphasize the fact that the only satisfactory explanation of such a complex picture is to regard it as the outcome of a central or constitutional upset: A constant sense of weariness and inability for sustained mental or physical exertion; impairment of digestion; disturbed sleep; restlessness and irritability; occipital or vertical headaches; vasomotor instability; feebleness of volition, loss of memory, and mental depression; and absence of physical signs, indicative of organic disease. What I desire more especially to consider with you to-day is the effect of a generalized neurasthenia or of the neurotic habit upon the progress of ordinary illnesses. And, in the first place, may I say that in my experience the distinctively neurasthenic type of person does not come out of surgical operations well. An operation is got through as in average cases, but no sooner is all anxiety as to recovery over than the neurotic element asserts itself more strongly than before, and ultimate convalescence is delayed—sometimes indefinitely. Here is a case illustrative of my meaning, and it is one of many I could mention:

A married lady, aged about 48, who belonged to a family of a highly neurotic type and who had herself suffered for several years from anaemia and neurasthenia, developed indefinite discomfort in the region of her appendix. This discomfort increased until it became actual pain, but was never accompanied by pyrexia or any evidence of active inflammatory mischief. In the right iliac fossa a sausage-shaped mass could be felt, which varied in size from lime to lime, and was situated in the midst of a resistant elastic mass. She very much dreaded operation, but she was advised that without removal of the appendix she need not expect any relief to her sufferings. In due course the appendix, which was found glued to the caecum, was removed, but recovery was so slow that the patient was unfit to return home for two months. Her nervous system became completely unyielding; she slept badly, could neither take nor digest food except in the smallest quantities, was constantly depressed, became exceedingly thin, suffered from general depression, and was altogether distinctly worse in her general condition of health, and especially in the state of her nervous system, than she had been before the operation. After her return home she did not recover, but for the following seven months was a confirmed invalid; even the pain for which her operation had been principally undertaken returned as badly as before.

I do not suggest that an operation was unjustified; I merely relate the case as one of a type in which surgical

interference is not well tolerated, and in which due consideration ought to be given to the general health as well as to the local condition before surgical methods of treatment are employed. If an operation is imperatively demanded to save life, all the consequences which may ensue must be risked; but there are many instances where the urgency is not great, and in some of them sufficient allowance is not made for the neurotic element which sometimes renders the diagnosis a little uncertain, and always impresses upon the physician the likelihood that complete recovery will be slow. The wound may heal as well and as speedily as in the case of other patients, but the nervous system does not rebound well from the shock of operation, and for a longer or shorter time—and much longer than most surgeons will admit—remains difficult of control and rebellious to restorative treatment.

It would be obviously impossible in the course of one short lecture to enumerate every disease the usual photograph of which may be blurred by the interpolation of neurotic lights and shadows. I desire only to refer to the subject in broad outline, in the hope that I may succeed in stimulating your interest sufficiently to make you investigate your cases with minds alert to the frequency with which the nerve element may not only modify the picture but even transmute it almost beyond recognition.

Let us, in the first place, glance for a moment at the diseases of the brain and nervous system generally. I need scarcely remind you that the various paræsthesiæ of functional disturbance are liable to cause in the neurasthenic mind the most grave dread of organic disease. Especially do neurasthenic patients readily fall into the fear of an imminent paralysis or apoplexy.

As an instance, I may quote a lady of 64 years of age who has come to see me from time to time over many years, and always with the same tale of numbness in her fingers and toes, a sense of formication down her right side, occasional headache and vertigo, and a record of failing memory and intellectual confusion. She is of a gouty habit of body, has considerable tension in her circulation, thickened vessels, and ineffective action of the bowels with a consequent liability to recurrent conditions of fecal accumulation in her colon. Up to the present she has always been restored to comfort and confidence by remedies directed to the proper evacuation of her bowels and the reduction of her arterial tension.

The neurotic predisposition of the patient is awakened into activity by an autointoxication from her intestine, and so soon as the primæ viæ are thoroughly cleared her normal equanimity is restored. But the manifestations, which so far have been functional only, point the way clearly to hidden rocks of organic danger ahead, and lend value to symptoms which, though not at present synonymous with the paralysis which she dreads, foreshadow to the professional mind a possible future verification of her fears.

Another patient—this time a full-blooded, freely-living man of 50 years of age, whose family has been gouty through many generations and several of whose ancestors have succumbed to apoplexy—comes to me periodically in terrible anxiety that he is on the verge of falling a victim to what he calls "the family scourge." He is a highly strung man and knows just enough about the signs of apoplexy to have his fears aroused by every headache that befalls him. So far, his headaches have all been of the occipital neurasthenic type and have been accompanied by such unmistakable confirmatory evidence of a passing nervous tension that one has been able to reassure him and to set his health re-established by suitable dietetic and medicinal correctives. But, again, the presence of high arterial pressure, a low specific gravity of the urine, occasional vertigo, and a sluggish portal circulation cast the shadow of organic illness across these chapters of functional disturbance in his life-history, and the problem recurs with increasing insistence whether the functional storms of his present period of life are not the heralds of a coming organic tempest that will some day add another victim to the roll of his family record.

The occurrence of "fits" is an incident in the history of many illnesses which gives rise often to difficulties in diagnosis and in differentiation between a functional and an organic foundation. Two cases of a widely different type, which were sent to me on account of what were described as "fainting attacks," are instructive in this connexion.

One of them, a young lady of 23 years of age, was of neurotic type, and was a descendant of a family through many generations of which there could be traced a strain of nervous instability. The girl, though shy and retiring in manner, was healthy-looking and without any definite organic fault.

Her health had been quite good until about a year before her first visit to me, when she began to complain of lassitude, disturbed sleep at night, failing appetite, vertical hiccoughs, vertigo, constipation, and fainting attacks. These attacks were said to be accompanied by temporary loss of consciousness, by pallor, palpitation, and dyspnoea, and were always followed by headache, but she had never bitten her tongue, never been convulsed, never passed water involuntarily, and never hurt herself in falling. The story did not suggest epilepsy, and her heart was normal. At first sight it seemed as though the "fainting fits" were either purely neurotic or merely a consequence of some passing gastric disturbance. But on question and investigation she proved to have a slight degree of intention tremor, a certain amount of nystagmus on extreme deviation of the eyeballs in the lateral direction, exaggerated knee-jerks, and a suspicious pallor of the temporal half of her right optic disc—all symptoms very slight in themselves, but when taken in conjunction with the girl's age, with her heredity, with an apparently idiopathic development, and with a certain degree of mental hebetude to which she had been previously a stranger, enough to raise in one's mind the question whether we were faced with something more than a mere functional disturbance of health—whether, in fact, we were not dealing with a disseminated sclerosis in the earliest stages of its development. The present condition of this patient, after a few weeks' treatment, is one of marked improvement, but the fact must not be lost sight of that no disease of the nervous system is so strikingly marked by remission of symptoms as disseminated sclerosis. In such a case, therefore, judgement should be suspended and no definite diagnosis ventured upon until a sufficient lapse of time enables us to conclude definitely that the threatening indications have been part only of an entirely functional condition, and have not been the early expression of tissue changes which will, later on, declare themselves the indisputable evidences of incurable organic disease.

The other patient was a man of 51 years of age, a soldier who had served his country in many parts of the world, and had never been seriously ill until about a year ago, when he suddenly fell down in what was believed to be a "fainting fit." Since the first attack he had experienced many similar seizures, and recently they had become so frequent as to cause him and his family serious alarm. He had also developed a tendency to headaches and to vertiginous attacks, and he was concerned to observe that his memory was rapidly failing him. He had been active all his life, had indulged freely in tobacco and alcohol, but denied ever having suffered from syphilis. Though distinctly neurasthenic, he had no evidence of established organic disease, but his vessels were atheromatous, the heart was somewhat hypertrophied, and there was a ringing second sound at his aortic cartilage. His urine was of low density, and contained the faintest haze of albumen. His attacks were, from the description, doubtfully convulsive, but he was said to lose consciousness, to become during them very flushed in the face, and always on recovery was intellectually confused, abnormally somnolent, and painfully emotional. He had never injured himself during his attacks, his discs were normal, and there was no evidence of muscular paresis or paralysis. On closer examination of his nervous system his pupils, though active, were sluggish; there was a suspicion of shivering in his articulation of certain words, and his tongue betrayed a slight fibrillary tremor. What was the nature of these attacks? The description of them, and the fact that they first declared themselves after middle life, made it unlikely that they were wholly functional, though his obvious neurotic tendencies suggested that explanation, and doubtless accounted for many of his symptoms. Further, the onset of idiopathic epilepsy is unusual so late in life, and if the attacks were even partially epileptic, there must be some early organic change to account for them. The minor symptoms which this patient presented warranted, I think, the suspicion that on a functional basis there was being developed an organic superstructure, the true nature of which was probably general paralysis. Time will declare whether such a suspicion is well founded, but at its present state of development this case is one which again conveys the lesson of the need for suspension of judgement until sufficient opportunity is afforded for deciding whether the neurotic element constitutes the whole story or part of it only.

If we next turn our attention for a moment to the circulatory and respiratory systems as we find them involved in diseases of the thoracic organs, we will discover equally striking examples of the pitfalls which beset the diagnostic path. And, in passing, let me say how misleading to the public a medical opinion, especially in respiratory or circulatory disorders, often is. Misleading because the doctor, either to safeguard his reputation or to shield imperfect knowledge, frightens the wits out of a nervous patient by declaring that he is suffering from weak lungs or from a feeble heart. Such a verdict means to the patient and his relatives a conviction of consumption in the one case, and the likelihood of sudden death in the other, and is generally given in cases where cough has been a persistent and troublesome symptom, or where what are described as fainting attacks have been to the patient or his friends alarmingly suspicious of heart disease.

Some years ago I saw a gentleman of 38 years of age who for a long time had been troubled with a cough which varied in degree and sometimes disappeared for weeks at a time, but always returned without any apparent reason to account for it. He had suffered much from many physicians, and had been seriously perturbed by being told in the early history of this cough that his lungs were feeble, though perhaps not actually diseased. He had taken drugs *ad nauseam*, had been sent to winter abroad, and had also undertaken a voyage to New Zealand to rid himself of his enemy. When I first saw him I was unable to find any evidence of active disease in either lung, though I thought there was some suspicion of rough breathing in the right upper lobe. The physical signs, however, were merely of a slight and indefinite to account for a cough of such long duration, and the patient, despite his long experience of "weak lungs," was well nourished and able for quite an average amount of professional work and physical exertion. He was a highly nervous man, by profession a solicitor, and was living in constant dread of tuberculosis. He indulged extensively in cigarettes, and his fumes showed clear evidence of the irritating effects of tobacco-smoke inhalation. To relieve the annoyance of his cough he was in the habit of taking glycerine, and it had become his habit to keep in his dressing room a bottle of this harmless substance for use when required. One night, shortly after retiring to rest, the cough became, as it often did, worrying, and he resorted as usual to his placebo; but, being unable to find a light, he groped his way in the dark to where he was accustomed to find his glycerine bottle, and hurriedly took a spoonful of the material, and swallowed it. He was, unfortunately, he discovered his mistake before he had swallowed much of the irritating liquid; but, in acute alarm at his mistake, he sent for the nearest doctor, who found that, though very little of the ammonia had reached his stomach, sufficient had been taken into the buccal cavity to shrink up much of the mucous membrane of his mouth, tongue, and fauces. No serious damage had been done, and, after a few days' discomfort, he recovered completely. But the satisfactory outcome of his carelessness was that thenceforth the cough, which had been for so long the enemy of his happiness and peace of mind, entirely disappeared, and he remains to-day a healthy and active member of society, with all the old dread of consumption no more than a memory of the evil influence which a careless diagnosis of "weak lungs" had exerted upon a sensitive and overstrung nervous system.

As an example of the disastrous effect of a loose diagnosis of "weak heart," may I also relate to you a case which is still under my observation?

The patient is a young, anaemic, neurotic woman of 21. She is said to have suffered from fainting fits for about two years, and her parents had been warned that these attacks were due to heart feebleness, that they were not without danger, and that she had a murmur. On close inquiry it was ascertained that, though she experienced feelings of faintness from time to time, she never entirely lost consciousness. The heart was excitable, its rhythm was slightly irregular, and a soft systolic murmur of its heard at the apex and over the pulmonary area, but the cardiac diameters were normal, and, after a little reassurance, the rapidity of the heart diminished, and the irregularity of its action entirely disappeared. It was obvious that the girl was not suffering from any organic lesion of her heart, but what her condition more strongly suggested was the possibility of *petit mal* as the explanation of her attacks. Under the influence of iron and arsenic, together with the restoration of her digestive activity, however, the faint feelings have disappeared, and the patient is now robust and well. Her own fears, as well as those of her parents, have been allayed, and the bogey of heart disease has been restored to the oblivion from which there never was any good reason for calling it forth.

Cases such as these are eloquently graphic of the evil which constantly ensues from faulty observation and enigmatic diagnosis. Actual disease of the lungs in the one case, or of the heart in the other, was not asserted, but in each instance the faulty judgement of a neurotic patient was encouraged to accept a needlessly apprehensive conclusion from the suggestive terms in which a halting and covering opinion was expressed.

But there are other thoracic disorders of greater importance than these, in which it is essential to carefully weigh the value of the neurotic element. The most distressing ailments in which we often find a jumble of organic and functional disturbance are angina pectoris in the circulatory system and asthma in the respiratory system. As you know, there are two forms of angina pectoris described—one dependent upon degenerative faults in the myocardium, increased arterial tension, atheromatous changes in the coronary and other vessels, kidney disease, and so on, which is attended by an ever-present possibility of sudden death; and another associated with vasomotor instability and neurotic accompaniments, which is regarded as unimportant and for the most part amenable to treatment by valerianates and discipline.

And there is yet another class, undescribed in textbooks, with which we are only too familiar, in which examination fails to reveal any adequate organic cause for the attacks complained of, but in which, none the less, something in the description which is given us, or something indefinite about the patient's general condition, warns our clinical instinct that there is a kernel of danger lying somewhere obscure in the recesses of the neurotic temperament which makes the prognosis uncertain. Here is such a case which I saw only a few weeks ago:

A lady of 64 years of age complained that within the past three or four months she had been frequently disturbed by unaccountable attacks of short and distressed breathing, accompanied by a sense of constriction in the chest and of tingling down both arms, but especially the left. The attacks occurred mostly at the early hours of the night, but she had also experienced several during the day after some form or other of unusual effort. She was a typically neurotic woman, and belonged to a family many members of which had suffered from nervous and mental disease. She was well nourished, bright, and active, had gouty proclivities, but presented no physical signs of organic disease other than a certain degree of thickening of her vessels and an accentuated second aortic sound. The arterial changes were not more pronounced than what is common to her time of life, and, except for the method of their onset, the description of the attacks from which she suffered was so suggestive of a neurosis that one was tempted to regard the condition as wholly functional. Not long ago this lady, after incautiously going upstairs hurriedly, was suddenly seized with acute pain in her chest which shot down her left arm and up the left side of her neck; this was accompanied by inability to move a step from where she stood, by panting respiration, and by a terrifying apprehension of immediate death. The attack fortunately did not prove fatal, but the description was too vivid to admit of any doubt as to its nature, and when I saw the lady shortly afterwards I found the heart dilated and in such a condition of irregular commotion that it seemed more than doubtful whether it could ever quiet down. She is now better, but I have learnt, not for the first time, how unsafe it is to speak too confidently about anginal attacks as being unconditionally functional.

Yet another case, more difficult to estimate and more painful in its dénouement:

A lady of 48, who was in the midst of her menopause, developed anginal attacks, which seemed, from a consideration of all the circumstances, to fully justify a diagnosis of functional disturbance and a prognosis of complete recovery later on. One day I was summoned to see her, and on my arrival at her house was told that while walking in the park she suddenly experienced a worse attack than usual, and was compelled to take a cab home. The pain gradually subsided after her return, and she lunched with the other members of her family, though not feeling quite comfortable. After luncheon she retired to her room, where I found her on the sofa, apparently better. Her pulse was rapid but regular, and she was flushed and restless. I was just about to leave her when she suddenly complained of a return of the pain; simultaneously her face became deeply cyanosed, and, before there was time to do anything for her relief, she was dead. I had examined this patient frequently, and she had also been seen by other physicians, but we were all betrayed into a wrong opinion. Leave was given to examine the heart after death, and the explanation of the tragedy—because it was nothing less—was found to be an abnormally small right coronary artery, obviously a congenital fault, which had remained mute throughout all the more active years of life, but was unable to cope with the added stress of functional disturbance coincident with the change of life.

The danger of regarding functional cases too seriously must, however, also be guarded against, and nothing can ever justify a gloomily expressed prognosis, unless under circumstances where the diagnosis is so certain that it is, for safety's sake, imperative to ring the danger bell. To frighten a neurotic patient with a verdict implying sudden fatal possibilities is tantamount to condemnation to a life of perpetual mental dread and unbroken invalidism.

I have intimate knowledge of such a case in a relative of my own.

She was a lady of 58 years of age who had always been delicate, was of the neurotic type, had passed through an anxious and disturbed life, and had comparatively recently come to the end of her menstrual periods. She developed cardiac attacks such as we are now considering, and was kindly, but unwisely, told by her doctor that in one of them she would almost surely die. For close upon three years that she lay in bed afraid almost to breathe. Periodically she experienced an attack of precordial constriction, and on every occasion the members of her family were speedily summoned to see her die. Her life was a living death to her, and to the members of her family her illness was a ghastly nightmare which haunted them unceasingly. Ultimately a course of treatment was suggested which had the effect of improving

a digestion which had been impaired over many years: a spirit of hopefulness was breathed by a wise and optimistic physician into this poor lady's mind, and she eventually recovered, and lived for many years without any return of the heart attacks which an unjustified opinion had led her to regard as her summons to death.

I have lingered over these cardiac conditions at too great length, but it is in the field of heart disease more than any other that the neurotic question becomes, both for the physician and his patient, one of such superlative importance. There is no certain means by which we can be infallibly guided, and, with all the care we can take, the best of us must make mistakes, but my personal experience justifies me in believing that along the pathway of a cheerful prognosis lies the doctrine of comfort for those who, on account of their temperament, are liable to construe out of a hedging opinion the confirmation of their worst fears. I go further, because I believe that, even in the presence of serious organic disease and with the knowledge that a heart is wearing thin, we lighten the remaining days or years of our patient's life, and add to his courage and happiness by keeping alive within him the spirit of hopefulness.

As regards asthma, which may be regarded as the greatest of all the respiratory bugbears of neurotic patients, time will not allow me to do more than glance at it. Asthma may occur under many circumstances, and is frequently secondary to some other disease; but true spasmodic asthma is still a disorder for which no definite organic cause has been found, and it is one which afflicts chiefly those who have inherited or begotten the neurotic temperament. We do not see much of it in our hospital wards, because it is most common among the upper and middle classes of society, where neuroses of one type and another abound. It is, when once contracted, one of the most intractable of all maladies. It does not end fatally, but exhibits a recurrent persistence which makes the sufferer's life miserable and drives him to one doctor after another, then to one quack remedy after another, until he becomes an unbeliever in rational treatment and the slave of "cures." But while all this is true, the point about asthma which in connexion with our subject to-day must not be overlooked is that its manifestations must not tempt us to carelessness. The following case aptly illustrates what may happen.

A man of middle life, who had suffered from ordinary spasmodic asthma since boyhood, came to me after an interval of many years and told me that he had become so tired of the ineffectual attempts of innumerable doctors to cure his trouble that, after consulting many in different parts of the world since I had last seen him, he had, for several years past, trusted to patented medicines of one kind or another. He had also tried almost every climate on the face of the earth, but was unable to assure himself that his attacks were either fewer or less severe in one place more than another. The reason for his present visit to me was that, being accidentally in town, he had been, two nights previously, attacked by an unusually severe seizure, and he thought the excuse a good one for renewing an old acquaintanceship. I remembered him perfectly, and saw but little change in his physical condition. From the long continuance of his asthma his lungs had become emphysematous and obscured the physical state of his heart, but there were no murmurs or other abnormalities so far as could be heard through the noise of his breathing. He assured me that, but for his old asthmatic enemy, he was perfectly well. Fortunately for me, a passing complaint of failing eyesight, which he laughingly attributed to *anno Domini*, prompted me to look into his eyes, and there, to my surprise and regret, I found a marked albuminuric retinitis. This led to an examination of the urine, where full confirmation was forthcoming of an established interstitial nephritis. This patient's asthma was probably still, to some extent, of the paroxysmal type, but added to the old neurosis there was now a renal element of so serious a nature that his days are certainly numbered.

The case is one of the many daily illustrations we get of the need for a routine examination of the urine, but in the bustle of active work, this is an investigation which we are liable to neglect unless there be something in the symptoms otherwise to cause us to fear the existence of kidney mischief.

One more recent experience may be referred to as illustrating an asthmatic difficulty of a different type:

A young lady, who had been operated on ten days previously for the relief of a hydronephrosis, suddenly experienced in the night an attack of breathlessness which gave rise to the greatest alarm. She was distinctly neurotic, and from the day of her operation her digestion had been a source of trouble, with flatulent distension of the abdomen as a leading symptom. The fear was at once aroused that a pulmonary embolism was the

cause of her seizure, and a very guarded opinion was expressed to her friends, but the attack subsided and she experienced no recurrence and developed no subsequent pulmonary symptoms. The absence of pain in the chest made the suggestion of embolism doubtful from the beginning, but, under the circumstances in which the difficulty in breathing arose, the suspicion was justified, though a confident diagnosis either way would have been, at the time, unwarranted.

As in the region of the thorax, so in that of the abdomen, we meet with interesting problems in connexion with disorders of the stomach, intestine, kidney, and liver, and are frequently brought face to face with complex manifestations which demand the most searching clinical investigation to solve correctly. I must defer their consideration to a future opportunity, but in this region of the body as in the others to which I have alluded this afternoon, there is no lack of illustration to prove that the neurotic element in disease is one to reckon with, and that, despite some incredulity on the subject, there is no getting away from the fact that symptoms which are apparently wholly functional dominate the aspect of many illnesses, that they may obscure the true significance of organic manifestations, and that not infrequently they are so much the end-all and be-all of a disordered state of health as to justify the assumption that—at any rate so far as the present state of our knowledge enables us to judge—the neuroses must be taken into account as definite integers in our conception and treatment of disease.

A Lecture

ON THE

TREATMENT OF ECZEMATOUS PATIENTS.

DELIVERED AT THE MEDICAL GRADUATES' COLLEGE
AND POLYCLINIC, LONDON.

By E. GRAHAM LITTLE, B.A., M.D., F.R.C.P.

PHYSICIAN TO THE SKIN DEPARTMENT AT ST. MARY'S HOSPITAL AND
AT THE EAST LONDON HOSPITAL FOR CHILDREN; LECTURER ON
DERMATOLOGY, ST. MARY'S HOSPITAL MEDICAL SCHOOL.

In no affection of the skin is it more important than in eczema to recall the axiom that it is the patient and not the disease that requires treatment; the characteristic which distinguishes the wise practitioner from the quack is that the former realizes that he is in the presence of a sentient human being who is the subject of disease; the latter has merely a nostrum which is applied to the disease with an inevitableness as monotonous as the response of an automatic machine to the insertion of the nimble penny. The title which I have used is intended to emphasize a protest—a more familiar, shorter, and less correct title would be "The Treatment of Eczema"—and my object will be to describe certain common forms of the disease with the methods of treatment which have been found serviceable in each type.

The very first difficulty to be overcome is the exact definition of what is meant by the term "eczema." It is unfortunate that no agreement exists as to what shall or shall not form a criterion of classification; one of the latest of these definitions, that of Dr. Norman Walker—"Eczema is the term commonly applied to any wet or scaly inflammation of the skin of the cause or nature of which the observer is ignorant"—is more humorous than helpful.

The older writers, before our idea of eczema became swamped with the introduction of Unna's "seborrhoeic eczema," insisted chiefly on the presence of "a serous discharge which stiffens linen" as an essential feature of eczema; the same feature distinguishes the phenomenon which recent French authors describe as "eczematization," to which I shall refer again. But, now that there seems a reasonable prospect of the withdrawal from this class of the whole large body of disease at present called "seborrhoeic eczema"—which, as a distinguished writer has tersely put it, is not seborrhoea and not eczema—it is possible that the older simplicity may be restored, and it would certainly make for clearness and be in accordance with the actual practice of a large majority of medical practitioners if the advent at some time or other of "a

serous discharge which stiffens linen" were again to be made the essential criterion of the disease. The presence of such a discharge, however produced, would justify the classification of the affection in which it occurred as eczema; and, consequently, all forms of so-called eczematization and of traumatic dermatitis attended by such discharge would be included in this class. It has always seemed to me a very anomalous and absurd practice to call an inflammation of the skin the result of a known irritant by one name and an inflammation of the skin clinically absolutely indistinguishable in which the cause of the inflammation has escaped observation by another name. This absurd practice is properly satirized in the absurd definition quoted from Dr. Norman Walker's textbook. In my opinion it would be highly desirable—and the time is ripe—to revert to the conception thus excellently defined by Dr. Tilbury Fox:

Eczema is a catarrhal inflammation of the skin which is mainly characterized by a peculiar discharge, stiffening linen, and drying into thin yellow crusts, and having its stages of erythema, papulation, vesiculation, discharge, pus formation and squamation more or less marked under different circumstances, and followed in some cases by the secondary results of inflammation such as hypertrophy, oedema, and the like.

With this conception of the disease as a cutaneous reaction progressively passing through the phases enumerated and with a special tendency, by reason of the discharge, to become secondarily contaminated by pyogenic and other organisms, the apprehension and description of the various clinical variations become much more easy.

Acute Eczema.

This is the name given to an early erythematous eruption occurring with acute onset, generally on exposed surfaces such as the face, and after exposure to cold or irritants. The eruption may be aborted in its erythematous stages, or it may pass on to vesication and subsequent exudation and pus infection of the surface. The erythema when occurring upon parts where the subcutaneous tissues are lax, as on the face round the orbits, may be accompanied by pronounced subcutaneous oedema; the swelling and redness thus produced may closely simulate erysipelas, and acute eczema is frequently mistaken for that disease, from which it is distinguished by the absence of temperature and severe constitutional illness, by a less well demarcated margin between diseased and healthy skin, and often by the presence elsewhere of some patch of older eczema; it is not contagious, so that the history of infection common in erysipelas is absent. The treatment should be prompt and earnest; the possibility, with care, of causing the inflammation to subside without macroscopic vesication—for it is probable that even at this stage there are microscopic vesicles—if explained to the patient, will generally enlist his co-operation in the measures to be adopted, which entail confinement to an equable temperature indoors and the application of the blandest and most sedative lotions. In this stage rest in bed is often the best expedient to secure subsidence of the inflammation. I believe a pure milk diet, partly by its digestibility, partly by the large fluid intake which it ensures, is advisable; and the local application which I have found most useful is the following (lot. plumbi lactatis of the St. Mary's Hospital Pharmacopoeia):

Liq. plumbi subacet.	3j
Acid. sal.	gr. ij
Lactis	3j

This should be freshly prepared, and applied to the face after thorough shaking of the bottle with a clear, soft shaving brush and allowed to dry *in situ*, fresh application being made every four hours. Concurrently with this treatment the bowels should be kept loose, a result which commonly follows from the increased fluid of the dietary, but it may be necessary to ensure the result by saline aperients, of which Carlsbad Sprudel salts (a teaspoonful in a tumbler of hot water every morning) is one of the best. It is a common experience that alcoholic excesses increase the tendency to acute eczema, and the complete prohibition of alcohol is advisable in these cases.

The same type of acute erythematous eczema may occur upon other parts than the face, and must be similarly treated.

When the case is seen in the stage of vesication the possibility of aborting the inflammation is past, and since vesication is almost certain to be attended by pustulation the local treatment to be adopted becomes similar to that detailed under chronic eczema in which those stages are present.

Chronic Eczema.

An attempt has been made to differentiate the so-called artificial eruptions from eczema by the fact that while eczema recurs and becomes chronic, artificial eruptions cease when the cause is removed. But this differentiation is fallacious, for if the cause is constantly renewed the artificial eruption which is its response will also be renewed, and thus chronicity may be simulated. For example, a case noted by Dr. Whitfield of what was diagnosed as "chronic eczema of the mouth" proved to be due to the repeated use of an irritating liquid dentifrice. Many cases of what appear to be chronic eczema are the result of a persistent irritant, and all such causes must be rigidly investigated in any given case. The possibility of constant renewal of external irritation must be particularly borne in mind in the case of persons whose occupations oblige them to come in contact with agents such as chemicals (photographers, druggists, laboratory assistants, operating surgeons, etc.), irritating plants or bulbs, strong detergents (washwomen, kitchen servants), and a large class of persons, such as bakers, cooks, furniture polishers, plasterers, painters, tar and gas workers, who are more obviously exposed to repeated chemical or thermal stimuli. In all such cases it becomes urgently necessary to avoid the pernicious contact if this be possible, especially during the acute stages of the reaction. When this is not possible there ensues a contest between the effects of the irritant and the remedial measures of the physician, in which the latter is not infrequently worsted.

Where no special cause can be identified and removed the conduct of the case becomes more difficult. Some general principles, however, may be enunciated, in the front rank of which I would place a caution not to use strong antiseptics, such as formalin. It is better to proceed gingerly at first with a patient whose cutaneous constitution is still a *terra incognita* to the practitioner. With a freely weeping surface, with much redness and itching, it will be found as a rule that lotions are more sedative and come more into actual contact with the diseased surface than ointments. For such surfaces a common prescription, and one which has done good service with me, is the following (lotio calaminæ oleosa):

Calaminæ	gr. xl
Zinci oxid.	gr. xx
Aq. calcis	3ij
Ol. olivæ	3j

This should be applied with a brush or a swab of cotton-wool, or strips of thin washed "butter muslin" may be soaked in the lotion and kept in position with a light muslin bandage. It is important that the part should not be kept hot, and the covering of an inflamed surface with wads of cotton-wool and several folds of a heavy bandage—a dressing too often resorted to by inexperienced house-surgeons—does not promote the comfort of the patient or the amelioration of the disease. Many practitioners advocate the use of powders in the wet stage of eczema, but my own experience leads me to prefer the formula I have given. When there is much pus infection of the discharge—a very frequent complication—it is often advisable to treat this feature at once, and a very useful means is to steep the part, when its position allows of this, in an antiseptic bath for twenty minutes or half an hour, drying the part carefully after with swabs of dry cotton-wool. The antiseptic used may be varied according to the fancy of the practitioner. I have found chinolol (1 in 200 to 500) unirritating and efficacious; cyllin is also recommended (1 to 200); perchloride of mercury (1 to 2,000 or 3,000) may also be used, or this ingredient may be added to lot. calam. oleosa ($\frac{1}{2}$ grain to 3vj) when an antiseptic effect is particularly desired.

When the discharge has become less free, and the diseased surface, although not dry, has ceased to pour out exudation, the continuous application of a paste is less uncomfortable a means of treatment than the application of lotions. A paste differs from an ointment roughly in the addition to the greasy base of the latter of a consider-

able proportion of an inert powder, which appears to exert a blotting action, on the same principle which is aimed at in the familiar resort to powdered salt to dry a recent wine stain in a table-cloth. One of the most pleasant pastes thus indicated is Lassar's paste. This is often given with varying formulae, and it is well to particularize the composition as follows:

Zinc oxide	24
Starch	24
Soft paraffin	50
Salicylic acid	2

In acutely irritative conditions the salicylic acid is best omitted; it may be retained and the quantity increased when there is less inflammatory reaction, and where much scaling has taken place. An equally good application, perhaps even superior (Cremor zinci, St. M. H.), where there is much redness of the skin, is the following:

Zinc. ox.)	
Aq. calcis)	aa 5j
Ol. olivae)	
Adip. lanæ)	

Dissolve lanolin in olive oil by heat, sift powdered zinc oxide into it, and whip up with lime water.

This may be thickly spread over the affected part, dusted with a fine starch such as potato starch, and left without any other covering than the clean cotton or linen underclothing of the patient.

Other powders used in the composition of pastes besides starch are fuller's earth, talc, kaolin, etc.

If the patient is seen in the stage of dry crusts, when the discharge has matted together the epithelial scales and debris of the surface into an impervious scab, local applications are useless until this is removed. This end may be effected by wet occlusive dressings when the adhesion of the scab is very pronounced—as, for example, on the scalp of children. Several folds of thin muslin, known as "butter muslin"—boiled in water to remove the stiffening used in its preparation and to sterilize it—are soaked in boric acid lotion or in other weak antiseptic fluids, preferably tepid; the excess of the moisture is squeezed out, and the dressing is applied while wet and then covered with oil-silk or protective oiled paper and kept in position with a light bandage. The dressings should be changed as soon as they become dry. Starch poultices, boricated, may be used in the place of this dressing, but are not so free from risk of spreading the pus infection.

A method which I have found very useful in treating the pustular eczema so commonly the result of pediculosis capitis in weakly children is to cover the scalp with an ointment composed of equal parts of olive oil and ung. hyd. am. dil., and enclose the head in an oil-paper cap.

When the crusts have been removed, the application of an antiseptic ointment, such as ung. hyd. am. dil. or ung. hyd. nit. dil., either unmixed or with an equal quantity of ung. acid. sal., will usually check the superficial pus infection and reduce the part to the condition of an uncontaminated exudative or excoriated surface, which may then be treated with lotions or pastes as described above. It is often possible, and is always interesting, to watch under this treatment a successive retrogression in inverse order of the stages by which an erythematous eczematous patch becomes vesicating, exudative, and suppurating.

When the suppuration is not controllable by these methods, and the stage of "chronic pus infection" is threatened, it is remarkable with what good effect vaccine-therapy can be used. The nature of the contaminating organism must be ascertained, and it is preferable that the opsonic index for that organism should be taken before vaccines are used, but even in the absence of an opsonic estimation, an inoculation of the appropriate vaccine may be tentatively made. The dose used should be a very small one; in the case of staphylococcus, which is much the commonest organism thus found to be present, a dose of 20 to 100 millions will usually suffice. The clinical improvement is often striking, and in the event of such improvement the inoculation may be repeated in about ten days' time. The cases in which such inoculations are useful are also eminently those in which general management of the patient is important in the respect of diet, environment, change of air, scene, and occupation, which will be dealt with later on.

Not infrequently patches of inveterate eczema are met with in which individual lesions have persisted for months and even years. In all such cases careful search must be made for some associated cause, such as the presence of ichthyosis, which renders the skin peculiarly liable to become eczematous; of varicose veins; the possibility of the co-existence of constitutional disease, such as gout, diabetes, and tuberculosis, must be borne in mind and investigated. When no such underlying factor is discovered, and when these diseases, though present, are irremediable, attempts may be made to stimulate the growth of healthier epidermis by the exfoliation of the diseased stratum. One of the best methods of achieving this purpose is by the application every four or five days of the following lotion, painted on the part with a cotton-wool swab wrapped round a wooden stick, such as a match or penholder, and dipped into the lotion:

Phenol, liq. picis carb., glycerin, spir. vin. rectif., aa.

In the four or five days' interval between each application the part should be painted three times a day with lot. cal., which should be allowed to dry on the surface. If the carbolic lotion should prove too painful, a 10 per cent. solution of cocaine hyd. may be applied five minutes before the application of this.

A solution of nitrate of silver (10 to 15 grains to the ounce) acts in a similar way and should be used similarly, with the application of lot. calam. in the intervals of treatment. This method is particularly useful for chronic eczema of mucous surfaces, for example, about the anus, the lips, the vulva, the nipple. I have also found picric acid in 1 per cent. or $\frac{1}{2}$ per cent. strength of great service in treating chronic excoriated surfaces, as in pruritus ani with fissures.

Eczema of the nipple, especially of suckling women, is generally kept up by the presence of the milk, which, flowing over the surface, affords an excellent nidus for micro-organisms. An importance which it does not deserve is commonly ascribed to this affection from the erroneous notion that Paget's disease—epithelioma of the breast—begins as an eczema of the nipple. This has been shown not to be the case; the condition which was thought to be eczema has been demonstrated to be epitheliomatous even in the early stage which simulates eczema; the latter disease occurring upon the nipple is often difficult to treat, especially when the patient is obliged to suckle the infant; but once this process is finished the condition usually heals rapidly. Eczema of the vulva may similarly be protracted owing to the discharge over the labia of saccharine urine in diabetes, and the latter disease should be looked for in such cases.

The introduction of zinc into the skin by cataphoresis (ionization) promises a particularly valuable resource in old chronic thickened eczematous patches. A plate of zinc, the size of the patch to be treated, is used as positive electrode of an ordinary galvanic battery of 20 to 30 cells. The electrode is covered with several layers of gauze soaked in a 2 per cent. solution of zinc sulphate, and applied to the patch to be treated, the patient holding in his hand the ordinary cylindrical electrode attached to the negative pole. Contact may be maintained for five to ten minutes, the current averaging 3 to 6 milliamperes during the treatment. For these especially chronic patches x-rays have also been shown to be useful. Some very suggestive experiments have been tried with textile fabrics impregnated with feeble solutions of radium salts, and applied to the surface of eczematous patches with good results.

A method which I have found useful in very chronic dry cases, with much lichenification of the skin, is the combination of occlusive dressings with tar ointment. Strips of lint thickly smeared with ung. picis are cut to the shape of the part, covered with oil-silk and cotton-wool and bandaged tightly over, and left in position for twenty-four or forty-eight hours. The same lint is to be repeatedly smeared with the ointment so that it becomes thoroughly impregnated with it. Under this treatment the resolution of the thickening and the healing of the skin are often very satisfactory.

Eczema of Children.

Young children frequently suffer from eczema of the face and scalp, which is too often ascribed to teething.

the initial microscopic vesicle is demonstrated to be sterile; the later microbic infections are due to secondary contamination of the surface. With these views the importance of the study of the individual becomes enormously increased, and Brocq thus sums up the formidable series of investigations which should be made to elucidate causes of disease other than those of internal source:

"Hereditary pathological states, individual idiosyncrasies, defective alimentation, defective assimilation and excretion, troubles of the venous system, troubles of the circulatory system, troubles of lungs, kidneys, genital apparatus, ductless glands."

Where any such cause can be identified, treatment must be directed to its removal. The hereditary transmission of tendency to eczematous disease, as well as an individual idiosyncrasy, must be accepted by any person of wide experience, and the nature of the cause lifts it beyond the domain of practical therapeutics. Defective alimentation, covering as it does the ingestion of food, has been partly dealt with under the heading of diet; in full-blooded young subjects moderation of the intake of solids will probably be indicated; in the exhausted, impoverished patient of hospital practice, on the other hand, liberal diet and rest are at least as important as any therapeutic measures, as the improvement manifested by admission of such patients to the wards amply demonstrates. Constipation must always be looked for and most carefully avoided, preferably by mild and tonic purgatives. The patient should be weighed at frequent intervals; there is an eczema of the obese as well as of the cachectic, and both are equally obstinate.

The nervous associations of eczema are numerous and difficult to treat. Nervous exhaustion is best met by rest, change of scene and occupation, and the administration of tonics such as combinations of arsenic and iron, strychnine, phosphoric acid, cod-liver oil. It is often stated that sea air is bad for eczema; while it is possible that salt-laden breezes may irritate the eczematous skin, I am convinced by many observations that its bracing effect, especially in the tired town-dweller, on the general constitution counterbalances the local disadvantages mentioned. In other cases where nervous excitability, with vasomotor disturbances, is the dominant feature, sedative measures, such as the administration of bromides, ergotin, antipyrin, colchicum, quinine, belladonna, are indicated; spa treatment in such cases, with its quieting routine, is particularly useful.

Where there is evidence of much oedematous infiltration into the skin, with vivid redness and itching, I have repeatedly found the greatest benefit, especially in children, from doses of calcium lactate, given either in small doses (5 to 15 grains), three times a day before meals, or in large doses (1 drachm), two or three times a week. In the latter method a convenient means of administration is to suspend the powder in milk and drink the latter after vigorous stirring. Calcium lactate should be continued only until the symptoms of oedema and itching have subsided. It tends to produce constipation, and this result must be prevented, preferably by mild laxatives, such as sulphur or senna.

I have touched upon the question of baths when dealing with eczema of children. A general impression, which has acquired the force of a religious belief, has grown up that water is baneful to the eczematous skin, and clearly patients have suffered much misery from the prohibition of washing. The late Professor Lassar, one of the most experienced and successful of dermatological therapists, spent much enthusiasm and energy in trying to subvert this doctrine, with only partial success, for it still lives and flourishes. I am strongly of opinion that this superstition, like many others, has little foundation in fact. It is surely desirable that an eczematous surface, like any other abrasion or wound, should be kept aseptic, and, with proper precautions, washing may be resorted to in any case of eczema and at any stage. The precautions are to use no strongly alkaline or irritating soaps, to use soft water, and more especially to thoroughly dry, not by rubbing, but by "blotting" the moisture off the part, after the immersion, with absorbent wool or gauze.

The question whether a patient should be kept in bed or not will have to be decided by the extent of the disease, the parts attacked, and other considerations. In the

forms where only a small surface is involved and no constitutional illness is apparent, it would, of course, be absurd to make an invalid of the patient. But nothing is more impressive than the difference in the rate of improvement between an in-patient and an out-patient, to be attributed to the greater facility with which dressings can be applied, as well as to the advantages of equable temperature, reduction of the pulse rate and tension, and the diminution of vasomotor disturbances and avoidance of mental activity which rest in bed entails. When the area involved is large the impossibility of keeping the dressings *in situ* in any other position than the horizontal one, will in itself sometimes compel that course. It is, of course, essential that the sickroom should be well ventilated, warm and cheerful, and that opportunities of chill in the change of dressings should be guarded against. Finally, long hours of sleep and avoidance of worry and psychological disturbances are desiderata which are too often "counsels of perfection" for the patient, but which the physician must, nevertheless, make it his business to obtain for him.

THE DISTRIBUTION OF LONGEVITY IN ENGLAND AND WALES.

By W. GORDON, M.D., F.R.C.P.,

PHYSICIAN, ROYAL DEVON AND EXETER HOSPITAL; PHYSICIAN, WEST OF ENGLAND EYE INFIRMARY.

A FEW years ago, in a paper read at Plymouth, I pointed out a simple way of showing the great longevity prevalent in Devonshire by stating, for each registration district, the percentage of the total deaths which is formed by the deaths at 75 and over; and in 1907 I published a table of these percentages for all the registration districts of Devon and Cornwall.

Since then the Registrar-General's decennial report for 1891 to 1900 has become available, and, as local general longevity may affect local general prognosis in many chronic diseases, I thought it worth while to work out these percentages of survivals for the whole of the registration districts of England and Wales. The result is remarkable. Wide differences in local longevity are found to exist in different parts of the country, and it becomes a matter of no common interest to decide how far these differences in percentage mean real disparities in local expectation of life.

The simplest mode of proceeding seemed to be to compare with each other those districts which furnished the highest and lowest percentages (Table I).^{*} It at once became apparent that the highest were found in country districts and the lowest in town districts. Two sources of fallacy then suggested themselves—namely, the large infant death-rates of the towns and the movement of population into the towns from the country.

The first source of fallacy was easily disposed of by recalculating the percentages (for the first ten districts in each column of Table I) after deducting from the total deaths the deaths occurring under 5 years of age (Table II). The contrast between the high and low percentages remained almost as remarkable as before.

The second source of fallacy required more lengthy investigation. Table I gives in parallel columns the highest and lowest percentages amongst the districts arranged in order of numerical sequence, and side by side with each the latest available figures (1881 to 1890) from the Registrar-General's reports relating to (a) density of population expressed in terms of acres to a person, and (b) the decennial increase or decrease of population for the decade 1881 to 1890. In this table it is seen that:

1. All the low percentages are associated with relatively dense populations, and all the high percentages with relatively sparse populations.
2. Most of the low percentages are associated with increasing populations, and most of the high percentages with decreasing populations.

* In the Climatological Section of *A Book of the South-West*, the Handbook of the 1907 Annual Meeting of the British Medical Association.

† The Scilly Islands alone were omitted as, I understand, special arrangements are made there for the emigration of the surplus population.

					Blandford ...	Dorset	25.0	-2.62	4.47

Now, of these two, there need be no hesitation in admitting a causal relation between density of population and percentage of survival. Such a relation is entirely in accord with all we know of the influence of density of population on health, and is borne out by a consideration of its influence on death-rate at successive groups of ages. The point to be determined is whether movement of population has anything to do with apparent percentage of survival.

Since this movement is constantly transferring a mass of young and adult life from the more sparsely populated areas to those more densely populated, it might reasonably be supposed that the differences in percentage were, at least in large measure, due to this movement—and, at first sight, the figures in Table I appear to support this supposition. Indeed, it can scarcely be thought that this movement is altogether without effect. But it has to be remembered that almost all densely populated areas are increasing in population, and that almost all sparsely populated areas are decreasing in population, so that the decennial changes shown in Table I are perhaps no more than should be looked for from the corresponding densities of population.

The following considerations suggest, at all events, that the influence of movement of population on the percentages of survivals is comparatively small.

1. If the columns in Table I are carefully examined marked exceptions are seen to exist to the usual rule of increase or decrease of population, and no clear relation is apparent between the actual percentage of survival and the degree of decennial increase or decrease of the population. (It must be borne in mind, however, that the changes of population given are only for the decennium 1881 to 1890.)

2. The age of 75 is beyond the time of life at which change of residence is usually made.

3. If the death-rates at successive age periods in each district given in Table II be compared, good cause is at once obvious for the higher percentages characterizing the sparsely populated districts. Between 1891 and 1900 the country death-rates were less at almost every age period than the town rates (Table III); and the annexed diagram shows this clearly in the cases of Crediton district (in Devon) and the district of Leeds, neither of these two districts being an extreme example of its class.

4. If we compare in Table I the densely populated districts whose population was either almost stationary or actually declined between 1881 and 1890 with the

TABLE II.—Percentages of Total Deaths over Five Years of Age formed by Deaths at the Ages of 75 and over—1891 to 1900.

sparsely populated districts whose population was either almost stationary or actually increased, we shall scarcely avoid the inference that mere movement of population

makes comparatively little difference to the figures of percentage of survival.

A correction for sex distribution might possibly slightly modify the figures. A correction for age distribution, so

essential in inquiries into the incidence of certain diseases, has appeared to me inapplicable in this particular inquiry.

I would submit that it may be concluded:

1. That there is a very remarkable disparity of longevity in different districts of England and Wales.

2. That this disparity is closely related to density of population.

3. That mere movement of population from country to town, whilst probably tending to make the disparity appear greater than it really is, has on the other hand probably no very considerable effect upon the figures.

THE DIAGNOSIS AND TREATMENT OF SEVERE ANAEMIA.*

By CHARLES H. MELLAND, M.D.LOND., M.R.C.P.,
SENIOR HONORARY PHYSICIAN, THE ARCOATS HOSPITAL,
MANCHESTER.

THE title of my paper is, perhaps, somewhat too extensive for the ground that I shall be able to traverse—a more correct description would be the differential diagnosis and treatment of pernicious anaemia—and since in the diagnosis and treatment the examination of the blood is of crucial importance, I shall have a good deal to say on the features of the blood in pernicious anaemia and in other cases of severe anaemia which may so resemble it as to give rise to difficulty in diagnosis.

The main symptoms of pernicious anaemia are simply those met with in any severe anaemia—great breathlessness on slight exertion, faintness or actual syncope, great muscular weakness, and palpitation of the heart. All these may be present in severe anaemia from whatever cause, and are in no way characteristic of pernicious anaemia, but there are certain other features which may be present, though by no means always so, which afford further clinical evidence of the disease. These are the peculiar yellow colour of the skin, suggestive of a slight

degree of jaundice; the presence of numbness and tingling in the hands and feet, the result of the lesions in the peripheral nerves and spinal cord, which are almost always found if these are examined *post mortem*; and the presence of small ulcerations and red patches about the tongue, lips, and gums, of soreness in the oesophagus and stomach, vomiting, and occasional attacks of diarrhoea, with the passage of pale, clayey and sometimes frothy stools. These symptoms of an infection of the alimentary tract are not always present, but if present they are most characteristic.

There are many conditions which may give rise to anaemia so profound as to bear a close clinical resemblance to pernicious anaemia. It would be impracticable to refer to them all, but the most important among them are these:

1. Diseases of the haemopoietic and lymphatic system, as leucocythaemia—spleno-medullary, lymphatic, or, more particularly, acute; Hodgkin's disease; leukaemia, a condition probably closely allied to acute leucocythaemia; and primary aplastic anaemia.

2. Carcinoma of the stomach.

3. Repeated small haemorrhages.

4. Long-standing cases of septicaemia, in particular ulcerative endocarditis.

5. Severe chlorosis.

6. Chronic Bright's disease.

7. A number of secondary causes of severe anaemia, scurvy, malaria, syphilis, phthisis, infection of the intestine with *Bothriocephalus latus* or *Ankylostomum duodenale*.

All these conditions may cause severe anaemia which clinically closely resembles pernicious anaemia and accordingly they must be carefully borne in mind in examining a suspected case. It is a fatal tendency to place too sole a reliance on the blood examination. The examination may prove to one's satisfaction that a patient is suffering from pernicious anaemia, or it may as conclusively prove that he is not, but in this latter case the cause of the anaemia remains in doubt unless one has made inquiries as to other possible causes. So that when making the blood examination one must at the same time examine for any evidence of carcinoma of the stomach or for any history of haemorrhage, and a common form of the anaemia from haemorrhage is that which follows compara-

* An address to the Manchester Medical Society, November 4th, 1908, illustrated by a lantern demonstration of photomicrographs of the blood.

tively small but frequently repeated losses of blood from piles. Evidence of chronic septicaemia must be sought for and the heart examined, in the recollection that ulcerative endocarditis is very insidious in its onset, and that its symptoms frequently point to anywhere else other than the heart as the site of the mischief. Then the urine should be examined for albumen and other evidences of chronic nephritis, a condition which not uncommonly reveals itself by no other symptoms but those of anaemia. Other causes, with, as a rule, fairly obvious signs, such as soury, malaria, syphilis, and phthisis, must be borne in mind and examined for at the same time. Nor must it be forgotten that severe chlorosis may closely resemble pernicious anaemia, and that it may be met with not only between the ages of 18 and 25, but occasionally in older women, particularly in those that have suffered from it in their earlier years.

If, on a careful examination, none of these causes of severe anaemia can be recognized at present, there is a presumption that we have to do with a case of pernicious anaemia, but conclusive evidence can only be gained through the blood examination.

Blood Examination.

In pernicious anaemia the red corpuscles are greatly reduced in number; instead of 5,000,000 or more in the cubic millimetre we find only 2,000,000, 1,500,000, or they may be reduced to 1,000,000 or lower; that is to say, that there are only 40, 30, or 20 per cent. of the normal number of corpuscles. The haemoglobin is also reduced, but not to the extent that the corpuscles are; in a patient with 1,500,000 corpuscles (that is, 30 per cent. of the normal number) there may be 40 per cent. of haemoglobin, and the fraction formed by putting the percentage of haemoglobin above that of the red corpuscles is greater than unity, in the case supposed being $\frac{40}{30} = 1.33$, which, differently put, reveals the fact that each corpuscle contains 133 per cent. of the normal amount of haemoglobin, this figure, expressed either in relation to unity or per centam, being known as the haemoglobin index. The leucocytes are almost as constantly diminished from the normal 8,000 down to 2,000 or 3,000 or less in the c.mm., and as this reduction is almost solely confined to the polymorphonuclear neutrophils there is a relative excess of lymphocytes, these cells forming 60 to 70 per cent. of all the leucocytes present, instead of normally 15 to 20 per cent. On examination of stained films of the blood the most notable feature is the great diversity in the size and shape of the red corpuscles. There are many larger than normal, macrocytes, and, indeed, the average size is larger than normal, in keeping with the fact that each corpuscle contains, on an average, more than 100 per cent. of haemoglobin. The diversity in shape is an equally marked feature. In a normal blood the corpuscles are all approximately equal in size and with a correct circular outline, but in pernicious anaemia round corpuscles are in a minority, the majority are oval or elliptical or pear-shaped, or still more irregular—poikilocytes. We find, further, changes in the staining capacity of the red corpuscles, some are polychromatophilic—that is to say, they show an affinity not only for the acid eosin stain, as is normal, but also for the basic methylene blue, and so appear greenish or bluish; whilst some show the presence of granules which stain with methylene blue, the so-called "granular degeneration," or basophile stippling of the erythrocytes. In addition we may find nucleated red corpuscles, though I am inclined to lay much less stress upon them than upon the other features I have mentioned, and it is particularly the finding of the variety described as megaloblasts which is of such significance. Nucleated red corpuscles are not uncommon in many conditions of severe anaemia, but these are mostly normoblasts, corpuscles of about normal size, shape, and staining capacity with a small deeply staining nucleus. The megaloblasts which are met with in pernicious anaemia and in leucoerythraemia are very different looking cells, and are characterized by three typical features—namely, the large size of the corpuscle, the large nucleus with well marked nuclear network, and the cytoplasm showing very decided polychromatophilia.

Now let us turn to the characters of the blood in some of these other forms of severe anaemia that I have referred to. The more chronic forms of leucoerythraemia only occasionally present any high degree of anaemia; and in

addition they present certain clinical features, the great enlargement of the spleen in the spleno-medullary form and of the lymphatic glands in the lymphatic form, which suggest the nature of the disease. A single glance at the stained film clinches the diagnosis, the great increase of leucocytes is at once apparent; a large proportion of these, 25 to 40 per cent., in the spleno-medullary form being myelocytes with a large single nucleus and neutrophile or eosinophile granules, whilst in the lymphatic form the great majority, well over 90 per cent., as a rule are lymphocytes. Acute leucoerythraemia requires more circumspection. The anaemia is usually most profound, and not uncommonly there is no enlargement either of spleen or lymphatic glands, and it is impossible to pronounce for certain about a case until the blood examination is made, and in the absence of such examination there is little doubt that cases frequently go undiagnosed. But the appearance of the film is conclusive, and we find large numbers of lymphocyte-like cells, the larger forms usually preponderating. Of leukaemia I need say little; it is an uncommon, and as yet not quite clearly defined, condition. There is most profound anaemia, and the blood, while in many ways resembling pernicious anaemia, as in the high haemoglobin index, and the large average size of the corpuscles, bears also some resemblance to that in leucoerythraemia. Though there may be no increase in the number of leucocytes (at times even a decrease), there are qualitative changes, consisting in the presence of a considerable proportion of myelocytes or of the large "lymphoid" cells that are met with in acute leucoerythraemia, which distinctly bring it into the category of leukaemia-like diseases, and at times the number of leucocytes may greatly augment, so that the blood comes to be indistinguishable from a case of acute leucoerythraemia.

Apart from these special conditions, the other forms of severe anaemia I have enumerated all show practically uniform blood changes which are on the whole the antitheses of those met with in pernicious anaemia. The red corpuscles are rarely reduced to the extent that they are in pernicious anaemia while the haemoglobin is proportionately more reduced than the corpuscles, giving an index of below 100, very often far below. The average size of the red corpuscles is smaller than normal, instead of being larger, and there is comparatively little variability in size or shape. Nucleated red corpuscles are less numerous; if present they are of the normoblast type, megaloblasts being practically unknown, whilst those which show polychromatophilism or granular degeneration are infrequent, except the latter in lead poisoning. I may say parenthetically that the anaemia of *bothrioccephalus* infection is an exception to this type. I have never seen a case, but the blood is said to be indistinguishable from that of pernicious anaemia, and the diagnosis depends on the discovery of portions of the worm or its ova in the faeces.

Let us consider one case, that of a man with severe anaemia, the result of long-standing loss of blood from bleeding piles. His haemoglobin was down to 28 per cent., a more profound anaemia than in most cases of pernicious anaemia. But the corpuscles were proportionately much less reduced, being 2,700,000, so that the haemoglobin index was as low as 52, each corpuscle containing barely half the normal amount of haemoglobin, whilst the corpuscles in the stained film appeared small and washed out, but fairly regular in size and shape. Another man had all the appearance and symptoms of a case of pernicious anaemia, and took his place among the patients at a university examination as such. But on examination the haemoglobin was found to be 20 per cent. and the red corpuscles 2,570,000, giving an index of 52, and the stained films showed all the characters of a secondary anaemia, and none of pernicious anaemia. I felt very strongly at the time that the slight gastric symptoms which he showed, and which had naturally been looked on as the gastric symptoms of pernicious anaemia, were due to carcinoma of the stomach—a surmise which subsequently proved correct, and was verified *post mortem*.

Occasionally in cases of secondary anaemia one sees so great an irregularity in size and shape of the red corpuscles that at a first glance a diagnosis of pernicious anaemia is suggested. In one such case, however, the index was found to be only 74, and a more critical examination of the film showed that the average size of the corpuscles was in keeping with this low haemoglobin index—decidedly below the normal—and so the superficial resemblance to pernicious anaemia vanished. Very occasionally one may get a few true macrocytes, as in one case of severe

anaemia from carcinoma at the cardiac orifice of the stomach. Here there were occasional enormous red corpuscles that would have done credit to any case of pernicious anaemia, and others that were distinctly above the normal size. But these were exceptions, and the average size was much below normal, in keeping with a haemoglobin percentage of 18, a red count of 1,560,000, and a haemoglobin index of only 57 per cent. Even in a typical case of chlorosis I have come across large numbers of macrocytes, which at first sight strongly suggested pernicious anaemia, but the other corpuscles were small, and, in spite of the number of large corpuscles, the average size was below normal, as shown by the low haemoglobin index of 64.

Prognosis and Treatment of Pernicious Anaemia.

There is much error in regard to the prognosis; the disease is too commonly looked upon as inevitably and speedily fatal, and so no proper steps are taken to ensure adequate treatment. Now, although I do not for a moment deny the seriousness of the disease, it is my experience that no other of the more serious diseases responds so satisfactorily to prompt and efficient treatment; and that if recognized early some cases may be actually cured, while others may have several years of fairly comfortable life ensured to them.

Take, for instance, a case whom I have under my care in August, 1903. Her lowest red corpuscle count was 1,570,000 and the blood at that date had all the typical characters of pernicious anaemia. After two and a half months' treatment the red corpuscles had risen to 5,064,000 per c.mm., the haemoglobin was 92 per cent, and there was absolutely no abnormality to be detected in the corpuscles. I have had her under me since then from time to time and she has shown no sign of relapse.

Another case had only 1,210,000 red corpuscles in the c.mm. when he was admitted into the infirmary under Dr. Dreschfeld in 1899, and was in every way a typical case of pernicious anaemia. After five weeks' treatment his corpuscles had risen to 3,560,000 and had almost lost their irregularity in size and shape, and two and a half years later, when he was under my care at the Ancoats Hospital, they had risen to 4,180,000 and in appearance were perfectly normal. He died in 1906, but from consumption, not from pernicious anaemia.

Now as regards the details of treatment. Ever since Byrom Bramwell first demonstrated its value arsenic has been our sheet-anchor in pernicious anaemia. The mode of giving it is of the greatest importance. It is quite useless to give 2 or 3 minims of liq. arsenicalis as is too often done in a perfunctory fashion. It must be started at 4 or 5 minims three times a day and rapidly run up by increments of 1 minim per dose every day or every other day to a dose of 12, or, if possible, 15 minims. When these large doses are being approached, the blood should be again examined, and, if improvement is commencing, the dose should be dropped, and then again increased. The reason for this is that if improvement has started there is less need to push the drug and greater need to avoid setting up toxic symptoms, which might entail its being wholly stopped for a while, with consequent liability to relapse. I have emphasized this point particularly, because I have on more than one occasion had this account given me on asking a doctor how a patient that he had sent to me had gone on: "That he had gone on splendidly for some weeks with the continued full doses of arsenic, but then he had shown toxic symptoms, the arsenic had had to be stopped entirely, and he had rapidly gone to pieces." Of course, if the second examination of the blood shows no commencing improvement, the arsenic must still be pushed, and, in the hope of its eventually proving effective, the risk of poisonous effects must be taken. One is between the devil and the deep sea.

The natural history of a case under such treatment usually is that he improves rapidly after he has once started to pick up, gives up treatment, and before long relapses, and the successive relapses which may occur are usually each more severe and more difficult to cure than their predecessors. He feels so well as the result of treatment that nothing will convince him that he is not permanently cured, and too often his doctor falls into the same belief and sends him off for a long holiday, with most dire consequences. It is of the utmost importance that the patient should keep on with small doses of arsenic, even though feeling perfectly well, that he should never go longer than ten days or a fortnight without being seen by his doctor, and that if there is any suspicion of a

commencing relapse a blood examination should be at once made, for the relapses, if detected early, may respond readily to treatment, but if overlooked (and their onset is nearly always most insidious) they prove more stubborn than the previous attack.

There is another line of treatment which may be combined with the arsenical, based on Hunter's theory that the essential cause of the disease is a chronic oro-gastro-intestinal infection. The removal of carious teeth, the use of antiseptic mouth washes and of gastric and intestinal antiseptics should never be neglected. Various internal antiseptics may be used. I have mainly employed salol, beta naphthol, mercury perchloride, and petroleum emulsion. The same rule applies to these as to arsenic—they should be continued in small doses during the well periods and in full doses on any suspicion of relapse.

Finally, I should like to say a word about the use of red bone marrow in the treatment of pernicious anaemia. I had seen so many cases in which various extracts had been used with absolutely no good result that I not unnaturally became very sceptical as to its value. Its use, too, was advocated on an imperfect analogy with the use of the thyroid substance in myxoedema. The action of the thyroid gland is a chemical one, and its secretion is a chemical product, but the action of the bone marrow in producing the blood cells is a purely vital one, which must cease as soon as its cells are dead. But comparatively recently Dr. Gullan has published some cases in which its use appears to have been effective. He suggests that in addition to the vital process of reproduction of red and white cells which goes on in the bone marrow there may be a chemical process—the production of an internal secretion. He supposed that when the red bone marrow is administered this internal secretion may be such as to stimulate the vital production of blood corpuscles in the patient's bone marrow, and also that it may act, as there is some experimental evidence to show that arsenic does, by increasing the resistance of the red corpuscles to the action of the haemolytic toxins which are looked on as the cause of the disease. Consequently I tried the effect of the red marrow on two cases, old standing cases, one of whom had been suffering for at least four years, and had relapsed several times. Both were proving resistant, as is the way with relapses, to the arsenic and antiseptic treatment, and I can say that the more rapid improvement in both dates from the addition of the red marrow to their dietary, and one, the worse of the two, has now kept well for six months on no other treatment, though I cannot say how long the improvement is likely to last. At any rate, I believe that combined with other methods it is one which should not be neglected.

PERNICIOUS ANAEMIA WITH PIGMENTATION OF THE SKIN AND BUCCAL MUCOUS MEMBRANE.

By JOHN AITKEN, M.D., Ch.B., GLASC.,
ASSISTANT PHYSICIAN, KILMARNOCK INFIRMARY.

THESE notes on two cases of pernicious anaemia which were under observation about the same time appear to me to be of interest on account of the unusual site of the pigmentation in the first case, and the early appearance of glossitis as a symptom in both.

CASE I.

H. F., aged 52, a baker, was first seen on October 14th, 1908, complaining of general weakness of about five months' duration.

History.

Family history was unimportant and personal history good, he having had no illness of importance since childhood. There is a history of alcoholic excess at intervals over many years; he is a moderate smoker and has had no venereal disease.

Except for occasional attacks of biliousness—gastric discomfort and flatulence—he has always had good health. In May, 1908, he was able to carry on his business, which entailed early rising and long hours, without undue fatigue, and felt quite well. In the beginning of June he had an attack of diarrhoea without stomach disturbance after eating a quantity of new potatoes, and to this he attributes his present illness. The attack lasted two or three days. Some time afterwards he noticed that he had to take any exertion more leisurely on account of shortness of breath, and that his feet were slightly swollen at night. He suffered from pains in the legs at this

time, and occasionally noticed purple spots over his shins. During July the breathlessness became marked, and his friends commented on it and on his pallor. He became aware also of a decided loss of energy, feeling "done up" after his day's work, and of an excessive sleepiness. Owing to increased weakness and giddiness he had to shorten his hours, and finally by the middle of August to give up work altogether, as he had sometimes to be assisted home after fainting attacks. While his appetite and digestion seemed good, he has had at intervals, causeless and painless attacks of diarrhoea which ceased in a few days on a strict milk diet; and, occasionally, since the onset in June, a sore mouth and tongue which made chewing very painful. On each occasion he has "cured" this with borax and honey, and for the past six weeks it has not troubled him. For the last two months he has been mostly in bed; at times able to get up and go out; at others, shivery, languid, and liable to faint if he raises his head from the pillow. He has not been able to rise for two weeks past. His present complaint is of weakness and distressing noises in the chest and ears. He has never had pain in the stomach nor vomited. There is no history of any hæmorrhage.

Condition on Examination.

He is a well-built, muscular man, inclined to stoutness, but with no sign of wasting. Expression is languid. Face is extremely pale and pigmented (see below), and skin over the rest of the body is slightly yellow in tint. Mucous membranes are of a dull white colour, and the ocular conjunctiva is slightly yellow. Temperature is 100° F.; pulse 110, regular and very compressible. Tongue is clean, pale, flabby, and unusually smooth. All the teeth are gone, except two incisors, two canines, and four molars, which are blackened and carious. Pupils are equal and normal. There is slight oedema of the chest wall, dorsum of feet, and eyelids, and tenderness on pressure over sternum and long bones. The slightest exertion, such as sitting up in bed, brings on a violent thumping pulsation over cardiac area, especially noticeable in the epigastrium, and evident in the vessels of the neck, and this pulsation he hears painfully distinctly. The area of cardiac dullness is slightly increased to the right, and a soft blowing V.S. murmur is heard distinctly at the apex, less distinctly at base. Second pulmonary sound is accentuated. At bases of lungs behind there is deficient resonance to percussion, and a few fine moist râles are present. There is very marked dyspnoea on movement. Liver dullness extends about 1 in. below the costal margin, and the edge can be palpated there. It is not sensitive to pressure. Spleen is not enlarged, and there are no enlarged glands. Abdomen is relaxed and soft, and nothing abnormal can be detected there.

Urine is high coloured, acid, and specific gravity is 1018. A faint trace of albumen is present, but no casts. Knee-jerks are active, and plantar and superficial reflexes normal. Sensation appears to be undisturbed.

Fundus Oculi (Dr. Arthur J. Ballantyne).—There is abnormal pallor and transparency of the blood in the retinal vessels. In both fundi there are numerous flame-shaped hæmorrhages and several soft-edged exudative patches. Some of the hæmorrhages have the pale centre, sometimes described as characteristic of the hæmorrhages of pernicious anaemia.

Blood examined on October 14th showed red corpuscles 1,230,000 (24 per cent.) per c.mm.; hæmoglobin, 32 per cent.; index, 1.35; and white corpuscles, 5,500 per c.mm. The most noticeable feature in the stained slide was the very large size of a great number of the red cells, and on measurement 40 to 45 per cent. of them were over 9 μ . Most showed a tendency to oval in shape, and only a few were circular. There were numerous poikilocytes and microcytes. Polychromatophilia was marked, many of the red cells staining grey, brown, or purple in whole or in part (Ehrlich-Biondi stain). Polymorphonuclear leucocytes were diminished in numbers to 50 per cent., and a small percentage of neutrophilic myelocytes was present. Nine megakaryoblasts and two normoblasts were seen in differentiating 1,000 leucocytes.

On the arms and legs and lower abdomen, and to a lesser extent on the face and neck, a marked pigmentation of the skin is present. Over the face and neck pigmented patches are distributed, pale grey to pale brown in colour, with a distinct edge and irregular outline, but clearly marked off from the surrounding very pale skin. Similar patches are present on the lower legs, dorsum of feet, forearms, and backs of hands, and in those situations are of a dark brown colour. Scattered over those surfaces are also a number of discrete spots, light brown to chocolate in colour, varying in size from a pin's head to a sixpence, and mostly of circular outline. They are not elevated. Over thighs, flanks, and lower abdomen the skin presents a mottled appearance, due to the presence of a large number of discrete pale brown spots about the size of a lentil.

Blood Examinations (Case 1).

	Red Corpuscles.	Hæmoglobin.	Colour Index.	White Corpuscles	Neutrophils.	Small Lymphocytes.	Large Lymphocytes.	Eosinophiles.	Basophiles.	Myelocytes.	Megakaryoblasts.	Normoblasts.	No. Differentiated.
October 14...	1,230,000	32%	1.33	5,500	50.1%	39.8	3.8	4.7	0.1	1.5	9	2	1,000
October 22...	935,000	28%	1.5	—	51.7%	42.7	2.3	2.1	0.2	0.9	7	0	1,000
October 24...	614,752	20%	1.6	5,000	50.1%	47.0	2.0	0.4	0.0	0.5	22	1	1,000

A few spots are present on the front of the chest. There is no pigmentation of axilla or nipples.

Pigment spots are also present on the buccal mucous membrane, situated on the palate, lips, and cheeks; on palate and lips being symmetrically placed, on cheeks irregularly and where the teeth are absent. They are thirty in number, the smallest being the size of a pin's head, and the largest $\frac{3}{4}$ in. by $\frac{1}{4}$ in. The colour varies from a light patchy brown to a deep homogeneous chocolate; they are irregular in outline, but have a distinct edge. The spots are not raised, nor affected by pressure, nor sensitive to touch.

On the ocular conjunctiva on the upper surface of the globe, situated at the extremity of the vessels, are dark, opalescent spots about the size of a pin's head.

There were no signs of hæmorrhage on the mucous membranes or skin.

The patient could give no definite information about the spots on his skin, except that they had "become much worse lately."

After-History.

The patient became gradually weaker, though he had periods of apparent improvement, alternating with periods of apparent collapse. Temperature was irregular till he died, varying from 99° F. to 101° F., but never normal. Dyspnoea (which was not affected by posture) was very marked, and palpitation troublesome. On October 20th red corpuscles were 935,000 per c.mm., and hæmoglobin 28 per cent. On the 21st he fainted on attempting to get out of bed; vomited considerably, and for the next two days was hardly able to move. On the 24th, he again fainted on attempting to rise. Red corpuscles were 614,752 per c.mm., hæmoglobin rather under 20 per cent., and he had to be punctured several times before enough blood could be got to fill the pipettes. On the 25th he was unconscious all day, bowels and bladder acting involuntarily. Next morning he was sitting up in bed, having partaken of bread and porter. In the afternoon he became comatose, and remained so till he died, twelve hours later. Post-mortem examination was refused.

CASE II.

Mrs. H., aged 65, was seen in November, 1908, complaining of general weakness, giddiness, and palpitation, of eight months' duration.

History.

She had a history of ten years' indifferent health, having suffered from anaemia and shortness of breath, but otherwise no definite illness till two and a half years ago. Then, following a "sore tongue," she suffered from attacks of diarrhoea, and became gradually very weak, pale, and breathless. She was in hospital (August, 1906) for a time, and left much better. A similar turn took place in 1907; she was again in hospital, improved, and was better for some months. Eight months ago weakness and breathlessness gradually increased again; and since then she has suffered from bilious attacks (without vomiting or pain), which frequently left her skin yellow. These attacks were followed often by diarrhoea, and occasionally accompanied by a sore tongue. During the last month she has been completely confined to bed on account of weakness. There is no history of hæmorrhage. There is a history of alcoholic excess for some years.

Condition on Examination.

The skin was lemon yellow in tint and ocular conjunctiva was slightly yellow. There was no marked wasting. There was slight oedema of the eyelids, pulse was 100, regular and soft, and temperature 99° F. Teeth were mostly absent and remainder carious, and the gums were spongy. Tongue was slightly furred, and on the left side of dorsum and tip a shallow ulcer, 1 in. by $\frac{3}{4}$ in., with red edges, and very sensitive to the touch, was present. Cardiac dullness was normal and a V.S. murmur was present all over the cardiac area. Liver was slightly enlarged, and the spleen could be palpated. There was tenderness to pressure over the stomach. Urine was pale, with a specific gravity of 1016, and contained a trace of pus. Knee jerks were active and superficial reflexes normal. Blood examination showed red corpuscles 1,800,000 to 1,650,000 per c.mm., hæmoglobin 50 to 45 per cent., index 1.6 to 1.5, white corpuscles 4,400 to 5,400 per c.mm. More than 50 per cent. of the red corpuscles were over-sized. Poikilocytosis and polychromatophilia were marked. Differential count gave neutrophils 42.5 per cent., small lymphocytes 45.7 per cent., large lymphocytes 9.7 per cent., eosinophiles 3.2 per cent., myelocytes 0.7 per cent. Two megakaryoblasts were seen in counting 400 leucocytes on one occasion, three on another, but no normoblasts.

A slight degree of pigmentation of the skin was present. On the face and neck, arms and backs of hands, legs, thighs, dorsum of feet, and lower abdomen small pale brown spots, fairly circular in shape and about the size of a lentil, were

distributed. On exposed surfaces the spots were darker brown in colour. There was no pigmentation of nipples, axillae, or mucous membranes.

These cases present some features of interest. The entire duration of Case 1 from the onset of distinct symptoms was five months, and the course, though showing the peculiar periodicity of the disease, was typically "progressive." Hunter¹ states those acute cases are the rarest form, and Cabot,² in an analysis of 1,200 cases, found 14 per cent. progressive. The patient definitely dated the onset to an attack of diarrhoea—in itself, as a cause, out of all proportion to the anaemia that followed—and his only previous complaint was of biliousness. It is interesting to note that he made no complaint of a sore mouth until particular inquiry was made on that point, though it had given him considerable pain and he had had recourse to treatment for it frequently. Both diarrhoea and glossitis appeared—according to his statement, when he was "quite well"—before any definite symptoms of anaemia had developed, and both recurred frequently during the course of the illness. In the second case the patient attributed the onset voluntarily to a "sore tongue" followed by diarrhoea. She had been anaemic for some years previously, but after this attack of diarrhoea her condition became rapidly worse. From her history she has had two relapses, and in each the gastro-intestinal symptoms were early and periodic.

These cases appear to me to agree with Hunter's conclusions. As a result of his prolonged experimental, pathological, and clinical inquiries he holds that pernicious anaemia is not merely a special form of anaemia, but that it is a specific entity. "The primary etiological factor is a specific haemolytic infection, giving rise to a specific infective glossitis, gastritis, and enteritis, with sepsis of the alimentary tract, as a potent predisposing factor." "A definite, specific, haemolytic, infectious disease, localized to the alimentary tract, with characteristic mode of onset, clinical features, and course; haemolytic and infective lesions."³

The appearance and symptoms of Case 1 at first suggested Addison's disease. The typical lemon-yellow tint of the skin was nowhere present, and the pigmentation of the face to some extent obscured the extreme pallor. N. S. Davis,⁴ writing on Addison's disease, says "the symptoms of pernicious anaemia are so much like those of Addison's disease that the former might be suspected until the characteristic pigmentation appeared on some part of the surface"; and other writers refer to a possible confusion. In this case the widespread pigmentation of the skin, the presence of well-marked pigment spots on the buccal mucous membrane, with progressive asthenia, gastro-intestinal symptoms, and a tendency to syncope, made a diagnosis doubtful until the blood examination revealed the characteristic changes of pernicious anaemia, and further inquiry brought out the suggestive points in the history.

Pigmentation of the skin is an unusual feature in pernicious anaemia, and most of the textbooks do not refer to its occurrence. Cabot, in his analysis above referred to, found in 38 cases mention of a "brownish tint of the skin resembling sunburn, and usually attributed to overdosing with arsenic." Case II was possibly of this nature, as she had arsenic frequently and over long periods; but the resemblance of the spots in appearance and situation to those in Case I is suggestive. In Case I the administration of arsenic as a cause could be definitely excluded. A number of similar cases have been reported. Laache⁵ noticed a dirty yellowish discoloration of the skin in several cases, which recalled Addison's disease; and Immerman⁶ reported two cases in which a well-marked bronzing of the skin developed. Packhard⁷ has reported a case in which areas of pigmentation were present over the face and body, with areas of leucoderma, and quotes Broadbent⁸ as having described a similar case. Decastello⁹ has reported three cases, in one of which the pigmentary changes corresponded with sensory nerve areas; and Fortune¹⁰ a case in which well-defined brown patches and brown spots were present over body and limbs. It is noteworthy that in the cases which came to necropsy (Laache, Immerman, Fortune) the suprarenal capsules were found normal. On the other hand, Stanley¹¹ has described cases of anaemia (pernicious?) in which pigmentation of the skin occurred and in which at

necropsy there were marked changes in the suprarenal bodies.

With the exception of its presence in Addison's disease, buccal pigmentation does not appear to be of common occurrence. It has been reported as having been found, without any very evident cause present, in chronic gastric conditions; in abdominal conditions (Schultze¹²); in Graves's disease (Sibley¹³). It does not seem to occur as a result of the prolonged use of arsenic.

With regard to its occurrence in pernicious anaemia, I have found very little reference in the literature. Hale White¹⁴ showed a case of pernicious anaemia with pigmentation in the buccal mucous membrane at a meeting of the Association of Physicians of Great Britain and Ireland (May, 1907) of which I have seen no report. Lazarus¹ reports a case in which "on the tip of the tongue and on the mucous membrane of the cheeks, were circumscribed reddish-brown, mahogany-like discolorations, of punctate to dime size, which were undoubtedly the sites of hyperaesthesia, and probably represented haemorrhages into the mucous membranes."

In the present case the spots were on the palate, lips, and cheeks, but absent from the tongue; insensitive to touch; and no signs of haemorrhage were observed.

TWO CASES OF CARDIAC DISEASE.

By W. BLACK JONES, M.D., B.S. LOND., D.P.H.,

PHYSICIAN TO Llangammarch Wells Spa.

THE following notes of two cases of cardiac disease who were under my care at Llangammarch Wells, during the summer of 1908 may be of interest.

CASE I.

A youth, aged 16, who had had a weak heart for several years. His history showed that he had scarlet fever at the age of 6 years, and he also had subsequently several attacks of influenza. In 1902 he had a severe fainting attack, and consulted a specialist, when a cardiac lesion was first observed. A short time before his arrival at Llangammarch he had evidently strained himself by running when at school.

When I saw him in July he was somewhat feeble, being thin and tall; his height was 6 ft., and his weight 9 st. 3 lb. The heart was considerably enlarged. At the apex, which was in the nipple line, the sounds were normal, but at the right base there was a systolic murmur, which was also heard behind. The pulse was regular, 72, and the tension 130 mm. by Poise's manometer. There was extensive granular pharyngitis.

He was placed on a strict course of treatment, which he carried out very faithfully. He drank a glass of barium water three times daily, and he had daily either a barium bath or massage. At the commencement he was, owing to his feeble condition, restricted in his exercise, but after a short time he was encouraged to undertake a little hill climbing. His diet was carefully regulated, and he had a short rest every afternoon. The pharyngeal granulations were destroyed by the galvano-cautery.

He soon began to improve; he gained in weight and strength, and was able to ascend a fairly steep hill slowly without any marked acceleration of the pulse, and without any signs of dyspnoea. This treatment, after the method suggested by Certei, I find to be of considerable value, and at Llangammarch there are special facilities for carrying it out. It is only used in selected cases.

After six weeks' treatment I found the patient much improved; the area of cardiac dullness had diminished, the apex beat now being distinctly felt half an inch inside the nipple line.

I heard from my patient a few weeks ago, and he reported that he felt very well, had gained in height, and had no cardiac symptoms to trouble him.

CASE II.

A young man, aged 19, had had rheumatic fever at the age of 11, and a second attack in 1907. He was also subject to chorea.

He was anaemic, he stooped considerably, and breathed chiefly through the mouth. The chest was flat, the area of cardiac dullness enlarged, the apex being in the nipple line, where there was heard a loud systolic murmur, which was conducted outwards and heard behind. The pulse was regular, the rate being 68 and the tension low. There was no dyspnoea

and no pain, but he had palpitation occasionally. At times there were slight choreic movements of the facial muscles, and also of the left arm and leg. There was considerable obstruction in the nasal passages owing to hypertrophy of the lower turbinate bodies.

He was placed on a course of general treatment similar to that mentioned above. The mucous membrane of the lower turbinate bodies was cauterized in several stages. After a few weeks he was able to breathe entirely through the nose, and ceased oral respiration. He made good progress, his palpitation ceased, and he was able to take walking exercise with ease and without discomfort. In addition to the balneological treatment I am convinced that the removal of the nasal obstruction had a marked effect in relieving the heart from obstruction in the pulmonary circulation.

A few days ago his medical attendant reported that he had no trouble with the heart and looked very well. The murmur was still present, but the pulse was regular, the rate being 68. He had increased in weight and had no dyspnoea.

One object of the treatment is to train the patient as to the amount and nature of the exercise he may take with benefit, and this forms a valuable guide to him when he returns to his ordinary life.

In conclusion, I should note that the mineral water, besides barium chloride, contains a considerable amount of calcium chloride, which recent observations have shown to have a somewhat similar action—that is, in slowing the pulse and increasing the force of the systole.

CASE OF GENERAL PARALYSIS OF THE INSANE WITH EXTRAORDINARY LYMPHOCYTOSIS IN THE CEREBRO-SPINAL FLUID.

By WILLIAM BOYD, M.B., Ch.B.,
HOUSE-PHYSICIAN, EDINBURGH ROYAL INFIRMARY.

It is now generally recognized that in tabes and general paralysis of the insane the cerebro-spinal fluid usually—perhaps always—contains an excess of lymphocytes, and that this lymphocytosis may be of considerable value in

exact number could not be estimated. In the non-centrifuged cerebro-spinal fluid the number of leucocytes (almost all lymphocytes) was no less than 285 per c.mm.

I am indebted to Dr. Bramwell for permission to publish the notes of this case.

G. W., aged 30, single, a wine merchant's traveller, was admitted to the Edinburgh Royal Infirmary, under the care of Dr. Byrom Bramwell, on March 5th, 1909, complaining of nervousness and difficulty in speaking.

History.

The history furnished by an intelligent sister was that in July, 1907, it was noticed that he was beginning to speak indistinctly, slurring his words now and then. About six months later occasional twitchings of the lips and unsteadiness of the tongue were noticed. In the summer of 1908 he had a great deal of worry connected with money matters; shortly afterwards the articulation and the movements of the lips seemed to get worse. He was able to work up to June, 1908, but then found he was unable to get on with his employers; he had lived at home since.

His sister had noticed very little change in his general behaviour. There had been no grandiose ideas; his power of concentration was, she said, unaffected.

In 1898 the patient contracted syphilis, developed a rash and sore throat, and took pills for over six months. He had had no other illnesses of note.

Family History.

Nothing bearing on the case.

Social Conditions.

The nature of the patient's employment afforded numerous opportunities of taking wine and spirits, of which he seems to have availed himself freely; he states that at times he drank to considerable excess.

Present Condition.

The patient is a very strong, heavily-built man, with a somewhat hang-dog expression. His weight is 15 st. 5 lb.; two years ago he weighed over 15 st. There are no signs of syphilitic disease on the surface of the body.

Nervous System.

Although his mental symptoms are not well marked, yet there is something strange in his manner. While speaking to

Fig. 1.—Photomicrograph of a lumbar puncture film in the case of general paralysis described in the text, magnified 50 diameters. The film was made after centrifuging 5 c.cm. of the fluid for ten minutes. The photograph was taken from a thin portion of the film.

the diagnosis of the parasyphilitic diseases of the nervous system.

Under normal circumstances the number of lymphocytes in a field of 450 diameters, in a film made after centrifuging 5 c.cm. of the cerebro-spinal fluid for a period of ten minutes, is usually two or three. In tabes and general paralysis of the insane the number is greatly increased. In several of Dr. Bramwell's cases which I have examined during the past six months the number has been from 200 to 250. Dr. Purves Stuart states that he has observed 450 in a field. In the following case the enormous number of 3,450 was counted in a single field of 450 diameters; in places where the film was thick this number was greatly exceeded, but, owing to the thickness of the clumps, the

Fig. 2.—Photomicrograph of a lumbar puncture film in the case of general paralysis described in the text, magnified 50 diameters. The film was made after centrifuging 5 c.cm. of the fluid for one minute. The photograph was taken from a thin portion of the film.

him you get the impression that you are dealing with a person of rather childish intellect. Sometimes he is timid, at other times suspicious and morose.

There are no abnormal sensations (paraesthesiae) and no objective disturbances of sensation, except that the patient is rather less sensitive to pain than the average man.

The gait is normal; there is no Rombergism and no paralysis. In the muscles of the legs, and to a lesser extent in those of the arms and trunk, there is a curious fibrillary tremor. When the patient holds out the hand there is a slight tremor. There is marked tremor of the lips, tongue, facial muscles, and eyelids.

The tremor of the eyelids is very marked when the eyes are tightly shut. There is no ocular paralysis and no definite nystagmus, though the eyes are jerky when the patient tries to fix a near object. The pupils are equal, each measuring 4 mm. in diameter; the left pupil is very slightly irregular in out-

line; both pupils contract to light and on convergence. The optic discs are normal.

The articulation is much affected, slurring and indistinct, and is accompanied by inco-ordinate movements and tremors of the lips and tongue. "Hippopotamus" and other test sentences are pronounced in the characteristic C.P.I. fashion.

All the deep reflexes are distinctly exaggerated. The plantar reflex shows active flexion; the abdominal and cremasteric reflexes are present. The organic reflexes (bladder and rectum) are normal. There are no signs of disease in the other systems or organs.

Lumbar Puncture.

An examination of the cerebro-spinal fluid revealed some very interesting facts. The fluid came out under distinct pressure; it was very slightly turbid; this turbidity was not due to the admixture of blood; it was alkaline in reaction, and had a specific gravity of 1.001.

After centrifuging 5 c.cm. of the fluid for ten minutes, decanting and examining the deposit, it was found that the film presented an extraordinary appearance. Here and there the leucocytes were collected in great masses several layers thick; between these masses they were more sparsely distributed (Fig. 1). In places where the distribution was fairly uniform there were, under a magnification of 450 diameters, about 3,400 leucocytes to the field (Fig. 2).

In a fresh specimen of the fluid which had not been centrifuged, there were on an average 285 leucocytes per c.mm.

In the dense parts of the film all the leucocytes appeared to be lymphocytes, but in the thin parts it was found that polymorphs were present in the proportion of 1 to 5. The lymphocytes varied considerably in size, the great majority being small.

Chemical examination showed that the fluid contained a large amount of albumen.

A lumbar puncture was made on several different occasions and the results verified by Dr. Edwin Bramwell, Dr. Ford Robertson, and Dr. W. T. Ritchie. Dr. Ford Robertson and Dr. Ritchie made bacteriological examinations of the fluid, with negative results.

ANAESTHETICS IN GENERAL PRACTICE.

By H. BELLAMY GARDNER, M.R.C.S., L.R.C.P. LOND.,
FORMERLY INSTRUCTOR IN ANAESTHETICS AT CHARING CROSS
HOSPITAL, ETC.

It is my intention in this paper to recount some of the details which procure success in the administration of anaesthetics in general practice. It would not be wise to refrain from the preliminary remark that safe anaesthesia cannot be conducted without actual personal practice on the part of the administrator, for the larger his experience of its difficulties the greater becomes his facility in preventing their onset, and in correcting untoward symptoms when they have arisen.

There are two main principles by which the administrator must be guided in his care of an unconscious patient: (1) To retain a weakly active corneal reflex, and (2) to keep the airways clear.

1. The Corneal Reflex.

The most sensitive spot on the eye is the centre of the cornea opposite the pupil. This is protected from injury in daily life by the smart closure of the upper eyelid on contact with a foreign body. When a patient is unconscious the muscular reflexes are gradually lost in a definite order as narcosis deepens, but the sensitiveness of the centre of the cornea does not disappear until last of all, and this happens before the respiratory and cardiac centres are themselves invaded.

I cannot lay it down too emphatically as an invariable law that it is impossible under any known conditions for the respiratory centre or the cardiac centre to be poisoned by chloroform or ether whilst the upper eyelid still closes when the centre of the cornea is touched by the finger.

This sign, therefore, furnishes an absolute guide to safety, in that, if by careful frequent testing of both corneae a condition of weakly active reflex closure of the upper eyelid is always retained, any complications which occur cannot be due to central poisoning of the respiratory or cardiac nervous mechanisms. An extraordinary fact connected with this simple procedure is that so very few know how to do it. The administrator stands behind the patient, and uses only one finger with which to raise the upper eyelid and touch the cornea. That is, he should insert the pulp of his middle finger between the palpebral edges, drawing the upper eyelid upwards and at the same time brushing that finger pulp lightly against the centre of the cornea. When he has arrived at the upper limit of

the pupil he should let go altogether, noting both by the senses of touch and sight the degree of briskness with which that upper eyelid closes.

The frequent mistake which is made verges on the ludicrous, for the eyelid is held open with one finger so that it cannot move at all, and then the cornea is rubbed with another finger whilst the observer gazes doubtfully at the inert ocular globe.

An improperly elicited corneal reflex is not only useless but dangerously misleading. The sclerotic portion of the eyeball is weak in tactile sensibility, and is useless as a guide in surgical anaesthesia. The lower eyelid in man does not and is not intended by Nature to cover the cornea, and corneal contact has practically no effect upon it in the unconscious state. There is only one proviso with regard to this sign, which is that when a definite difference exists in the activity of the two upper eyelids, we must be guided by the more active. Working on this principle, on account of the fact that a large pupil is found both in the second and fourth stages of anaesthesia, which can only be differentiated by reference to the activity of the corneal reflex, pupillary signs may be neglected altogether. A progressive dose of chloroform or ether having been given until the upper eyelid is weakly active in response to corneal contact, this condition can be exactly retained throughout by stopping the anaesthetic for a few breaths to quicken its activity, or giving more anaesthetic to weaken it as required.

Put in another way, the addition of more anaesthetic by the administrator should always be a guarantee to the surgeon and onlookers that the patient has at that moment a demonstrable corneal reflex.

2. To Keep the Airways Clear.

It is necessary to know by the sound of the breathing, when they are clear. There is, of course, a distinct difference between the sounds of inspiration and expiration; but this is only known instinctively after careful practice. The rule in anaesthesia is that every expiration must be either heard or felt by the administrator in order to make sure that efficient breathing is going on. It is of no use to see the abdominal and thoracic movements, for they may proceed for a considerable time after obstruction to air entry has taken place. Fifteen years' experience has taught me that unrecognized obstruction to air entry is the main factor of danger and death in anaesthesia, that dosage regulated by the corneal reflex is rapidly learnt and easily adjusted; but that elimination of asphyxial factors in all cases is the avocation of an artist and the study of a lifetime. The successful elimination of the numerous possible asphyxial factors as they arise depends upon their immediate detection, causal differentiation and application of the proper remedial measure without hesitation. So subtle in their action are some of these factors that the clinical effect first noticed is often only a secondary syncopeal result upon the heart and circulation, when the general condition is graver than it ought to have been allowed to become.

Dusky of the lips and ears is a sign that air is not entering the lungs in adequate amount, and is due to this absence of air-intake, not to ether or chloroform *per se*. Here we have a definite physical sign, and the man who guides himself by the sound of breathing, putting in a small mouth prop, raising the jaw or drawing the tongue forward directly the sound of breathing through clear airways is replaced by that of partially obstructed respiration, prevents the onset of dusky and its consequent additional dangers.

I venture to assume that the operations for which anaesthesia is most frequently required in general practice, with the exception of dental extractions, are those undertaken by general practitioners themselves, and do not include those for which a surgeon has been engaged.

Dental Extractions.

In the employment of nitrous oxide gas for dental extractions, practice is especially required, not because of danger of giving an overdose, but on account of the extremely short anaesthesia which results from its administration.

Attention to a number of small details which greatly assist the dentist in his work is the only means of ensuring a painless operation under its influence. We

should remember that patients usually obtain their first practical knowledge of surgical anaesthesia in the dental chair, and in order to obtain the confidence of the public we should be most particular that no pain whatever is felt during dental extractions, so that when serious surgical operations have to be faced fear of a semiconscious condition may not be added to the patient's other trials.

There is a very great difference in the amount of nitrous oxide required by lethargic persons of slow speech and nervous, rapid talkers; the well-nourished, healthy girl of 15 provides the ideal subject; the powerfully-built plethoric man the most difficult.

In the first place, in order to prevent the tongue gravitating backwards and obstructing the airway, the patient *must* be seated quite upright in the chair with the head in a line with the body, *not* extended backwards. Dentists soon learn the value of this precaution, but if one should still insist that he cannot operate on a particular tooth in this position (though I think it is quite a fallacy), the chair may be inclined a little backwards after anaesthesia has been induced just before the removal of the facepiece. Dr. Hewitt's mouth props for insertion between the molar teeth are the best, because they bridge across two or three teeth and do not become dislodged. They should be placed in the mouth upon the side opposite to the site of the first extraction and kept in place by slight pressure upwards against the lower jaw.

The dental chair should not be raised very high, for unless both are tall men the doctor's control of the patient and the poise of the dentist are both lost by the patient being out of proper reach.

Movements of the patient's legs nearly always take place during gas anaesthesia, and his heels should therefore be either resting loosely on the floor of the room on either side of the chair or over the end of the chair platform, so that the legs are relaxed and no fulcrum exists for the limbs to push the body backwards and disturb the position of the head. Many an otherwise successful case has been ruined for lack of this simple precaution, which should never be neglected. The fingers of the patient's hands should be interlaced and clasped together in the lap for similar reasons.

Men's collars should be removed to prevent their being soiled by blood, which always runs out of the mouth straight down the chin and neck. Patient's friends should not be allowed near the chair, but placed some way off behind it where they cannot see the patient's face and the actual operation, but most patients behave better without friends in the room.

Too much should not be promised nor attempted at one sitting. I have a very great respect for the difficulties of tooth extraction, and one tooth may often require two doses of ordinary gas for its extraction if it should break off before its roots are all out. Two, or at most three, average teeth should only be promised at one sitting, unless they are loose.

Supposing the teeth to be extracted to be on both sides of the mouth, the doctor can give the best help in keeping the mouth open if the extractions are first made on the patient's left side—that is, the side upon which the doctor stands, for when these are finished he can then most readily slip in a Mason's gag on this left side, and pull out the mouth prop from the right side ready for the next extraction. The doctor should always have a clean sponge at hand to aid the dentist in sponging blood away from the alveolar margins during root extractions.

Oxygen in varying quantities from 6 to 15 per cent., added to nitrous oxide according to requirement, in order to eliminate asphyxial factors, aids enormously in the management of all kinds of patients, and personally I never administer it without. Great advantage can be obtained by the use of nitrous oxide and oxygen through Paterson's nosepiece for continuous administration, which I employ for difficult cases requiring four or five minutes' anaesthesia. The nearest approximation to the good colour and tranquillity ensured by the addition of oxygen is attained with the simple gas apparatus by admitting one breath of air after ten respirations of gas, and another breath of air at each succeeding fifth respiration until the eyes are in a fixed position, and some stertor has arisen. Absolute silence should be maintained during the operation as talking is remembered by the patient afterwards. Towards the termination of the period of anaesthesia the

dentist should be told to "stop" at the moment when, the left eyelid being held open, voluntary movements of the eye in looking round recommence. Sensation to pain is the last faculty to recover from nitrous oxide anaesthesia.

Gas and ether is most valuable in more extensive dental operations, and may quite safely be given to patients sitting upright in the dental chair, though it is best to lay them flat on a sofa for the after-period of recovery. With a Clover's gas and ether apparatus, a small mouth prop always being first inserted, five breaths of nitrous oxide are first given, the valves are then thrown out of action, and rebreathing into the gas bag commenced; immediately after this, ether is gradually introduced; when stertor has arisen, the small ether bag is applied instead of the gas bag, and a breath of air allowed at every fifth respiration. One good dose of ether taking five or six minutes to administer produces more satisfactory anaesthesia and less after-effect than two or three short doses, and when ether has been chosen this plan should always be followed. Children awake very quickly from a single dose of ether.

Circumcision.

More deaths and conditions of danger under chloroform have occurred during circumcision than are warranted by the gravity of the operation. In infancy and early childhood the C_2E_2 mixture followed by ether on an open mask should be used, because the reflex effect upon the respiration always produced by nipping and cutting the prepuce is not so marked nor so dangerous when respiration is fairly deep, and the circulation well stimulated by ether.

It is not wise nor necessary to obtain a degree of anaesthesia free from all reflex movement of the thighs for circumcision in childhood; but, having weakened the corneal reflex, it is well to get the nurse to place her hand on the patient's knees to prevent their upward reflex movement when the prepuce is first seized and to keep them down during the operation. Reflex laryngeal crowing almost always arises also at this moment, and the lips should then be rubbed briskly with a towel to stimulate deeper breathing; the jaw should be pushed forward and the anaesthetic withheld until respiration is more regular.

For adults gas and ether or open ether is the proper anaesthetic.

Ingrowing Toenail.

If nitrous oxide and air be the anaesthetic selected, an assistant should be present to hold the leg above the ankle, or it must be tied down securely to the bed, because the extremities are extremely sensitive, and reflex movements of the feet and legs are certain to take place and cannot be controlled by this anaesthetic.

I am, however, of opinion that in order to complete the operation when undertaken at the patient's house, it is far more satisfactory to put the patient under the influence of the C_2E_2 mixture or open ether, when all need for undue haste is avoided, muscular flaccidity is obtained, and if the patient is prepared by four or five hours' abstinence from food, after-effects are very slight indeed.

Adenoids and Enlarged Tonsils.

It must be borne in mind that patients with these affections have more or less obstructed air passages, and that the operation and the bleeding it causes also cause intermittent respiratory obstruction.

Chloroform *plus* asphyxial factors of this severity is unnecessarily dangerous. The C_2E_2 mixture is, without doubt, the most appropriate anaesthetic, because it keeps the patient's colour pink, and maintains moderately deep breathing, a condition which allows of short intermittent spells of air limitation without much fear of depression. Dosage should proceed until the corneal reflex is definitely weak, then three or four respirations of air should be allowed before beginning the operation, so that it may be done during the *return* from the maximum dose, thereby retaining the coughing reflex to reject the blood from the throat.

It is wrong to anaesthetize small children in one room and then carry them into another room for operation. The movement lowers the blood pressure dangerously, and greatly increases the risks of the whole proceedings. Children are not dismayed by lying down upon a proper table in a warm room prepared for operation, but are only mildly interested in the novelty of its appearance. The

induction of anaesthesia in a child's iron cot with high barred sides is very difficult, and the child is most apt afterwards to associate its experiences with its own sleeping bed instead of with a table which has then been taken quite away.

The mothers of these children are frequently absurdly lacrymose, and unnerve the child by their presence at the beginning of affairs. The surgical nurse or doctor should therefore take them into the room and the mother should go downstairs until called for after all has been completed.

Sebaceous Cysts.

These cannot be completely removed under nitrous oxide gas owing to venous oozing obscuring the cyst wall, and the C_2E_2 mixture is the most satisfactory anaesthetic for the patient and operator. These cysts are not very sensitive unless inflamed, and there is no need for a very deep anaesthesia. Their position on the scalp is often somewhat inaccessible when the patient is lying down, and a table should be used instead of a bed, so that the head may be properly reached from its upper end. If the patient has to be laid partly on his face he should be anaesthetized lying on his side and then rolled into position, care being taken that the chest walls can freely expand in respiration.

Dislocations.

Patients meeting with an accident causing dislocation of a limb are unprepared by abstinence from food for an anaesthetic, and are not likely to take it well. A jaw gag must be at hand in case of semi-solid vomiting, and, whatever anaesthetic is used to make the patient unconscious, ether should afterwards be given to obtain muscular relaxation. A great many deaths have occurred under chloroform unwisely pushed for this purpose. C_2E_2 followed by ether or gas and ether are the most suitable and safe anaesthetics to employ.

Diagnostic Examinations.

Chloroform may be wisely administered for examinations, except in rectal cases, where dilatation of the sphincter and causes reflex laryngeal spasm and ether should be used.

As chloroform requires some days for its complete elimination from the blood, it is wise not to employ it for a lengthened examination the day before a contemplated operation. After an interval of four days less after-effects result from the second anaesthetic.

Just as much careful watching of the patient must be practised as during a surgical operation; but two great factors, namely, the inhibitory reflex effects produced by surgical stimuli and haemorrhage, are absent.

Parturition.

One observation only is needed in conclusion. It should not be forgotten that all the conditions during confinements are extremely favourable for the administration of chloroform—the lateral posture, the higher blood pressure, the deeper respiration, all assist materially in the maintenance of circulatory equilibrium. The absence of difficulties and depressing effects from chloroform at confinements must not be looked for in other patients during other operations.

RESECTION OF THE TRACHEA FOR CICATRICIAL STENOSIS.*

By G. GREY TURNER, F.R.C.S.,

TANT 3 GEOR. ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

So far as I can gather, it seems usual in cases such as that about to be described to attempt to dilate either through the larynx or a tracheotomy opening, but these methods are exceedingly tedious and admittedly unsatisfactory. In a *System of Practical Surgery*, by Professor E. von Bergmann, vol. xi, p. 220, it is stated that "extensive circular scar stenoses or complete occlusion form an indication, according to the experience of Kuster

and v. Eiselsberg, for circular resection with subsequent suture of the trachea." In my case the trachea rapidly became obliterated by a considerable mass of new tissue, and it seemed to me in accordance with surgical principles to excise the involved segment when dealing with a non-collapsible tube of large calibre like the trachea. The occurrence of so serious a complication as secondary haemorrhage may appear as a fitting rebuke for adopting an audacious proceeding, but it appeals to me rather as a warning against the close suture of the external wound in cases where the area has become septic from the constant presence of a tracheotomy opening.

The patient was a man of 25, who inflicted the injury in a fit of depression following alcoholic excesses.

He was admitted to the infirmary on April 16th, 1908, in such a collapsed condition that his recovery was despaired of. There was a fearful gash in the neck almost completely severing the trachea, though the great vessels had escaped.

Next morning he was so much better that chloroform was administered and the injured parts thoroughly examined by the house-surgeon. It was then found that the trachea had been divided just below the cricoid cartilage, and that the sterno-mastoid and infra-hyoid muscles had been partially divided. The wound was thoroughly cleansed and the trachea drawn up to the cricoid with three catgut sutures, the muscles being separately repaired with catgut. Tracheotomy was not considered necessary, but the superficial wound was left partly open.

From the time the patient first began to talk the voice was characteristic of recurrent laryngeal paralysis, and this condition never altered. Unfortunately suppuration occurred, and the wound only healed slowly by granulation. The sutures holding up the trachea gave way, and it was found necessary to introduce a tracheotomy tube. As cicatrization proceeded all attempts to displace with the tube gave rise to much distress, and it was obvious that the trachea was becoming stenosed.

On May 15th an anaesthetic was again administered, and just above the tracheotomy opening the trachea was found so much stenosed that it would only admit a fine probe through a channel at the summit of a funnel-shaped narrowing. It was found possible with a pair of sinus forceps, followed by artery forceps, to easily dilate the stricture, and an attempt was made to keep it patent by a silver tracheotomy tube passed upwards into the larynx through the top of a large rubber tracheotomy tube introduced in the usual way in imitation of Störk's tracheal cannula and dilator. As might have been expected, this plan was not successful, and, in spite of all our efforts to keep the trachea open, it became necessary to interfere again, or let the case drift into one of permanent stenosis with its necessary tracheotomy.

On June 12th the last operation was performed, again under general anaesthesia. This time complete obliteration was found, the lumen of the trachea being filled by a mass of scar tissue: it was therefore decided to resect the involved portion. The cricoid and the upper part of the windpipe were accordingly thoroughly exposed through a vertical incision, and a complete segment of the trachea excised. The resulting gap was very wide, but the trachea was found without fear until it could be easily approximated to the cricoid, to which it was fixed by several No. 1 chromic catgut stitches passed around the upper ring of the trachea and through the cricoid, care being taken to tie the knots on the outside. The posterior and lateral surfaces were brought into perfect apposition, but there was a little irregularity of the union in front. A vertical opening was made into the trachea about 1 in. below the line of suture for the introduction of a small silver tracheotomy tube. The skin incision was then carefully closed by silk-worm stitches. The part removed consisted of a complete transverse section of the trachea with two rings, the lumen being completely obliterated by a mass of scar tissue.

For five days the patient went on very well, but there was then a little suppuration with rise of temperature, and the skin wound gave way. On the eighth day, without any warning, he had a sudden profuse haemorrhage. The bleeding was clearly from the left side of the wound from a recess by the side of the trachea, and, after resisting all the efforts of the house-surgeon, it stopped spontaneously. As the source of the haemorrhage was doubtful, and its spontaneous arrest probably only temporary, I thought it wiser to give an anaesthetic, and, if possible, deal directly with the bleeding point. As a matter of fact, I was only able to curette a small area, which I packed from the left side in dressing in turpentine. As one or two of the sutures in the front part of the tracheal wound had given way, two silk-worm stitches were introduced and subsequently removed.

After this the patient made a straightforward recovery and was soon able to leave the hospital, the wound healing completely in the sixth week following the resection operation. When shown at the meeting in December, 1908, he was well and happy in daily breathing except on severe exertion or when suffering from cold. The scars in the neck were not very obvious, but on palpation the trachea was found to be a little narrowed from before backwards and this was well shown on x-ray examination.

Dr. S. S. Whillis kindly examined the larynx and reported paralysis of the left vocal cord, general hyperaemia of the laryngeal and tracheal mucous membranes, but no evidence of stenosis as far as could be seen.

*The case that forms the subject of this note was shown at a meeting of the Newcastle-upon-Tyne Clinical Society.

TREATMENT OF FACIAL PARALYSIS DUE TO DIVISION OF THE FACIAL NERVE IN THE MASTOID OPERATION.

By F. MARSH, F.R.C.S.,

CONSULTING SURGEON, QUEEN'S HOSPITAL, BIRMINGHAM.

IN the JOURNAL of May 8th a case of anastomosis of the facial nerve in the aqueduct of Fallopius is described by Dr. F. Sydenham of Walsall. It may interest him and other surgeons to know that a procedure similar in detail has been employed by me in two cases.

CASE I.

Mr. P. H. was operated on in 1900. The facial nerve had been divided by a splinter of bone when "the bridge" was being cut away with a chisel. The division was not noticed at the time, but the paralysis was complete on recovery from anaesthesia. As this persisted, the wound was reopened a fortnight later. The facial nerve was seen to be completely divided, and the proximal end frayed and everted by the gauze packing. At the suggestion of my colleague, Mr. Jordan Lloyd, who was present at both operations, the proximal end was teased into its normal position—coming almost in contact with the distal end; two or three strands of fine chromic gut were placed round the nerve, the ends being inserted into the bony canal, and the parts protected for a short time by gutta-percha tissue in the way described by Dr. Sydenham. Gentle galvanism was subsequently employed; slight return of power commenced in six weeks, and complete recovery resulted.

The case, though not published, has been related to several of my colleagues in the Midlands.

CASE II.

Miss H. F., aged 26. The facial nerve was divided on January 14th, 1908, in clearing a cholesteatomatous mastoid which had been operated upon twice previously, the relation of the parts being much altered by bone absorption. The division was recognized at the time, and the nerve ends were carefully approximated and protected for a few days with gutta-percha tissue. The operation cavity became rapidly covered with epidermis from the mental flaps, under hydrogen peroxide and spirit treatment. As no sign of regeneration appeared in a month (February 15th) it was decided to reopen the cavity and examine the nerve ends. It was not easy to define these again in the cicatrized tissue and to be certain that no union had taken place, indeed it seemed both to me and to Mr. Seymour Jones who assisted me that there was continuity of a few of the deeper fibres. The ends were readjusted, and a strand of fine chromic gut was with difficulty inserted in each of the aqueduct openings. The post-aural wound was closed, and the cavity rapidly healed without suppuration. Gentle galvanism was continued, but it was not until the end of June—four months later—that signs of power commenced in the mouth muscles; the improvement steadily extended to the other muscles, and the power has now (May 7th) returned to all except the corrugators of the brow.

In this case it is difficult to estimate the value of the second operation; it seems not improbable that if more patience had been exercised the first adjustment would have been all that was necessary.

It, however, showed that the operation is more difficult when the post-aural cavity is completely cicatrized than when it is in a recent post-operative condition.

The cases themselves show:

1. That if division of the facial nerve is recognized at the time of operation, careful adjustment in the manner indicated will probably result in restoration of function.
2. That if division has not been recognized, the wound should be reopened and the nerve ends adjusted at the earliest possible opportunity.
3. That if a careful adjustment has been made a second operation should not be undertaken within three or four months.
4. That this method of adjustment should be tried before anastomosis with the hypoglossal or spinal accessory nerves is attempted, the results of which are not always gratifying.

UNDER the will of the late Mr. Frederick Gorrings, the draper and silk mercer of Buckingham Palace Road, the Clapham and General Provident Dispensary receives a bequest of £1,000. On the death of the testator's wife £5,000 is to be paid to the Bolingbroke Hospital, and the residue of the estate after payment of other bequests divided in equal shares between some eight institutions. Among these are St. George's Hospital and Westminster Hospital; each, it is calculated, will ultimately benefit in this way to the extent of some £50,000.

MEDICAL, SURGICAL, OBSTETRICAL.

DISTRIBUTION OF BILHARZIOSIS ON THE VICTORIA NYANZA.

DURING a visit in January, 1909, to Usukuma on the Southern Shore of the Lake Victoria Nyanza, German East Africa, I was astonished to find at Nassa (a little place some 60 miles east of Mwanza, and on the southern shore of Speke Gulf) a very high proportion of the natives suffering from the symptoms of bilharziosis. I was only able to stay two days in that place, but of 156 patients whom I examined exactly half had the symptoms of bilharziosis of the bladder. Three of these chosen at random were asked to pass urine, and a drop of the urine (not centrifuged) showed in each case enormous numbers of typical ova. One of them was the local king or chief. The briefness of my visit prevented me from investigating the percentage of the general population so affected, nor was I able to investigate the presence or not of ova in the stools. The interest of the observation lies partly in the following facts:

1. The natives obtain their drinking water from the lake, and this lake is the source of the Nile, on the banks of which bilharziosis is endemic. The water is stored, as in my own neighbourhood, in earthenware jars of large size, which are seldom if ever cleaned. The natives likewise (or certain classes of them) do a good deal of wading in the water to fish, though this would not be true of the chief and upper classes.

2. On the northern shore of the lake bilharziosis is comparatively rare. I am told that in Entebbe bilharzia is occasionally found, especially in the stools. But in our hospital at Mengo (with an in-patient attendance of about 1,600 patients per annum, and an out-patient attendance of about 13,000 new cases every year) we have during the past thirteen years seen only two cases of bilharziosis, and they were probably not endemic. Mengo is only eight miles from the lake shore.

Mengo, April 6th.

FATAL HAEMOPTYSIS IN AN INFANT.

THE patient in the following case, an infant aged 3 months, was the child of a puny, young, phthisical mother. It was stated to have kept in good health for four weeks after birth, and then commenced to have fever and cough. For nearly two months the fever never left the child, its cough was very frequent. When I saw it for the first time, a couple of days before its death, the cough was almost incessant. One evening the child was brought to my surgery in great haste, as it was supposed to have vomited blood. It was pulseless, and blood was oozing from its mouth and nose. The coat of the father, who had brought it in his lap, was saturated in front with blood. On inquiry I found that just half an hour before the child was brought to me it had a violent fit of coughing, and blood began to run from its mouth and nose. The haemorrhage proved fatal. That this infant had caught tuberculous infection from its mother and that the violent cough ruptured the pulmonary blood vessels and brought on the fatal issue is clear; but the extreme youth of the patient, which had barely completed the third month of its life, makes the case worth reporting.

A week after the baby's death the mother died also.

E. H. THOMAS, M.B., L.R.C.P. and S. Edin.
Dehra Dun, India.

FACIAL PARALYSIS FOLLOWING EMOTIONAL SHOCK.

Mrs. B., aged 38 years, consulted me for complete facial paralysis of the left side. She gave the following history: On Monday morning she was in perfect health. At breakfast she opened the paper and was startled to find news of a terrible shipping disaster, the *Penguin*, a local steamer, had sunk causing a great loss of life. She says that while reading the account of the wreck, she felt a sensation of "clawing" in her left cheek. Two hours later the left side of the face was completely paralysed.

I saw her twenty-four hours later. On examination the whole side of the face was motionless, all the branches of

the nerve were involved, the sense of taste and of hearing being normal. There was no reaction to either galvanic or faradic currents. No reaction of degeneration was present.

The treatment was high frequency currents, continuous current (anode placed behind the ear), and massage, potassium iodide being given internally.

Fifteen days later the patient wrinkled the forehead slightly, a few days after this the mouth could be lifted a little, and at the end of thirty days all the normal actions of the face could be performed.

I have never seen a case of facial paralysis from emotion, and I most carefully questioned the patient as to the possibility of having been in a draught or having had a blow, etc.

P. CLENNELL FENWICK, M.D.,
Surgeon to Christchurch Hospital, New Zealand.

Antityphoid Inoculation.

MAJOR H. W. GRATTAN and Captain A. L. A. WEBB demonstrated the method of preparing antityphoid vaccine at the Royal Army Medical College. During the last twelve months they had prepared and issued 40,800 double doses for the use of the army both at home and abroad. The vaccine, they said, was prepared from a broth culture of the typhoid bacillus, some of the points on which they laid special stress being that the culture should not be overheated (a temperature over 53° C. had been found to have a deleterious effect on the immunizing properties of the vaccine), that the antiseptic (0.25 per cent. lysol) should not be added until the vaccine had cooled down, and that the vaccine should not be used later than three months from the date of manufacture. These conclusions had been reached by experimental work on the protective substances found in the blood of men and animals inoculated with vaccines prepared at different temperatures, and of different ages. They quoted the most recent statistics available, which had been compiled by Brevet-Lieutenant-Colonel W. B. LEISHMAN, R.A.M.C., and published in the February number of the *Royal Army Medical Corps Journal*.

The total strength of the 16 units under observation was 12,083, and amongst the inoculated—5,473 in number—21 cases of enteric occurred with 2 deaths. The remaining 6,610 non-inoculated men served as a control, and amongst them occurred 187 cases of enteric with 26 deaths.

THE ROYAL SOCIETY.

Thursday, May 20th, 1909.

Sir ARCHIBALD GEIKIE, K.C.B., President, in the Chair.

The Urine in Diseases of the Pancreas.

DR. P. J. CAMMIDGE reported that in the course of a series of observations on the metabolic changes associated with diseases of the pancreas he had found that if the urine of a patient suffering from an inflammatory affection of the gland were boiled with hydrochloric acid, the excess neutralized with lead carbonate, and the freed glycuronic acid precipitated out with tribasic lead acetate, treatment of the filtrate with phenylhydrazin, after the excess of lead had been removed with sulphuretted hydrogen, yielded a crystalline product which varied in amount with the intensity and stage of the disease. Normal urines and specimens from patients suffering from diseases in which there was no reason to think that the pancreas was involved gave no reaction. Twenty-eight cases in which the urine had been examined during life were investigated *post mortem*, and the results of the urinary examination confirmed. The urine of three dogs with experimentally induced acute or chronic pancreatitis was found to give a characteristic reaction. A detailed examination of a large quantity of urine from each of eight patients giving a well-marked reaction showed that it was due to a sugar having the reactions of a pentose, and

yielding an osazone with a melting point of 178° to 180° C. Attempts to isolate the mother substance were not successful; it would appear to be derived from the pancreas, and was probably set free as the result of degenerative changes in the gland, passing into the blood, and being excreted in the urine.

Incidence of Cancer in Mice.

DRS. E. F. BASHFORD and J. A. MURRAY (Imperial Cancer Research Fund) stated that the relative frequency of cancer at different age-periods in female mice had been determined on animals bred for the purpose, the ages, sex, and parentage being carefully recorded. The diagnoses had been made by combining clinical observation with microscopical examination and transplantation of the tumours, and with *post-mortem* examination of the animals. Following Jensen, they had demonstrated in 1903-4 that cancer could be transmitted artificially from one individual to another of the same species by the implantation and continued growth of living cancer cells, and had shown that this form of transmission was not responsible for the great frequency of the disease. Other authors had since described "epidemics" of cancer in animals, especially mice. In the course of a year 19 cases of cancer had been seen in the mice under observation. This aggregation of cases corresponded to the "epidemics" adduced as evidence that the disease was infective. The cases had been analysed with reference to the age at which the tumours were first observed. The liability to cancer at different age-periods was as follows:

	6-7 months.	-12 months.	-15 months.	-18 months.	-21 months.	-24 months and over.
Total ..	135	112	94	21	6	...
Cancer ...	3	4	7	3	2	...
Per cent. . .	2.2	3.5	7.4	14.2	33.3	...

The progressive increase shown in the table presented a remarkable parallel with the age-incidence of cancer in the human subject, and confirmed the earlier statements of the authors (*Proc. Roy. Soc.*, January, 1904, etc.) that in animals, whatever their length of life, the recorded frequency of cancer varied, as in man, with the opportunity for examining a sufficiently large number of adult and aged individuals. The observations also added a statistical confirmation to the results of the comparative histological and biological studies of the Imperial Cancer Research Fund, which had shown the close parallel, amounting in many particulars to complete identity, between malignant new growths in man and other vertebrates. They demonstrated that the law of the age-incidence of the disease held for the shortest-lived mammals as for man. Since the facts agreed with the less perfect data for other vertebrates, the general application of the law of age-incidence was probable, and therefore any explanation of the etiology of cancer must accord with the circumstance that when considered statistically cancer was a function of age, and when considered biologically a function of senescence.

Volume of the Blood.

DRS. J. O. WAKELIN BARRATT and WARRINGTON YORKE (Liverpool) described a method of estimating the total volume of blood contained in the living body. The principle employed was that of injecting into the blood stream a known amount of dissolved haemoglobin, and then determining the degree of the resulting haemoglobinaemia. This enabled the volume of the blood plasma to be calculated, and, with the aid of a haemocrit determination of the composition, by volume, of the blood, the total amount of blood present in the living body was ascertained. The haemoglobin employed was obtained from the red blood cells of the subject of observation. No ill effect had been observed after injection of dissolved haemoglobin. The estimation of haemoglobin was generally made with von Fleischl's haemoglobinometer, the scale of the instrument having been previously standardized by means of solutions containing known amounts of red blood cells. When the depth of the natural colour of the blood plasma before injection was markedly increased, as sometimes happened,

it was difficult to obtain haemoglobinometer readings of the amount of dissolved haemoglobin present after injection. In such cases the blood plasma, suitably diluted, was matched, by means of a comparison spectroscope, with solutions containing known amounts of dissolved haemoglobin.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Friday, May 7th, 1909.

JOHN LENTAIGNE, P.R.C.S.I., President, in the Chair.

Bier's Hyperaemia Treatment.

MR. R. ATKINSON STONEY, in a paper on treatment by passive hyperaemia produced by means of elastic bandages and suction glasses in tuberculous disease, said that his experience had not been promising. He had, however, not dealt largely with cases of this order. Excessive hyperaemia should be avoided, and in applying glasses ordinary aseptic precautions should be observed. The glass should be of sufficient size to leave a margin of 1 in. or more around the inflamed part or opening, to prevent strangulation or compression of the lips of the opening. Pain should not be produced. And, especially where the cup was placed over a superficial bone or firm membrane, excessive pressure should not be used, for fear of sloughing of the parts. The PRESIDENT said he had been deterred from the use of the method by its unsatisfactory results in the hands of some surgeons, but Mr. Stoney had helped to explain some of those results. He had recently been converted to its use for boils, but he had seen a great number of cases of tuberculous disease which had deteriorated under the treatment, and in some cases he could not satisfy himself that the dissemination of the tuberculosis had not been in some way due to it. Mr. L. G. GUNN said he had tried the treatment in cases of knee and wrist trouble, but found it impossible to produce any degree of congestion without pain. He was therefore not surprised at getting no good results. He thought French and English people, and more particularly Irish people, probably felt pain more acutely than the Germans, which might explain the differences in results. Mr. W. I. DE C. WHEELER confessed the same experience as Mr. Gunn, but in cases such as gonorrhoeal rheumatism he did find some easing of pain, and apparently some improvement. Mr. PEARSON said that the use of the band would seem to lead naturally to the increase of pain, as it was chiefly a matter of tension, but the suction apparatus, by reducing atmospheric pressure, might produce an initial diminution of pain. Mr. STONEY, in reply, said the worst results had been got by Bier in the knee joint, for some reason which he could not explain. He did not suggest the treatment in any case where better results, or quicker equal results, could be obtained by operative means. It was in tuberculous cases that the greatest difficulty was found in producing the correct degree of hyperaemia. The question of tension was difficult to deal with. It was, however, easy to understand that pain, which might be due to irritation of the nerve terminals by toxins produced by organisms, might be relieved by the congestion causing a flow of blood and lymph and producing a dilution of the toxins.

Post-operative Tetanus.

Mr. GUNN having read a paper on post-operative tetanus, the PRESIDENT said he could imagine no more appalling catastrophe to happen a surgeon than to have a case, or series of cases, of post-operative tetanus. He could not help keeping to the belief that the catgut must have been responsible. It was curious that in every case in which the catastrophe had occurred catgut had been used. It would be important to know what methods of sterilization had been employed. He had himself been using the iodine catgut for some time, but if he was threatened by the terrible phantom of possible tetanus he would be inclined to give up catgut altogether. Dr. KATHERINE MAGUIRE said she had been in attendance on one of the cases mentioned by Mr. Gunn. It was not a case of hysterectomy alone, but was combined with ovarian tumour, and quantities of thick catgut had been used. She thought the case was probably hopeless from the first. She knew that the patient could not have contracted

the sheep disease mentioned by Dr. Richardson in his paper, as the patient had come from a part of England in which it was absolutely unknown. The time of the dissolving of the catgut was the time of being infected, and that had made it impossible for her to exonerate the catgut. Mr. PEARSON recounted the clinical history of one of the cases alluded to by Mr. Gunn, in which the patient died about twenty-eight or thirty hours after the onset. Mr. BLAXNEY said it seemed difficult to get over the fact that in every single case catgut had been used. They knew the source of the catgut and the possibility of its being infected, and these made the conclusion as to its responsibility all the more probable. The extreme virulence of the cases seemed to be at variance with the results of the bacteriological examination. The conditions inside the body were not such as would be expected to favour the growth of the bacillus; in two of the cases there was no suppuration, and therefore no septic organism to prepare the way for the bacillus, and the tissues were well supplied with oxygen, which was also unfavourable to the bacillus. Mr. GUNN, in reply, said Dr. Richardson had made extensive inquiries as to the methods of sterilization employed, and had then come to the conclusion that there was no absolutely perfect method.

Dr. NORMAN MOORE, Vice-President, in the chair.

Serum Treatment of Typhoid Fever.

PROFESSOR R. T. HEWLETT read a paper on the treatment of typhoid fever with an antientidotoxic serum. It was generally recognized that an antityphoid serum prepared by the injection of the horse with cultures of the typhoid bacillus was useless in the treatment of typhoid fever. An antientidotoxic serum had been made by the injection of the horse with typhoid cell juice. Such a serum had an active neutralizing power against both the typhoid endotoxin and the typhoid bacillus. The results of the use of this serum in 9 cases of typhoid fever were detailed. The impression which had been gained, so far, was that several cases were benefited, and that in 2 at least the disease was cut short by its use. The instillation of the endotoxin gave a reaction in some cases comparable with the Calmette reaction in tuberculosis.

Dr. E. W. GOODALL read a paper detailing the results of the treatment of 26 cases of typhoid fever with the same antientidotoxic serum in the Eastern Hospital, Homerton. In only 9 was there any reason to think that the injection of the serum had any beneficial effect. In the case that had the largest amount of serum injected no result was apparent. The conclusion was that it had appeared to do good in a few cases and deserved further trial. An ophthalmic reaction was obtained in a few cases of typhoid, but in 1 case of scarlet fever a marked reaction was given and none in other cases of scarlet fever. Thus a slight positive reaction could not be taken as diagnostic of typhoid fever.

Dr. BAUCE, of the Western Hospital, Fulham, also communicated notes of 5 cases of typhoid fever treated with the same antientidotoxic serum. His impression was that 2 at least of these were benefited by the injections.

Dr. HEWLETT, in reply to remarks, said that the effects of supersensitization were very manifest in some cases.

THE congress which met in Geneva last year to discuss the question of the suppression of frauds in food will be succeeded by a similar congress to be held in Paris during October of the present year. The congress is under the auspices of the Society of the White Cross of Geneva, which is presided over by M. C. H. Vuille. The General Secretary is M. Robert Fazy, 42, Rue du Rhône, Geneva. The principal object of the congress will be to define such methods as will prevent the fraudulent adulteration of food, but there will also be sections devoted to chemical products, pharmaceutical preparations, mineral waters, and similar substances. The congress will consist of two principal sections—technical and industrial. Any other information that may be desired can be obtained from Mr. Loudon M. Douglas, College of Agriculture, Edinburgh.

THE BIRTH OF MODERN SURGERY.

[WITH PORTRAIT OF LORD LISTER.]

It is a striking proof of the modesty of the begetter of modern surgery that he has never gathered together the scattered papers and addresses in which the results of the labours pursued *ohne Hast aber ohne Rast* through his long working life were conveyed to the scientific world. Too much cannot be said in praise of the beautiful simplicity of character which has made Lord Lister content to leave his work to speak for itself, and to keep silence in the face of misrepresentation and wrong-headed opposition. But we cannot help thinking that much of this would have been prevented had he set his teaching as a light fixed before the eyes of all men. To those who had not the good fortune to have his teaching stamped ineffaceably on their minds by the living word of the master and by the sight of his conquests over difficulties with which surgery had before been unable to cope, his own accounts of his work had become virtually inaccessible. No better way of honouring the occasion of his completion of his eightieth year could therefore have been found than the collection of his writings which has now been issued from the Clarendon Press.* The illustrious author is to be congratulated on the noble form in which the record of his labours—so fruitful of good to his fellow-men—is now permanently enshrined. A debt of gratitude is due by all interested in the history of modern surgery to the distinguished committee—consisting of Sir Hector C. Cameron, Sir W. Watson Cheyne, Mr. Rickman J. Godlee, Dr. C. J. Martin, and Dr. Dawson Williams—which undertook the task of preparing the work for the press. Of these gentlemen three were intimately associated with Lord Lister in his surgical work. Sir Hector Cameron was his dresser, then his house-surgeon, and afterwards his colleague at Glasgow; Sir Watson Cheyne was his house-surgeon, first at Edinburgh and then at King's College, London, where later he was his colleague; Mr. Godlee, who is closely related to him, worked with him at Edinburgh. The Committee had the advantage of Lord Lister's help, and has done its work with a reverent care worthy of the object on which it has been bestowed. The introduction which they have contributed is a masterly summary of Lister's work in which the sequence and relation of his varied researches are clearly pointed out. It is invaluable to the earnest student as a guide to the essential points of his teaching. Another useful help is a very copious index.

The writings are arranged under the four main heads of physiology, pathology and bacteriology, the antiseptic system, and general surgery. Some special addresses and lectures, which it would have been difficult to classify under any one of these headings, are placed in a fifth part at the end of the second volume. The papers in each part are arranged in chronological order, and the reader is thus enabled to follow the evolution of the doctrine which wrought a revolution more directly fruitful of good to mankind than any political upheaval or new invention of which there is record in human history. The plan of the work necessarily entails a good deal of repetition; but new ideas do not often find ready acceptance among the mass of men, and Lister had to preach his new surgical gospel to many deaf ears, and to not a few positive unbelievers,

before it was received as the guiding principle of surgical practice. As late as in 1883 we find him thanking an audience for their cheers, and saying that there was a time when such remarks might have met with a different reception. A few years before he had said that it seemed to be difficult for him to write the English language so as to make his meaning intelligible, so gross were the misconceptions of his ideas.

A complete analysis of the work before us would be impossible within the space at our disposal; this is not necessary, however, as a full account of the birth and growth of what may conveniently be called Listerism was given in a special number of the *BRITISH MEDICAL JOURNAL* of December 13th, 1902, on the occasion of the jubilee of the great surgeon's entrance into the medical profession. A rapid survey of the contents of the two large volumes before us will suffice to give a notion of the ground covered in them.

Lister's first steps in scientific research were in the domain of physiology. This was a natural result of the influence of Sharpey. Another teacher from whom he learnt much that was to be of the greatest use to him in his life work was Graham, the Professor of Chemistry at University College. From these men and from his father, Joseph Jackson Lister, who discovered the law of the aplastic foci, and who was described as "the pillar and source of all the microscopy of the age," the future reformer of surgery got a training in scientific methods such as fell to the lot of few students of his day. It is not, perhaps, too much to say that without the knowledge of physiology and chemistry and the mastery of the use of the microscope with which he started he would never have been able to build his system on the solid foundation which has made it, however subject to modifications in details, in its essence a truth that cannot be shaken.

His early papers on the contractile tissue of the iris, the muscular tissue of the skin, the minute structure of the involuntary muscular fibre, the flow of the lacteal fluid in the mesentery of the mouse, the influence of the nervous system in regulating the contractions of the arteries, all give evidence, not only of accurate observation, but of determination to see things through his own eyes. His studies on the causes concerned in producing the concentration and diffusion of the pigment in the skin of the frog under varying conditions show great ingenuity in experiment and acuteness of reasoning. The effects on these processes of the application of irritants to the skin and the relation of contraction and relaxation of the blood vessels to the nervous system threw a light on the nature of inflammation which was to guide him in subsequent investigations. A cognate line of research was pursued with regard to the functions of the visceral nerves, with special reference to their inhibitory action. Lister devoted much attention to the coagulation of the blood, especially to the question of the relation between that phenomenon and the condition of the walls of the blood vessels. These early researches display the resourcefulness in experiment the conscientious accuracy in the observation of facts and the caution in inference which mark all his work. He cleared the ground of much positive error, and gathered a large amount of sound material for the solution of this vital problem which was, and must continue to be, of incalculable use to those who came after. His study on the effects of irritants on the web of the frog's foot gave him the key to the mechanism of inflammation in the early stages of the process. He was the first who accurately described the phenomena of stasis of the blood, and the vascular reaction, immediate and later, which followed the application of irritants. He showed that the effects produced upon the circulation

* *The Collected Papers of Joseph, Baron Lister, Member of the Order of Merit, Fellow and sometime President of the Royal Society, Knight Grand Cross of the Danish Order of the Danebrog, Knight of the Prussian Order pour le Mérite, Associé Étranger de l'Institut de France, etc.* In two volumes, pp. 429 and pp. 589. Price 2s. 2s. net. Oxford: At the Clarendon Press. 1909.

by the application of an irritant are twofold—namely, dilatation of the arteries, a purely functional phenomenon developed indirectly through the medium of the nervous system, not limited to the part acted on by the irritant, but implicating a surrounding area of greater or less extent; and alteration of the tissues from the direct action of the irritant, as a result of which the blood in their vicinity loses the properties which characterize it while within a healthy part, and assumes those which it exhibits when removed from the body and placed in contact with ordinary solid matter. He showed further, by experiments on amputated limbs, that the tissues possess, independently of the central organs of the nervous system, or of the circulation, or even of the presence of blood within the tissues, an intrinsic power of recovery from irritation when it has not been carried beyond a certain point. He also pointed out that it was necessary to draw a broad line of demarcation between inflammation set up by direct irritation, and that which is produced indirectly through the medium of the nervous system, "whether in the immediate vicinity of a source of irritation, as around a tight stitch in the skin or a thorn in the finger, or at a distance from the disturbing cause, as when the kidneys are affected in consequence of the passing of a bougie, or the lungs through exposure of the feet to cold."

His final conclusion was that his experiments had established the fundamental principle, that "whenever the disturbance of the circulation which is truly characteristic of inflammation exists in any degree, the tissues of the affected part have experienced to a proportionate extent a temporary impairment of functional activity or vital energy."

This paper was published in 1857, when Lister was Lecturer in the Extra-mural School and Assistant Surgeon to the Royal Infirmary.²⁰ In 1860 he was appointed Professor of Surgery in the University of Glasgow, with charge of wards in the Royal Infirmary of that city. At that time inflammation and suppuration were universally regarded as natural processes in wounds by surgeons who directed their efforts, by means of poultices and other applications, to helping the formation of what was called "laudable" pus. Septic disease was everywhere rife and was the mere despair of surgery. Sir Hector Cameron, who worked under Lord Lister when he made his first attempts in the direction of antiseptics, describing the state of things at that time, says:

Every wound discharged pus freely, and putrefactive changes occurred in the discharges of all, producing in the atmosphere of every ward, no matter how well ventilated, a fetid sickening odour, which tried the student on his first introduction to surgical work just as much as the unaccustomed sights of the operating theatre. It is hardly necessary to add that fatal wound diseases and complications were never absent at any time from the hospitals of that day.

It is worth while to point out that, according to Sir Hector Cameron,

Lister soon began to enjoin on all persons in his clinic the practice of scrupulous cleanliness, which was at that time by no means always a characteristic of surgical practice. The washing of hands was insisted on after dressing each individual case, and large piles of clean towels stood on the tables of his wards for the use of his dressers and nurses.

Lister's work on inflammation, valuable as it was, did not lead him directly to his great discovery. But, unlike the surgeons of that day, he was not content to accept inflammation and suppuration as a necessary part of the process of healing. He believed that the natural course of events was that a wound should heal, like a simple fracture or other subcutaneous injury, without inflammation, suppuration, or septic infection. He recognized that the source of the mischief in wounds was putrefaction, and that the prevention of this should be the aim of the surgeon. The idea was in his mind at the very beginning of his career when he was Erichsen's house-surgeon in University College Hospital. The accepted teaching of the day, that putrefaction was due to the action of the air, particularly of the oxygen, on the organic fluids in wounds, did not satisfy him, and in the various methods of dressing

adopted by him he never made any attempt to exclude that constituent of the atmosphere. As has been said, he insisted on rigorous cleanliness, but his wards were so insanitary that neither this nor frequent changes of dressing, nor careful drainage, nor free washing with warm water and Condy's fluid, availed to check the prevalence of pyaemia, erysipelas, and hospital gangrene. Pyaemia is now little more than a memory to those who have witnessed the gradual diffusion of Lister's teaching. As Sir Victor Horsley said before the Royal Commission on Vivisection, any one who should be asked now to write an article on pyaemia in a dictionary of surgery could not do it, for the disease has ceased to be. The same thing may be said of hospital gangrene. What that fearful scourge was may be learnt from John Bell, who, in his *Principles of Surgery* (1801), says:

When it rages in a great hospital it is like a plague; few who are seized with it can escape. There is no hospital, however small, airy, or well regulated, where this epidemic ulcer is not to be found at times; and then no operation dare be performed! Every cure stands still! Every wound becomes a sore, and every sore is apt to run into gangrene; but in great hospitals especially it prevails at all times, and is a real gangrene. It has been named the Hospital Gangrene; and such were its ravages in the Hôtel Dieu of Paris (that great storehouse of corruption and disease) that the surgeons did not dare to call it by its true name; they called it the rottenness, foulness, sloughing of the sore! the word, hospital gangrene, they durst not pronounce: for it sounded like a death-bell; at the hearing of that ominous word, the patients gave themselves up for lost. In the Hôtel Dieu this gangrene raged without intermission for two hundred years, till, of late, under the new government of France, the hospital has been reformed. A young surgeon (says an ancient French author who is bred in the Hôtel Dieu, may learn the various forms of incisions, operations too, and the manner of dressing wounds: but the way of curing wounds he cannot learn. Every patient he takes in hand (do what he will) must die of gangrene."

What, then, says the same author, speaking of the treatment of hospital gangrene, is the surgeon to do?

Is he to try experiments with ointments and plasters while men are dying around him? Is he to expend butts of wine, contending, as it were, against the elements? No! Let him bear this always in mind, that no dressings have ever been found to stop this ulcer: that no quantities of wine or bark which a man can bear have ever retarded this gangrene; let him bear in mind that this is a hospital disease, that without the circle of the infected walls the men are safe; let him, therefore, hurry them out from this house of death: let him change the wards, let him take possession of some empty house, and so carry his patients into good air; let him lay them in a schoolroom, a church, a dunghill, or in a stable (like Paré's *sic*) gangrened soldier); let him carry them anywhere but to their graves.

These scourges were so prevalent in the Glasgow Royal Infirmary that Lister says he felt ashamed, when recording the results of his practice, to have to allude so often to hospital gangrene and pyaemia, and he came to welcome simple fractures, though of little interest either for himself or the students, because their presence diminished the proportion of open sores among the patients. In other hospitals both in this country and abroad, the state of things was just as bad.

Then came the discoveries of Pasteur which revealed the cause of putrefactive fermentation to be the development of living organisms in the dust of the atmosphere. Lister forthwith applied the new doctrine to the treatment of wounds. By his conviction that the ideal to be aimed at was that a wound should heal like a subcutaneous injury he was led to apply it first in the treatment of compound fracture. The effect was immediate and striking. Not only did repair occur without systemic disturbance, but primary amputation, which before was almost the rule in bad cases of compound fracture, became almost a thing of the past, and not only innumerable limbs, but a vast number of lives were saved. He observed that the crust formed by the carbolic acid applied as a dressing and the blood became organized into living tissue, and that dead bone, instead of being exfoliated, was absorbed. From compound fracture he extended his treatment to psoas abscess, and gradually to wounds of all kinds. Although at a shallow depth under his wards were found a multitude of putrefying bodies of people who had died of cholera in 1849, and who had been buried in pits, he was able to report to the British Medical Association in 1867 that during the previous nine months not a single case of pyaemia, erysipelas, or hospital gangrene had occurred in

²⁰ The portrait reproduced in this issue, which forms the frontispiece of the first volume of the collected papers, is from a photograph taken in 1856.

Lister

his wards. How had this miracle been wrought? It could not be ascribed to mere cleanliness, though that was most strictly enforced; the influence of sanitation was absolutely excluded by the existence of the sources of putrefaction in the near neighbourhood of the wards. This very fact, indeed, formed an *experimentum crucis* that proved that the change was due to the adoption of measures which killed the invisible agents which produced septic disease.

It is unnecessary here to tell, even cursorily, the history of the introduction and development of the antiseptic system. It is enough to say that Lister, taking Pasteur as his guide, studied for himself with characteristic thoroughness the action of micro-organisms in producing putrefactive fermentation in organic fluids and the methods of preventing their development. He then with definite patience tried how the new principle could most effectively be applied to the treatment of wounds. His early methods were crude and cumbersome, and he gave nearly the whole of his professional life to perfecting them.

Although carbolic acid had previously been used in a casual way by some surgeons as dressing, Lister was the first to use it systematically for the prevention of putrefaction in wounds. His attention was directed to it by experiments made at Carlisle on the disinfection of sewage with German creosote in which crude carbolic acid is the active constituent. But, successful as he found it for his purpose, he was careful to warn surgeons that it was not in itself a specific; that the antiseptic system did not consist in the mere use of an antiseptic, however potent, but in "such management of the case as shall effectually prevent the occurrence of putrefaction in the part concerned"; and that the treatment must be based on the germ theory of putrefaction. He insisted that his good results were not due to his personal care, but to the principle on which he worked. To the pains which he took to perfect his machinery, his labours in the improvement of the catgut ligature and dressings, which are related at length in these volumes, and his painstaking and unprejudiced trials of every substance that offered any promise of keeping wounds sweet without causing irritation, bear eloquent witness. We see him ceaselessly striving after simplification of dressings without sacrifice of efficiency.

It may not be superfluous here to point out that the carbolic acid spray is not, as has been imagined by some, the essence of Listerism. The spray was only an incident in the evolution of the antiseptic system; it was used for a few years and then discarded by Lister, who in 1890 frankly declared that he was ashamed he had ever recommended its use. If there is one feature in Lord Lister's character that strikes the reader of these volumes more than another, it is the open-mindedness with which he has tried everything that seemed likely to be of service, and his readiness to confess mistakes.

Listerism, it must be repeated, is not a system of dressing, but a principle. That principle is the exclusion from the wound of all agencies which have the power of causing putrefaction. So far from the aseptic system being, as is still said by some, the negation of antiseptics, it is the logical outcome of the principle on which the antiseptic system was based. The success claimed by certain surgeons who perform abdominal operations without antiseptic means has been, as Lister says, a stumbling-block to some. But, as he pointed out, these surgeons are careful to purify their sponges and wash out the peritoneum so as to clear it of the residual clots in which lies the risk of sepsis. We have seen that Lister himself, before he began his antiseptic work, insisted on scrupulous cleanliness. This in itself was a novelty in surgical practice. Did not Sir Astley Cooper, after removing a tumour from the scalp of George IV, and being in an agony of fear of the superinfection of erysipelas, incur the King's displeasure by appearing before him with his wristbands and his hands stained with the blood of a patient on whom he had operated just before? Years after the Listerian doctrine had begun to permeate the mind of the profession we remember a famous surgeon habitually operating in a coat which a decent butcher would now disdain to use, and another who went through his wards handling all manner of wounds, opening abscesses, and doing all his work without ever going through the ceremony of washing his hands. If such things are almost unthinkable nowadays, that is due to the teaching of Lister.

Less than twenty-five years ago we heard the late Sir John Erichsen publicly state that operative surgery had then reached its final development. There were, he said, three parts of the body into which the surgeon's knife could never penetrate; these were the brain, the chest, and the abdominal cavity. Long ago all these regions have been brought within the range of surgery. This, too, we owe to Lister. The painlessness of wounds is another thing for which mankind has to thank him. When Huxley visited the Edinburgh Royal Infirmary, he summed up his impressions as follows: "What amazes me, Mr. Lister, is the painlessness of your wounds. You have not only banished those awful scourges which used to affect our wards, but you have abolished the pain and suffering associated with wounds and surgery." This leads us to insist on the fact that Lister's beneficent work could not, as he himself declared before the Royal Commission on Vivisection in 1876, have been done without the light and guidance derived from experiments on living animals. That fact alone is a complete justification of vivisection.

Lister's work has by no means been confined to the establishment of the great principle with which his name will always remain associated. In pathology and bacteriology he made valuable additions to knowledge. In the province of surgery his writings include masterly essays on amputation, on excision of the wrist, on the wiring of fractured patella, on anaesthesia, in which he always took a special interest, and many other things. Years before the introduction of Esmarch's bandage he produced bloodlessness in limbs on which he was to operate by elevating them and applying a tourniquet. In 1870 he stated that for some years he had been in the habit, after removal of the breast for scirrhus, of clearing out the axillary glands after division of both pectoral muscles. The modern methods of treatment of spinal abscesses and diseased joints, of ununited or malunited fractures, and other operative procedures, have to a large extent been directly initiated by Lister. In many other directions he might have claimed, had he cared merely for fame, to be the pioneer. Of the procedures to which his principle finds ever new applications, it is needless to speak. The influence of his teaching is felt through the whole domain of surgery, and will continue to make possible its expansion to an extent undreamt of even now.

In the third Huxley Lecture delivered before the Medical School of Charing Cross Hospital on October 2nd, 1900, which is republished in the second volume, Lord Lister himself gives a most interesting summary of his work, from the time of his researches in physiology to his final victory over the hospital scourges which so often brought the work of the most skilful surgeons to nought. He worked with a first-rate microscope which the labours of his father had placed in the hands of scientific men. While he was still house-surgeon under Erichsen he made original investigations on pathology.

It was by Sharpey's advice that he went to Edinburgh—a visit which was to have such a lasting influence on his after-life. He was fascinated by the prominence given by Syme to the pathological side of surgery, and he was struck by the superiority of the treatment of recent wounds which he witnessed in that great surgeon's wards over the "water dressing" used at University College Hospital in accordance with the teaching of Robert Liston, who introduced it in place of what he called "filthy unguments." He married Syme's daughter, and a graceful tribute is paid in the introduction to the help which Lady Lister throughout her life gave him in his work.

The work here imperfectly reviewed shows the greatness not only of Lord Lister's intellectual achievements, but of his character. It is a record of patient labour, of self-sacrificing devotion to duty and of absolute honesty of purpose which has scarcely a parallel in human history. No man that ever lived has done so much for the relief of physical suffering. He has had the rare good fortune to live to see his labours bearing good fruit all over the world. He has received awards and distinctions such as fall to the lot of few, but those who know him best will readily believe that no dignities or honours can in his eyes compare with the consciousness that he has deserved well of his fellow men. His life may be summed up in the words, *Pertransiit benefaciendo et sanando*.

Reviews.

OBESITY, GOUT, DIABETES.

We have received the seventh and eighth portions of Professor von Noorden's collected clinical essays, which deal with the metabolism of fasting, with overfeeding and its converse the treatment of obesity, and with gout.¹ The first lecture treats of fasting, a subject which is well worthy of careful study, as its phenomena are not as well known as they should be, and this ignorance has led to mistakes; for example, the presence of acetone in the urine is normal in fasting, while the diminution of chlorides noted in many diseases has been simply due to the use of milk diet. Partial fasting is extremely common in disease, and may be voluntary or involuntary, and is a valuable means of treatment in certain conditions, for instance, in nervous anorexia, where complete abstinence from food for a few days is an effectual way of restoring the appetite. Fasting diminishes thirst; professional fasters drink only from 400 to 500 c.c.m. of water daily (12 oz. to 15 oz.), the loss of weight during fasting is not constant, and this may be due to the introduction or retention of water. Fasting, as a rule, proves fatal when 35 to 40 per cent. of the body weight has been lost, but in certain chronic diseases the diminution may reach 40 or even 50 per cent., as in the case of a lady aged 40, who weighed 140 kg. (20 st.), but reduced herself by diet to 11 st. 6 lb., when she developed pulmonary phthisis and died in six months, weighing at the time of her death only 46 kg. (6 st. 8 lb.). In the second lecture he discusses the cures by overfeeding with which we generally associate the names of Weir Mitchell and Playfair. He gives useful tables of diets calculated to allow an excess of about 1,000 calories over that required for the patient at rest. The result of overfeeding is only to fatten the patient, and does not increase muscle so long as the patient is kept in bed. Neither can massage effect this, but if judicious exercise is combined with overfeeding, then muscular development will take place. He strongly approves of putting the patients to lie out-of-doors instead of shutting them up in a room; and as soon as they are able to leave their beds they should begin to walk uphill or cycle or practise regulated gymnastics. Baths and other hydropathic means are helpful, but he protests against the exaggerated value attached in Germany to drugs, "where a cacodylate injection is regarded as of higher value than a beefsteak." The third lecture treats of obesity. He uses systematic diets containing only from 2,000 to 1,000 total calories. The amount of water drunk is not in all cases to be limited, but "by this means polyphagia may be inhibited." Treatment must be checked by the results of systematic weighing and measuring. He attaches importance to muscular exercise by hill-climbing, cycling, tennis, fencing, swimming, or gymnastics, but he does not think riding of much value—an opinion contrary to the universal experience of all nations. Mineral waters may help with regard to complications, but otherwise are "of no more value than a drop of water on a hot stone." Sweating may remove water from the body, but CO₂ baths are useless and are dangerous if the blood pressure is raised. In the last-named condition he prefers to begin treatment by bleeding the patient. The value of cold douching and of thyroid feeding are recognized. The last lecture is devoted to gout, which is remarkably infrequent in Vienna as compared with Frankfurt, where Professor von Noorden practised until three years ago. He holds to the belief that the retention of uric acid is the characteristic of gout, and in order to determine the gouty nature of doubtful affections of joints or nerves he estimates the retention of uric acid by first putting the patient upon a purin-free diet and observing the amount of uric acid still excreted after three or four days, which is what he calls the endogenous uric acid; a definite allowance of meat is then added to the diet, and the result noted; in gouty persons the uric acid is not increased, in others the addition is followed by a rise in the uric acid excretion. Strict diet for gouty persons

should consist of milk, eggs, and vegetables, but purin-containing foods may be added to the extent tolerated; given in carefully measured quantities, as we allow carbohydrates to a diabetic. Alcohol is held to be always injurious to gouty persons. Mineral waters are more useful in uric acid lithiasis than in gout; thymine acid is valuable as a solvent, but should be used in short courses lasting not longer than eight days. As will be seen the essays contain most interesting matter, but no very startling novelties.

We reviewed Dr. LORAND's pamphlet on the rational treatment of diabetes² when the first edition was published (1903, vol. ii, p. 1468). He is a physician practising at Carlsbad, and the rational treatment he recommends consists in diet, mineral water, and organotherapy. He believes that not only the pancreas, but the thyroid and the pituitary body, are concerned in diabetes; he holds that there is an antagonism between the thyroid and the pancreas, and he alludes to the cases of diabetes associated with Graves's disease in support of his view that overaction of the thyroid may give rise to glycosuria. He thinks, further, that eating meat stimulates the thyroid, hence people predisposed to diabetes, and the children of diabetics especially, should eat meat sparingly. He tried to investigate this question by removing the thyroid glands from three dogs who had been depancreatized by Professor Minkowski, but they died so quickly that the conclusions were not certain, although the glycosuria seemed to disappear. He thinks that diabetes may arise spontaneously, in persons who eat meat largely, and that it is a "poison" for diabetics. He goes so far as to say (p. 25):

It is my conviction that it were better for a diabetic to observe no diet at all and to take plenty of carbohydrate food than to confine himself to a strict diet of albumen, fat, and green vegetables for a long period. It is probable that in the former case he would live longer. It is not to be doubted that the observance of such a strict diet, to the exclusion of small quantities of carbohydrates, hastens the development of acidosis and shortens the life of the diabetic.

He is also of opinion that when carbohydrates are taken they are better tolerated if no meat is eaten at the same time. He says:

It is my firm conviction that severe diabetes does better on a milk and vegetable diet and lives longer than on meat diet (p. 24).

He consequently approves of van Noorden's oatmeal cure, yet, in spite of these paradoxical opinions, he insists upon the importance of not overlooking diabetes, and says that it is quite as important a disease as small-pox or tuberculosis, and that there ought to be municipal laboratories, where the urine of everybody could be compulsorily examined. He uses thyroid extract, or rather Kocher's thyraden and Moebius's antithyroidin, the former for severe and the latter for mild cases, and claims that he has cured a case of diabetic coma by the use of thyroid preparations. He thinks goat's milk, and especially that of goats from which the thyroid gland has been removed, best suited for the treatment of diabetes.

THE UPPER AIR PASSAGES.

FIFTEEN years have elapsed since Dr. Moritz Schmidt published his well-known treatise on the diseases of the upper air passages. It was at once recognized not only as a thorough exposition of recent knowledge, but also as bearing the impress of the personality of its author, who took for his motto the words, *Aus der Praxis, für die Praxis*, and throughout the work emphasized the lessons of practical experience for future use in practice. It was his expressed wish that the present editor of the new edition, Professor EDMUND MEYER, should carry on the work on the same lines, but with a free hand as regards individual opinion. Dr. Meyer undertook the work with some reluctance, owing to the fact that in many important points, both practical and theoretical, he and Dr. Schmidt had not seen eye to eye. Maintaining the same form and system, he has produced a book of the greatest practical value and historic interest. In the world of laryngology and rhinology history has been making itself space in the last decade, and a comprehensive work must needs be a

¹ *Sammlung Klinischer Abhandlungen über Pathologie und Therapie der Stoffwechsel- und Ernährungsstörungen.* Herausgegeben von Professor Dr. Carl von Noorden. Hefte 7 und 8. Ueber die Behandlung einiger wichtigen Stoffwechselstörungen (Hungerzustand, Mastkuren, Entfesselungen, Gicht.) Berlin: August Hirschwald, 1909. (Roy. 8vo, pp. 104, M. 2.00.)

² *Die Rationelle Behandlung der Zuckerkrankheit.* Von Dr. A. Lorand. Berlin: August Hirschwald, 1909. (Med. 8vo, pp. 60, M. 1.60.)

large one. Considerations of space have necessitated the omission of many references, but the use of bold type and the addition of a very full index render reference easy.

Dr. Schmidt did not live to see the completion of this edition, which would doubtless have been recognized by him as a worthy exposition of modern knowledge and thought on the subjects to which he had devoted so much of his life's work. Knowledge, even of the anatomy of the upper respiratory passages, has been steadily advancing, and with it the means of effective treatment. The introduction of better means of illumination has greatly assisted diagnosis, and within recent years the method of direct examination of the larynx and trachea has begun to take shape and to rank among the feasible adjuncts to successful treatment in suitable cases. The constant liability of the nose and larynx to injury or infection from without calls for the oft-repeated warning as to the disadvantages and dangers of over-coddling. Such warnings too often fall upon deaf ears. The "comforter" and the habit of wrapping up the neck by both sexes is still the commonest cause of the "delicate throat."

The immense importance of accurate diagnosis of affections of deep-seated parts cannot be overrated, and even among experts unanimity as to actual conditions cannot always be arrived at. The introduction of the electric lamp into the hidden cavities of the air passages has already done much, and may yet do more, to clear up doubtful points. The latest forms of instrument for this purpose are clearly described and demonstrated.

The general consideration of the diseases of the upper air passages follows the lines adopted in the first edition. Acute and chronic inflammations are exhaustively described. New methods of treatment—as, for instance, the submucous injection of paraffin in cases of ozena, to restore the internal constriction of the nasal passages, and vibratory massage within the nostril—are duly commented on and their relative values indicated. Affections of the naso-pharynx and tonsils are fully dealt with, and a description given of the special form of angina described by Vincent in 1898. The fusiform bacilli in association with spirilla, which he found in these cases, have been recognized by others, although many have failed to detect them. The accessory sinuses have been attacked by modern surgeons with ever-increasing boldness, and an account of all that has been achieved in this field of surgery and of the arguments for and against some of the most recent methods should be read by those who wish to preserve an open mind on the subject. Tubercle is an ever-present danger to the larynx, and the importance of its early recognition must always be emphasized. Even in the more advanced cases the former pessimistic views must now give place to a more hopeful outlook. The bolder use of endolaryngeal surgery and the occasional employment of laryngotomy have done much to relieve, if not to eradicate, the further progress of the disease. As in the case of tubercle, so also in the treatment of syphilis, lupus, diphtheria, and other less common infections, substantial advances have been made, and we cannot too warmly commend to the notice of all progressive workers in this department the admirable work in which the practical teaching of the late Professor M. Schmidt has been carried forward and amplified by his distinguished successor.

EXPERIMENTAL EMBRYOLOGY.

The discovery of the causes which determine the specific form in the race and in the individual is a matter of intense interest to all biologists. Many methods have been tried by those who would solve the problem, and present-day biologists are attempting to discover the secret by means of experiments on living embryos. Experimental embryology has thus become a new branch of biological science, and Dr. JENKINSON'S monograph on the subject¹ is an excellently conceived and admirably executed attempt to place on record a summary of the more important work which has hitherto been done and the conclusions which may be deduced from it. The

author describes in considerable detail the experiments which have been made upon cell division and cell growth—the effects of external factors, such as gravity, mechanical agitation, electricity, light, heat, atmospheric pressure, osmotic pressure, and the chemical composition of the media in which development occurs. The effect of internal factors forms the subject of another chapter; and the concluding section is devoted to Dreisch's theories of development which are introduced apparently more with the hope that they may serve as working hypotheses than in the belief that they explain all the known facts. The story of the work which has been done is fascinating, and, as set forth by Dr. Jenkinson, well repays perusal, but when the last page is turned the reader will be convinced that the end of the subject is yet far away. There was a period when preformation gained universal belief. Then epigenesis held sway. Later came the mosaic theory of Roux and Weismann's elaborate conception of the capabilities of the constituents of the chromosomes; both the latter views involved the belief that every inheritable quality of the body has its own definite representative in the germ. Once again the pendulum is swinging, and, if we understand Dr. Jenkinson correctly, it is inclining towards the combination of preformation and epigenesis, for he appears willing to accept Dreisch's theory so far as it postulates a simple original organization of the germ, which, however, though it is "simple enough to allow of divisibility of the whole into totipotent parts," is still "complex enough to account for the limitation of the potentialities of these parts, which, sooner or later, inevitably ensues"; for the idea of complete morphological preformation *ab origine* Dr. Jenkinson would substitute "the successive preformation by the action of the parts on one another in the organs of each stage of the structures that are to be developed out of them in the next."

HOLIDAY RESORTS.

WE have received a handbook published by the authority of the District Council of Cullen, which has of recent years become a favourite summer resort. Possibly many of our readers are not aware of the existence of this small town, which is situated on the Banffshire coast, and for the purpose of Parliamentary representation forms one of what are known as the Elgin District Burghs. Cullen is a town of about 2,000 inhabitants, largely composed of fisher people who reside almost exclusively in a part of the town by themselves. The chief attractions claimed by Cullen as a holiday resort are the combinations of sea and woodland; there is a fine open, sandy beach, with facilities for bathing, and a golf links with a course of eighteen holes. The surrounding country affords ample opportunities for pleasant cycling and walking tours: while for those who are not disposed for active exercise the grounds of Cullen House, the residence of the Dowager Countess of Seafield, are open to visitors several days in the week. Cullen may be confidently recommended as one of those places which have not yet succumbed to the conventional features of the modern watering place. It is a place where a hard-worked medical man may find a bracing and pleasant resting place after a heavy winter's work. Cullen is easily reached either from Aberdeen or Inverness. The small handbook is published by Doubleday and Co., 8, York Buildings, Adelphi, W.C. The passenger superintendent of the North of Scotland Railway—Mr. Deuchar—will give full particulars of route and also a list of lodgings.

Another handbook published by the same firm and also under the authority of the Burgh Council, refers to Kirkcubright, which is situated at the other end of Scotland, on the banks of the Dee, the estuary of which stretches out into Kirkcubright Bay. The situation of the town is beautiful; it is surrounded by finely wooded hills, and the climate is warm and soft. It has an ample supply of excellent water. Many places of interest abound in the neighbourhood, Lochgerris, St. Mary's Isle, scene of one of the exploits of Paul Jones. The hotel and house accommodation is good. There is a golf course of nine holes and a bowling green; boating may be had, and fishing in the neighbouring streams can be obtained by arrangement. Kirkcubright is reached by the Glasgow and South-Western Railway, and for those coming from the South there is a connexion with the Midland Railway. Kirkcubright should be a place well suited, on account of its balmy atmosphere, for elderly invalids who desire rest and quiet.

¹ *Die Krankheiten der Oberen Luftwege*, by Moritz Schmidt. Fourth edition, edited and enlarged by Professor Dr. Edmund Meyer, of Berlin. Berlin: Julius Springer. 1909. 48 pp. roy. 8vo. pp. 782; with 180 figures in the text, a portrait, and 5 coloured plates. M. 22.

² *Experimental Embryology*. By J. N. Jenkinson, M.A., D.Sc. Oxford: The Clarendon Press; and London: H. Frowde. 1909. 62 pp. 8vo. pp. 349, figures 167. 12s. 6d.

It may be objected, perhaps, that *Tourists' Guide to the Continent*⁵ is somewhat of a misnomer for a book which merely relates to parts of Holland, Germany, Austria, Switzerland, and Scandinavia, but otherwise the conception of the volume issued by the Great Eastern Railway Company and edited by Mr. Percy Lindley is excellent. Its object is to show the places on the Continent which can readily be reached by the service of this company, and to indicate the facilities offered at each principal centre for exploring the country more or less in its immediate neighbourhood. An endeavour, moreover, has been made to pick out places which at present are little known to tourists. It is certainly true that the traveller who reaches the Continent at the Hook of Holland finds himself in touch with much more comfortable traffic arrangements than at many other ports: and this fact, apart from the clear letterpress and the excellent pictures in this guide, should be sufficient to lead many prospective travellers to choose the Great Eastern route. The volume concludes with a vocabulary of useful phrases in English, French, and German.

A publication of corresponding kind is the illustrated *Guide to the London and South-Western Railway*, but it is of a less ambitious character, inasmuch as it deals merely with places in England easily reached by this railway. Their attractive points are brought out briefly in the letterpress, and in addition there are ample lists of hotels, boarding houses, and apartments, with the prices charged, and a note as to their distances from the railway station and other particulars. A list of golf links also finds place. This guide can be obtained, we understand, free on application at any of the stations or agencies of this line, and should be useful to those with thoughts bent on a week-end or longer holiday.

*To and Fro*⁶ is a publication which purports to save its purchaser time and money by showing him how to go from anywhere to anywhere in London. Directions for its use are supplied in English and several other languages. After studying these indiscriminately but steadily, we made several attempts to apply them, and finally concluded that this work was not likely to prove a serious rival to the local policeman as a guide and counsellor to the wayfarer, but that, on the other hand, it was worthy of consideration by those who find a Continental Bradshaw an attractive intellectual exercise. One of its features is a "Location Directory," which is apparently intended to be a guide to the principal houses of business, places of amusement, and the like. Included in it are two short lists of physicians and surgeons respectively. In neither case are the majority of them persons known, as far as we are aware, to any one but those in their immediate neighbourhood and their personal friends and patients. If the rest of the guidance as to principal places is of the same character, it is clear that the publication might be less useful than its compilers suppose. An intention is indicated to make this directory a monthly publication, but in humble imitation of its polyglot introductions we are disposed to say on this point. Wir wollen sehen! Nous verrons! Bakaloum! or in plain English, We shall see.

NOTES ON BOOKS.

The Family Doctor,⁷ by Dr. EDMUND BARRETT, bears a kind of family resemblance to a publication very popular some thirty years ago, which purported to give information about everything in a series of alphabetical notes. In this case the information is confined to short explanations of terms common in connexion with the ills to which human flesh is subject. Possibly there may be some utility in a volume of this order, but the selection for notice of a certain number of proprietary articles tends to give a dubious character to the whole book.

The Socialist,⁸ by GUY THORNE, seems to be a novel with a purpose, but whether intended to guide the reader to the conclusion that the claims of socialism are well founded or the reverse is not certain. The principal hero turns out, we understand, to be a churchman in disguise, and the principal heroine retires to assume the duties of maternity. It is on the whole well written.

⁵ *Tourists' Guide to the Continent*. London: 39, Fleet Street. (Pp. 319. Price 6d.)

⁶ *To and Fro*. Simpkin, Marshall. Price 6d.

⁷ *The Family Doctor*. By Edmund Barrett, M.B., B.S. Durham. London: George Routledge and Sons. 1909. (Pp. 329.)

⁸ London: Ward, Lock and Co. 1909. (Post 8vo, pp. 320. 6s.)

Thirty years ago Lieutenant-Colonel JOSHUA DUKE, then a comparatively young officer in the Indian Medical Service, wrote *Queries at a Mess Table*, and at the request of his publishers has now brought the book up to date.⁹ In spite of its small compass it contrives to supply a good idea of the more important characteristics of the foodstuffs and liquids which commonly figure on regimental and club dinner tables all over the world, and may claim to be a sound guide to men who wish to steer between eating to live and living to eat. General hints on the preservation of health and activity are also given, and with one exception are of a very useful kind. The exception is the unqualified condemnation of belts and kummerbunds. In one form or another these are worn by the inhabitants of tropical and semi-tropical climates all over the world, and this is a strong argument in their favour. They are superfluous in Europeans, when custom or duty necessitates covering the body and limbs with several layers of clothing, but on other occasions one would have thought their utility beyond dispute. The wearer of a belt can safely clothe the rest of his body as lightly as he pleases or as decency permits.

⁹ *Queries at a Mess Table: What shall I Eat? What shall I Drink?* Second edition. London, Calcutta, and Simla: Thacker and Co. 1908. (Fcap. 8vo, pp. 107. 1s. 6d.)

MOTOR CARS FOR MEDICAL MEN.

COST OF RUNNING.

DR. SAMUEL CRAWSHAW (Ashton-under-Lyne) sends the following notes on the actual cost of running a Ford 15-h.p. car for twelve months: The Ford is a car of American make, and mine was delivered to me on March 31st, 1908. Since then it has done all my work, and I have had about 1,500 miles of driving for pleasure in addition. I estimate the total mileage at 9,000; over half of this has actually been recorded and the other half carefully estimated. I have never once been stopped on the road for any mechanical trouble, and never turned out without getting home again on the car without the slightest delay, except when punctures have occurred. I selected the Ford car after very careful tests at the 1907 Olympia Show of it and six or eight other makes, and in my opinion it is one of the best designed and cheapest cars on the market for medical men. It is one of the most accessible cars—a very important matter—and contains many simple and novel features. I can crawl along on top speed at about 5 miles an hour, or go at any speed up to 35; and I can climb hills on top speed up to a gradient of 1 in 15.

Running Costs for Year ending March 30, 1909.

Petrol (519 gallons)	£27 10 0
Repairs and renewals	28 18 5
Tires	15 9 10
Oil and grease	5 0 0
Sundries	3 5 0
	83 3 1

9,000 miles = 2.14d. per mile.

Fixed Charges for Year Ending March 30th, 1909.

Chauffeur	£76 14 0
Stable rent, coal and gas	10 3 0
Licences	2 2 0
Insurance	12 15 6
Depreciation at 25 per cent.	59 0 0
Loss of interest at 3 per cent.	7 0 0

9,000 miles = 4.47d. per mile.

Total cost per mile, 6.61d.

£167 12 6

I have used 519 galls. of petrol, giving an average of 17.345 miles per gallon. On a pleasure run, about 70 miles I have on two occasions found the consumption to be 27½ and 28 miles per gall. respectively, but with the constant stopping, starting and reversing, that working a practice entails, the petrol consumption rises very considerably.

Repairs to the extent of about £2 4s. have been necessitated by several slight accidents, and another item of £3 was occasioned by the breaking of a ball in one of the front wheel bearings, which, before we had noticed it, had cut up the cones and ball races and deeply scored the arm. The other items are due to various small breakages and cost of labour in repairs, adjustments, and overhauling. My first set of tyres (five in number) ran about 4,300 miles each. During the year I have had two new tyres and one new tube. The first set of tyres have been retreaded. I consider that I have quite 2,000 miles left in the tyres yet.

I have estimated depreciation at 25 per cent., but perhaps this is excessive, as the car would still be worth something at the end of four years.

In addition to these items I have recently spent a little on what should be regarded as capital account—namely, a single trembler coil, which is really a great advantage, and a Bowden extra air inlet valve, with which I hope to improve the petrol consumption.

DR. W. V. FURLONG (Dublin) writes: As many of the accounts of your correspondents regarding the cost of running, repairs, etc., of their motor cars are, from my experience, far too rosy, I give, for the benefit of my brother practitioners, my first year's working, ending to-day:

10-12-h.p. Siddely, hood, screen, magneto, etc.	£375 0 0
Stepney wheel, extra lamps, and sundries	27 11 2
	<hr/> £402 11 2

Repairs for year (not including those covered by insurance)	£11 0 11
Tyres, tubes, and repairs to same	15 0 7
Petrol (181 gallons)	9 16 5
Lubrication	1 16 6
Insurance	11 10 0
Registration and licence	1 5 0
	<hr/> £50 9 5

Miles travelled 2,460, or about 15 miles to the gallon. The car was on the road and in good working order 120 days during the twelve months.	
Cochman's wages	60 0 0
	<hr/> £110 9 5 and capital £402 11 2

Yearly cost, excluding garage

The Siddely is a good strong car, but the time lost waiting for trivial repairs and in obtaining the correct parts wanted through the agents prevents a doctor from depending on a motor car unless he keeps horses as well, or a few other motors to be ready at hand. I probably have been particularly unfortunate, as my motor has only been able to do a third of my work for the year, nor can I get more than fifteen miles out of a gallon of petrol.

SOMERSET writes: I should be interested to learn what happens to the gallon and a half of oil and the pound of grease which "T. D. N." uses on a 10-12 Swift every week. From a year's experience of this excellent car I have found no need to use oil to this great extent. The engine lubrication is by a hand-pump on the dash, and the makers informed me that one charge every ten miles was sufficient, the pump delivering about 2 oz. of oil at each charge; with a mileage of 245, this accounts for 50 oz. a week. There are only seven grease cups on the car, and 1 oz. or so of grease will easily fill them, and it is only necessary to give each a turn daily to ensure proper lubrication. During the past twelve months my car has travelled 7,000 miles, and has used about 10 galls. of oil and 5 lb. of grease.

As to tyres, I have worn out two pairs of steel-studded covers on the back wheels, each lasting approximately 3,000 miles, and then being retreaded. One grooved front tyre lasted 4,500 before retreading; the other is still in use, and looks good for some little distance yet. It is interesting to note that the front cover which first failed had been run for a time with a detachable non-skid band, bearing out "Wiser's" contention that these diminish the life of the covers. At present I have grooved covers on all wheels, and fit a Parsons's chain when the roads are greasy. It is only fair to say that my car has a side-entrance body, with hood and screen, and must weigh, when loaded, fully a ton.

I am so satisfied with this particular make as being a first-class car at a reasonable price that, requiring a second vehicle, I have this week ordered a two-seater of the same power with dual ignition.

MEDICAL BAG ON MOTOR CYCLE.

J. D. asks hints as to the best way of carrying instruments, bottles, etc., on a motor cycle.

LITERARY NOTES.

A COMMITTEE has been formed at Athens for the publication of all the works of ancient Greek writers on medicine, both those which have already been issued and those which have never seen the light. The chairman of the committee is M. Konstantinos Kontos, professor of Greek literature in the University of Athens; the other members are Dr. Konstantinos Samaras, assistant professor of gynaecology in the university, and MM. Rossin and Charitonides, doctors of letters and professors of Greek literature at Athens.

Miss Gertrude Toynebe has published, through Mr. Henry J. Glaisher, a brief but charming account of the intellectual tastes and character of her father, the distinguished aural surgeon, Joseph Toynebe. He was fond of poetry; the elder Arnold, Dean Stanley, Frederick Robertson, of Brighton, and William Ellery Channing were all writers with whom he had much sympathy. As a young man he was deeply interested by Emerson. He watched with keen interest the progress of scientific thought. He had an ardent love of nature and enjoyed all kinds of scenery. He worked for the improvement of the physical and intellectual condition of the poor, and started a Samaritan fund for the provision of food for the

indigent. He also helped to found the Metropolitan Association for improving the Dwellings of the Working Classes, and wrote leaflets for the instruction of the ignorant in matters pertaining to health. In other ways he was active in promoting the welfare of the poor. He was a lover of art and a collector of water colours. In summing up her father's character, Miss Toynebe says that its distinguishing feature was his personal magnetism. He drew all kinds of people to him by his sympathy, charm, and sincerity.

Messrs. Churchill will publish in a few days a new edition of *Minor Surgery and Bandaging*, revised by Mr. Bilton Pollard, Surgeon to University College Hospital. The first edition of this work, by Mr. Christopher Heath, was issued 48 years ago. The present (14th) edition has been enlarged by nearly a hundred pages, and contains many new figures, and a frontispiece of a surgeon in aseptic operating costume. They will also issue an *Atlas of Dental Extractions, with Notes on the Causes and Relief of Dental Pain*, by Mr. C. E. Wallis, Assistant Dental Surgeon, King's College Hospital. The text will be supplemented with a series of illustrative plates.

In an article by Dr. James J. Walsh, Dean and Professor of the History of Medicine and of Nervous Diseases at the Fordham University School of Medicine, New York, entitled "Old Documents in Medical Educational Practice," published in the *Dublin Journal of Medical Science* for December, 1908, it is shown that medical education in the Middle Ages was more advanced than is usually supposed. One of these documents is a bull of Pope John XXII founding a school of medicine in the University of Perugia; the other is a law issued for the two Sicilies by the Emperor Frederick II. Both serve to show that a high standard of knowledge was required of the physician, and that care was taken to enforce the proper course of study and to prevent unqualified persons from teaching or practising medicine. According to Pope John's bull, which is dated February 18th, 1321, students of medicine had to go through three years of preliminary studies before beginning the five years' medical training. The first professors were to be graduates of medicine from the Universities of Paris and Bologna, then looked upon as the leading medical schools; and they were to occupy all the masterships and professional chairs at the new university for four or five years, until some of their pupils should be qualified to take them. The right of conferring the licence to teach (the Doctorate) was given to the Bishops of Perugia. The candidate who sought the degree of doctor was presented to the Bishop or his representative, who thereupon appointed four examiners. It was enjoined that these examiners,

without any charge to the candidate and every difficulty being removed, should diligently endeavour that the candidate be examined in science, in eloquence, in his mode of lecturing and anything else which is required for promotion to the degree of doctor or master. With regard to those who are found worthy, their teachers should be further consulted privately, and any revelation of information obtained at such consultations as might redound to the disadvantage or injury of the consultors is strictly forbidden. If all is satisfactory, the candidates should be approved and admitted and the licence to teach granted. Those who are found unfit must not be admitted to the degree of doctor, all leniency or prejudice or favour being set aside.

The law of Frederick II regulating medical practice was issued about the year 1240, and deals with every detail of professional life. None could practise medicine

except such as have beforehand in our University of Salerno passed a public examination under a regular teacher of medicine and been given a certificate, not only by the professor of medicine, but also by one of our civil officials, which declares his trustworthiness of character and sufficiency of knowledge.

This certificate had to be presented to the Emperor or his representative by any one who wished to obtain a licence to practise; any infringement of this law was punishable by confiscation of goods and a year's imprisonment. Stringent rules were laid down as to the length of the medical curriculum and the subjects comprised therein. No student was allowed to study medicine unless he had spent three years in the study of logic, which at that date included practically all the subjects comprehended within the sphere of the arts department of a modern university.

Five years had to be spent in medicine, and the student was obliged by law to study surgery at the same time. No one might practise unless he had, after the expiration of the five years' course, "during a full year devoted himself to medical practice with the advice, and under the direction of, an experienced physician." Then, and only then, could the licence to practise be obtained. The law for surgeons was equally severe. No surgeon was allowed to practise without a written certificate.

stating that he has spent at least a year at that part of medicine which is necessary as a guide to the practice of surgery, and that, above all, he has learned the anatomy of the human body at the medical school, and is fully equipped in this department of medicine, without which neither operations of any kind can be undertaken with success nor fractures be properly treated.

Professors in the medical schools were bound to teach both practical and theoretical medicine and to "devote themselves to the recognized books, those of Hippocrates as well as those of Galen," and no one might teach or lecture on medicine or surgery without previously having passed a searching examination in the presence of a professor of medicine and a Government official. Nor did the legislator forget the pharmacist. Two inspectors were appointed in each province of the kingdom to inspect all drugs and medicines, and to see that they were prepared according to law; no druggist was allowed to sell his goods until they had undergone this examination. In Salerno the inspectorship was limited to those who had taken their degrees as masters in physic; but besides these public inspectors every practising physician was bound by oath to report an apothecary who sold drugs "of less than normal strength." The greatest possible care was taken that the drugs should be pure, and the following regulation is said by Dr. Walsh to be the first law enforcing the purity of drugs:

Apothecaries must conduct their business with a certificate from a physician according to the regulations and on their own credit and responsibility, and they shall not be permitted to sell their products without having taken an oath that all their drugs have been prepared in the prescribed form, without any fraud. The apothecary may derive the following profits from his sales: Such extracts and simples as he need not keep in stock for more than a year, before they may be employed, may be charged for at the rate of 3 tarrenes [3s. 6d.] an ounce. Other medicines, however, which in consequence of the special conditions required for their preparation, or for any other reason, the apothecary has to have in stock for more than a year, he may charge for at the rate of 6 tarrenes an ounce. Stations for the preparation of medicines may not be located anywhere but only in certain communities in the kingdom as we prescribe below. We decree also that the growers of plants meant for medical purposes shall be bound by a solemn oath that they shall prepare their medicines conscientiously according to the rules of their art, and so far as it is humanly possible that they shall prepare them in the presence of the inspectors. Violations of this law shall be punished by the confiscation of their movable goods. If the inspectors, however, to whose fidelity to duty the keeping of the regulations is committed, should allow any fraud in the matters that are entrusted to them, they shall be condemned to punishment by death.

All business relations between doctor and apothecary were strictly forbidden, and no licensed physician was permitted to keep an apothecary's shop. The physician's fees were also regulated by law. He was obliged to treat the poor for nothing, but for other patients there was a fixed rate of payment:

A physician shall visit his patient at least twice a day, and at the wish of his patient once also at night, and shall charge him, in case the visit does not require him to go out of the village or beyond the walls of the city, not more than one-half tarrene in gold for each day's service (about 7d.). From a patient whom he visits outside of the village or the wall of the town, he has a right to demand for a day's service not more than 3 tarrenes, to which may be added, however, his expenses, provided that he does not demand more than 4 tarrenes altogether.

Such are the main points of what may be called the first Medical Act. It is a striking proof of the administrative genius of Frederick, who, occupied with wars and intrigues and all the business connected with his vast and troubled empire, yet understood the importance of medical science so well as to leave this proof of his interest in it. It is not so surprising to find Pope John manifesting an interest in medicine. Not only were the great medical schools of Bologna and Ferrara situated in the papal

States, but the professorships in the papal medical school at Rome were held by famous men, such as Columbus, Eustachius, Varolius, Coesalpinus, Malpighi, and Lancisi. The list of the popes' private physicians includes the names of the most distinguished representatives of medical science of their day; we need only mention Richard the Englishman, Taddeo Alderotti, Simon Januensis, Arnold of Villanova, Guy of Montpellier, and Guy de Chauliac.

In a paper republished from the *Proceedings of the Society of Antiquaries of Scotland*, vol. xxxvii, there is a very interesting account by the late Dr. William W. Ireland of a visit, made by him in company with Mr. W. C. Maughen, to the island of Eileach-au-Naoimh, off the coast of Argyllshire. This island he held to be none other than the island of Hinba or Himba, so frequently mentioned by Adamnan in his life of Saint Columba. According to this authority the saint founded a monastery on this island, at the head of which he placed his maternal uncle Ernau, somewhere between A.D. 563 and 574. This monastery seems still to have existed when Adamnan was Abbot of Iona, A.D. 679-704; but about the beginning of the ninth century the monks were massacred or driven away by the Northmen, and there is no proof that they ever returned. It is true that Fordun, in his *Chronica gentis Scotorum*, written 1441-7, mentions that there was a sanctuary on the island of Eileach-au-Naoimh (which he calls Heland Leneow), but he does not say if it was inhabited. All trace of the island of Hinba seemed to be lost, for none of the Hebrides bears such a name, which is derived from the Gaelic "Imbach" or "Imbeh," signifying "a surrounding sea." But in 1824 Dr. Macculloch visited the Garvelloch Islands, and in Eileach-au-Naoimh, "the mounds of the saints," or "holy mounds," he discovered the remains of some very ancient religious buildings and monuments. The island was uninhabited, and the question arose whether it could be the lost Hinba. Skene believed that it was, and Dr. Ireland held the same view. He describes Eileach-au-Naoimh as a rocky islet about 1½ miles long, with ½ mile as its extreme breadth, and its highest peak, Dun Bhrèanain, or St. Brandon's hill, about 270 ft. high. A column of rock, standing out on the southern shore, is called the Crauogg, or Columba's pulpit. The building supposed to be the ancient chapel stands on high ground, overlooking the sea. Though roofless its walls are entire, built of flat, wide stones laid one upon another without lime, and taken from the rocks around. There is a little splay window at the east end, and on the west side can be seen the traces of a square enclosure. A little way from the south side is an underground cell, with two stone shelves, probably used for storing the wine for the altar. The building known as the Kiln stands higher up the hillside, and is smaller than the chapel, with one end semicircular, and two-thirds of the interior taken up by a raised stone platform, with a hollow in the middle like that of a cauldron, and a flue below the pavement to let in air. Doubtless this building was used for drying corn. A small piece of level ground with a ruined wall, standing lower than the chapel, is supposed to be the site of the convent garden. Below this is the cemetery, which contains a number of headstones. There are no lettered inscriptions, but several rude carvings, and on one slab there is a Greek cross. A little away from the cemetery is a cairn, which tradition points out as the grave of St. Columba's mother. Another rude building stands east of the chapel, and nearer to the sea are two half-ruined cells, such as were used by the Celtic monks as hermitages. Each has its own entrance, and a channel for drainage, and there is a passage between the two. It is obvious, says Dr. Ireland, that these buildings are the remains of a monastic establishment, and they are so ancient as probably to be the ruins of the actual convent founded by St. Columba. The objection that the early Scottish churches and monasteries were built of wood does not hold good in this instance, for it is based upon a passage in Bede, who was not born till one hundred years after the foundation of Hinba; and even if wood were in general use for church buildings, it is not unreasonable to suppose that in such a place as Hinba, where wood was not attainable, the builders would take the materials provided by Nature, the stones.

Nova et Vetera.

AN OLD DIPLOMA.

IN the JOURNAL of September 26th, 1908, p. 953, there appeared an obituary of the late Dr. Charles Ray, who died on September 10th, then one of the oldest members of the Royal College of Surgeons. He had been a fellow student at St. Bartholomew's Hospital with Sir James Paget and Mr. Luther Holden, and had served as dresser under Sir William Lawrence. His diploma of membership bore the date December 13th, 1836, and the document is remarkable owing to the fact that all the signatories were at one time or another Presidents of the College. Through the courtesy of Mr. Herbert Sieveking, who gave us an opportunity of examining the diploma, we are enabled to reproduce the signatures. A sketch of each of the distinguished surgeons whose names are appended to Dr. Ray's diploma may be of interest to some readers.

SIR ASTLEY PASTON COOPER. In 1836 Sir Astley Cooper was holding the office of President for the second time. He was elected President for the first time in 1827. As illustrating his ideal of the profession we may quote the address which he used to deliver on the occasion of the admission of candidates to membership. After formally admitting them, he proceeded to say:

And now, gentlemen, give me leave to tell you on what your success in life will depend.

Firstly, upon a good and constantly increasing knowledge of your profession.

Secondly, on an industrious discharge of its duties.

Thirdly, upon the preservation of your moral character.

Unless you possess the first, *Knowledge*, you ought not to succeed, and no honest man can wish you success;

Without the second, *Industry*, no one will ever succeed;

And unless you preserve your *Moral Character*, even if it were possible you could succeed, it would be impossible you could be happy.

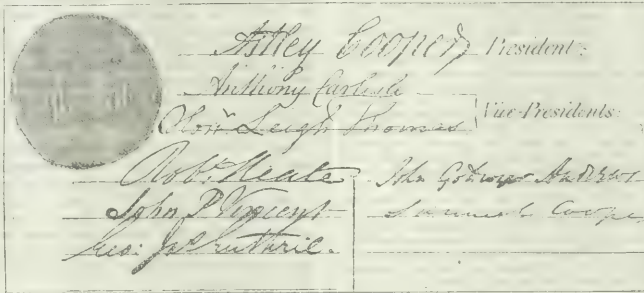

The address ended with a few words of encouragement. Astley Cooper himself was a conspicuous example of a preacher who throughout his life practised what he preached. His life is so well known that it need not be related here in detail. Only a few points need be touched upon. He was the son of the Rev. Samuel Cooper, D.D., and was born at Brooke, seven miles from Norwich, in 1768. His paternal grandfather was a surgeon at Norwich. He had also an uncle, William Cooper, who was for many years surgeon to Guy's Hospital. Astley in boyhood was more noted for mischievous behaviour and feats of daring than for attention to his books. Although he sobered down when he began to study his profession seriously, he was never a reading man. Indeed, when the *Lancet* in its hot youth began what was the revolutionary enterprise of publishing hospital lectures, Astley Cooper remonstrated with Wakley on the ground that his lectures were most incomplete and unsatisfactory, as he read few books and knew scarcely anything that was going on in surgery on the Continent. Wakley rightly pointed out that it was just the fact that the lectures were the genuine records of the surgeon's own experience that gave them their extreme value. All Astley Cooper's books were written from first-hand knowledge, and for this reason they remain authoritative while successive generations of compiled textbooks follow each other into oblivion. Throughout his life he constantly dissected. This, in the days before the passage of the Anatomy Act, naturally brought him into contact with the "Resurrection Men" and he told a

Committee of the House of Commons that there was no one, whatever might be his situation in life, whose body he could not obtain if he wished. He was always eager for information on all sorts of subjects, and however busy he was, if he found among his patients one who seemed to have some special knowledge, Astley Cooper did not grudge any time that might be required to extract it from him.

Though Cooper neglected his studies in boyhood, his early years were passed in an environment that must have gone far to supply any deficiency of school training. Among the visitors at his father's house were Canning, then fresh from Oxford; Dr. Parr, the famous scholar; the Lord Rosebery of the day; Lord Chedworth, and others. His father was a man of considerable attainments, and his mother was an accomplished woman. An operation by Mr. Donne which he witnessed at the Norfolk and Norwich Hospital first gave him, in his own

words, a strong impression of the utility of surgery and determined him to make it his profession. In 1784 he was sent to London to study under William Cooper. The uncle was, however, a somewhat rigid disciplinarian, and young Astley was by his own wish

transferred to the tutelage of Cline, then the leading surgeon of London. Cline was a disciple of John Hunter at a time when that great man was but little thought of by the profession. Cooper himself attended Hunter's lectures, and became one of his most ardent admirers. To Cline's influence Bransby Cooper attributes much of Astley's success in professional life. In one way, however, a shadow was for a time thrown by the master on the pupil. Cline was a close associate of Horne Tooke, Thelwall, and others, then in bad odour on account of their political opinions; like them he was a sympathizer with the leading spirits of the French Revolution. In a political sense Astley Cooper took the colour of his surroundings. He made rapid progress in his profession, becoming a lecturer on surgery before his pupillage had expired. So much was his heart in the work that he delivered his lecture as usual on the evening of his wedding day. In 1792 he made a trip with his young bride to Paris, where he witnessed some of the scenes of the Reign of Terror and worked in the hospitals. In 1800 he was appointed Surgeon to Guy's Hospital in succession to his uncle, who, however, did not actively favour his candidature. His political opinions were against him, but a timely sacrifice of these gained him the favour of the all-powerful treasurer, Benjamin Harrison. It should in justice be said that professionally Cooper stood head and shoulders above his competitors for the post, and the use he made of the large sphere of opportunity thus opened to him proved how worthy he was of the appointment. Till he became surgeon to Guy's, his progress in practice had been slow. He says himself that his receipts for the first year of his professional life were five guineas; in the second his fees amounted to £26; in the third to £64; in the fourth to £96; in the fifth to £100; in the sixth to £200; in the seventh to £400; in the eighth to £610. In the ninth, the year in which he became surgeon to Guy's, his income was £1,100, and afterwards it rose steadily, its high-water mark being reached in 1815, when his bank book showed earnings amounting to upwards of £21,000. But almost to the end his professional income was very large, and he received very handsome fees. The city merchants among whom he lived and practised for many years gave him five guineas a visit; one paid him £600 a year for periodical visits; and from another magnate whom he had cut for stone he got a thousand guineas. His mode of life

when he lived in the City is described by Bransby Cooper as follows:

His custom was to rise every morning at 6 o'clock, even during the winter. As soon as he was dressed, he went into his private dissecting room, where he worked till half-past 7 or 8. Scarcely then dressed his hair, and by half-past 8 he began to see the gratuitous patients, who came to him in large numbers at this early hour. His breakfast occupied but a short space of time. A glance at the newspaper, the rapid swallowing of two well-buttered hot rolls, his tea allowed to remain till it was sufficiently cool, and then drunk off at a draught, now and then the reading aloud of some paragraph from the newspaper which was likely to excite laughter, and the meal was finished. He would then suddenly jump up, and as he held the door in his hand, would turn round, and with one of his sweet, benign smiles, take leave of the party for the day; for none of the female members of the family, at any rate, would have the opportunity of seeing him again until the hour for dinner. He made a rule of never exciting his appetite at this meal by any of the usual dainties of a breakfast table. Although he cast many a longing glance at the bloaters, which were constantly sent to him from Yarmouth, nothing could induce him to break through this prescribed plan of abstinence from such stimulants. From the breakfast-room he went into his consulting room, to which a continued stream of patients would generally be pressing, until 1 o'clock.

The arrangement of the rooms in Broad Street was excellently adapted for the purposes to which they were applied. A large hall, an anteroom, and the consulting room, were in a direct line from the street door; to the right of the hall were two large rooms, which were occupied by gentlemen patients; while two drawing-rooms immediately above were appropriated to the reception of ladies. The hall had generally servants waiting for answers to notes for professional appointments; the anteroom was intended for the use of the patients who were next in succession to the patient then with Mr. Cooper.

The further room, on the right of the hall, which was the family dining-room, was generally full, from ten till twelve, of gentlemen waiting for their turn. These were anxious, perhaps, but still in a much less pitiable state than the occupants of the first room to the right. All who were admitted into this room had undergone some kind of operation, which had unfitted them for the present to leave the house. It was certainly an object of interest, at times partaking no little of the ludicrous, to me, as an inconsiderate youngster, on going into that room, to see six or eight persons, who had never set eyes upon one another before, contorting their features into expressions of all the kinds of suffering, from the dullest torment to the most acute pain; others moving in anxious restlessness to different parts of the room; while some one, more inquisitive than the rest, would be asking his neighbour with eager curiosity, what was the nature of the infliction he had undergone—still writhing, perhaps, under the effects of his own. These patients used to remain in this room until either their pain was eased, or Mr. Cooper himself dismissed them, after completing the operation to which they had been subjected.

The patience of the ladies, perhaps, was somewhat more severely tried than even that of the gentlemen, for as, in Charles's judgement, their occupation was not likely to be so important, nor their time so precious, he was accustomed rather to expedite the admission of the gentlemen than theirs. He most ungallantly used to observe, "there was more difficulty in drawing one lady than two gentlemen," meaning to imply by his term *drawing* the succeeding in withdrawing the lady from Mr. Cooper's presence. The manner by which the ladies exhibited their impatience was by frequently opening the drawing-room door, peeping over the banisters, or sometimes coming down into the hall and supplicating Charles to get them a speedy audience; requests which he knew well enough how to answer appropriately to the peculiar temperament of each applicant.

The anteroom was sometimes applied to another purpose than the legitimate one of merely facilitating the regular succession of patients, for Charles had some few chosen friends who knew how to pay their way into this room at once, without going through the more tedious ordeal of the usual waiting-room.

The attempts which Mr. Cooper's visitors made to induce his servant Charles to allow them to see him at once, perhaps out of their regular turn, were sometimes extremely ludicrous. No suffering was ever equal to theirs, would be tried. "Certainly Mr. Cooper would see them directly, if he had the least idea they were there." "It is not as if I should keep him a moment," and fifty other reasons were urged for the propriety of their admission. To all these arguments Charles turned a deaf ear, until that organ was rendered less obdurate by the chink of some more solid appeal; and then an excuse was generally found to allow him for this once to break through his usual plan. It is right to say, however, that when a mother spoke to him, or perhaps directed his attention to the sufferings of a child, he at once yielded to her entreaty, and gave her admission, often long before her turn.

Thus the patients were introduced in quick succession. I say quick, because the rap at the door of Charles—ever watchful of his master's interests, and not altogether perhaps forgetful of his own—and his exclamation, "A gentleman, Sir," were generally signals to depart which Mr. Cooper's Janus invariably made, as soon as he thought his master's name had been sufficiently occupied by the patient then with him.

When 1 o'clock came, it was announced that the carriage

was at the door; but at the same time, in quite a different tone of voice, it was not unfrequently whisperedd that the house was still crowded with patients. To this sometimes my uncle would listen, and say, "I will see one patient more"; then, perhaps, "I think there is time for a second." If, however, on any occasion, the urgent call of a third induced him to allow his admittance, as soon as he was gone, my uncle, looking at his watch, and finding perhaps half an hour elapsed, would certainly fly into a rage, abuse Charles for detaining him, and jumping into his carriage declare that he was certain the governors of the hospital would deprive him of his situation for his negligence.

At the hospital he would find a hundred students awaiting his arrival on the steps. He would immediately direct his attention to the dressers and elder pupils, asking them as to the important cases, and moved on into the ward *magni juvenum comitante catero*. After the visit to Guy's there followed a lecture at St. Thomas's. Then he would go through the dissecting room, noting anything worthy of observation. At half-past 3 he left, usually taking with him one of his pupils or dressers to write to his dictation or assist in an operation. At half-past 6 or 7 he reached home and took a rapid meal. Directly afterwards, if it were an evening on which he had to lecture, he would make a few pencil notes of the heads of his subject, hastily swallow two glasses of port, and at once go to sleep for a short time. Whether he lectured or not, he always had a number of professional visits to pay, and did not get home till midnight.

Astley Cooper's success was undoubtedly helped by his handsome presence and genial sympathetic manner; he was the opposite of Abernethy, whose roughness he used to say was worth £1,000 a year to him. But few men ever worked harder than Cooper, and no surgeon ever more fairly won the success that came to him. Work was his life, and when in his later days he gave up practice and went into the country, he returned to his work again in a few months.

He performed some remarkable operations, including his famous ligature of the aorta. Yet he says of himself that he was never a good operator where delicacy was required. To quote his own words:

He felt too much before he began even to make a perfect operator. For the operation of cataract he was quite unfitted by nature. Quickness of perception was his forte, for he saw the nature of disease in an instant, and often gave offence by pouncing at once upon his opinion. The same faculty made his prognosis good. He was a good anatomist of morbid as well as of natural structure. He had an excellent and useful memory. In judgement he was very inferior to Mr. Cline in all the affairs of life, and hence was continually walking upon a mine ready to explode under his feet. His imagination was vivid, and always ready to run away with him if he did not control it.

The following is another account of himself written in 1836:

As an operator for stone, aneurysm, hernia, and the removal of tumours he was excellent, prior to his giddiness, but after that time he was always afraid of being seized with them (attacks of giddiness to which he was subject after middle life) whilst he operated. He never was fitted for a very delicate operation. His strength consisted in the quickness with which he could decide upon the nature of a case, and the certainty almost of his decision being right, as well as the readiness with which he adapted his means of treatment. His diagnosis was really most remarkable. He obtained that decision from having made it a practice, when young, to see all the poor who would come to him, and thus he saw such a variety of disease as to make him as familiar with it as a parent with his child. His principle in practice was never to suffer any one who consulted him to depart without giving them satisfaction on the nature and proper treatment of their case.

His internal remedies were few and simple. He used to say:

Give me opium, tartarized antimony, sulphate of magnesia, calomel and bark, and I would ask for little else. These are adequate to restore all the actions of the body, if there be power of constitution to admit of the restoration, and disease, as far as I know, is either itself a deviation in the performance of some function, or at any rate is always marked by such a circumstance.

After referring to his success he proceeds:

For the benefit of the younger members of my profession let me say that this success may be always accomplished in a great degree. Be kind to everyone and most active to oblige. Learn your profession well, be an excellent anatomist, and understand well the practice and duties of your profession. Bend the force of your mind to some useful object, and be not multifarious and vacillating in your pursuits. Deep science is desirable to the man of fortune—useful science to the physician and surgeon. Let your zeal and industry be un-

bound. My own success depended upon my zeal and industry; but for this I take no credit, and it was given to me from above.

Elsewhere he gives a pregnant hint which all students of medicine would do well to take as a guiding principle in their work:

It is not the number of cases a surgeon has seen but it is his ready application of them which renders his knowledge of practical utility and constitutes him an efficient surgeon.

To a modern surgeon trained in the complicated ritual of asepsis, with the special sanctuaries, the officiating vestments and ceremonial lustrations considered indispensable, Astley Cooper's methods must appear crude and almost barbaric. He operated, says his biographer, in his consulting room to an extent that had never before been known in the home practice of any surgeon.

Tumours were removed, fingers amputated, and many other operations performed which, but a few years before were considered as feats in surgery. Infinite benefit arose to the public and to the profession by many operations being thus robbed of four-fifths of their horror. When a tumour was shown to him on such an occasion, which he at once saw required removal, if the subject were a lady, he would say: Now, my dear madam, this little swelling may become of importance to your life, at any rate your suspicions will render it a source of constant unhappiness to you, and therefore I am going to remove it," and as he began this address he rang the bell, and made signs which, without a word being said, sufficiently indicated to Charles what preparations were necessary. These were arranged so quickly, that Sir Astley had hardly finished his opinion before they were completed. It was rarely that a patient resisted his advice, for the dread of the operation was in a great measure removed by the simple manner in which he explained the propriety of submitting to it. In about five minutes often a patient was thus relieved from "a source of anxiety which had preyed upon the mind for months, and, moreover, many were saved the misery which must always attend the perspective (sic) view of a relative or friend being exposed to surgical operation."

In some cases, when he saw that a slight use of the knife was unavoidable, he would prepare himself, unobserved, by his patient, and under the pretence of a mere examination of the part, would at once execute the necessary task. Now and then this rendered the patient excessively angry, and I have heard a patient say, while wincing from the smarting consequent to the operation: "Sir, you had no right to do that without consulting me. God bless my soul! sir, the pain is intolerable. If you had asked me I don't think I should have submitted." "The very reason," my uncle would say, "that I considered it right to think for you, for now you will be well in about the same time that would have been occupied in making up your mind as to whether you would have it done or not." The patient by this time being restored to a somewhat more comfortable condition, from the gradual cessation of his pain, usually saw the force of Sir Astley's reasoning, and was grateful to him for the decision he had shown in his conduct.

It would be interesting to know the after-history of these impromptu operations. It must be remembered that these things were done in preanaesthetic days; the sights and the sounds must, one is disposed to think, have made Astley Cooper's consulting room present something of the character of a slaughterhouse. The difference between the surgery of Cooper's day and that of our own cannot be more graphically illustrated than by a story related by Dr. Badeley, who at one time used to go to his house to see poor patients. Cooper had removed a tumour from the head of George the Fourth, and was very anxious lest erysipelas should supervene. Yet on one occasion, after he had visited his royal patient, he said to Badeley on his return:

"Pray tell me if you see anything particular about me? for the King did not seem in good time; he looked hard at me from head to foot, and cannot understand why I do you see anything?" "Why," I said, "I should have put on a white cravat and a clean shirt or at least have washed my hands before I waited on His Majesty."

The fact is, says his biographer with engaging simplicity, that Sir Astley had performed a slight operation just before he went to the palace. Evidently common cleanliness counted for nothing in the days of our rude surgical forefathers.

Astley Cooper's writings are still valuable, for they are founded on direct observation, dissection, and experiments on animals. He spared neither trouble nor expense in their preparation, and his magnetic personality made all practitioners willing to help him by supplying particulars of cases. His chief works are his monographs on dislocations and fractures and on hernia. The completion of his

great work was prevented by his death, which occurred in 1841. He had worked to within a few weeks of the end. Every honour that can fall to a surgeon came to Sir Astley Cooper, and his name will always have a place in the history of surgery.

SIR ANTHONY CARLISLE.

Next comes Sir Anthony Carlisle, whom Charles Lamb described as "the best of storytellers and surgeons, who mends a lame narrative almost as well as he sets a fracture." It was from him that Lamb got the droll story about the three Quakers which he tells in his essay on "Imperfect Sympathies." Carlisle is also mentioned by De Quincey. He was born at Stillington, Durham, in 1786, and after attending the lectures of John Hunter, Baillie, and Cruikshank, and being the resident pupil of Mr. Henry Watson, surgeon to Westminster Hospital, he succeeded to the surgery on Watson's death in 1793. He held the office till his own death in 1840. He was president of the College in 1829 and again in 1839. He delivered the Hunterian Oration at the College in 1820 and 1826. Of the latter of these orations Sir Charles Bell writes to his brother, J. G. Bell:

To-day Sir Antony Carlisle (sic) delivered it (the Hunterian Oration). I heard him at the public dinner of the Hospital boast what he would do. I saw the moment he entered he would fail—that he had miscalculated the subject, and the time and the audience. He had a large volume of manuscript bore him; he was surrounded by a quantity of preparations suited to a course of lectures rather than to one discourse; and he had as many shell fish before him as you see in an oyster shop, and the folly or the wit to make the oyster the subject of the Hunterian Oration. He began with a supercilious confidence and after many interruptions, finally broke down after an hour and a quarter's delivery amid the noise and hisses of the audience. This was a fearful lesson to an audience.

Bell may not have been altogether without prejudice in the matter, as Carlisle had been appointed Professor of Anatomy to the Royal Academy in preference to himself. But the oration must have been a failure, for it earned for Carlisle the nickname "Sir Anthony Oyster." He was surgeon-extraordinary to the Prince Regent, and was knighted on the prince's accession. He held his appointment at Westminster Hospital till his death in 1840. He was a fair surgeon, and wrote several books, among them being *An Essay on the Disorders of Old Age and on the Means of Prolonging Human Life*; *A Lecture on Cholera*; *Practical Observations on the Preservation of Health and the Prevention of Diseases*; *Physiological Observations upon Glandular Structures*; and a pamphlet on man-midwives which gave great offence. In 1838 his conduct as surgeon to the Westminster Hospital gave rise to complaints as to his incompetency, and his clinical lectures were described as "frivolous, indecent, and absurd." In Mr. Fernandez Clarke's *Autobiographical Recollections of the Medical Profession* there is a description of one of his visits which fully bears out the description. A specimen of his stories, so much admired by Lamb, may be given: Sir Anthony asked his students if they had heard of the explanation given by a man who was asked why his nose was red. "I drink so much red wine," said the man. "I drink it red and p—— it white, and leave the red behind on my nose." Yet Carlisle must have been popular, for the publication of the report in the *Lancet* aroused such indignation among the students that Clarke on a second visit to the hospital had to flee for his life.

HONORATUS LEIGH THOMAS.

The next signatory, Honoratus Leigh Thomas, was born in 1769. On coming to London to study medicine, he brought a letter of introduction to John Hunter, who made an appointment with him for 5 o'clock the following morning. On presenting himself at that hour, Thomas found Hunter busy dissecting insects. He was a dresser under Hunter at St. George's Hospital, and also worked under Cruikshank the anatomist. After serving a short time in the navy, he was, on the recommendation of Hunter, who was surgeon-general, appointed assistant surgeon to Lord Macartney's embassy to China in 1792. In 1799 he saw service with the Duke of York's army in Holland. He married the elder daughter of Cruikshank, and in 1800 succeeded to his father-in-law's practice. He

was President of the College in 1829 and 1838. In 1827 he delivered the Hunterian Oration, in which he gave some interesting personal reminiscences of Hunter. Fernandez Clarke says of him:

The men whom we chiefly called in consultation occupied at the time prominent positions, but some of them contributed little or nothing to the literature of the profession. Honoratus Leigh Thomas, councillor, examiner, and twice President of the Royal College of Surgeons, was often called in by us. He was a very poor surgeon, very undecided, and avoided operations, but he was a shrewd practitioner in medical cases, for which his practice was mainly limited. He was familiarly known as "Dr. Thomas," and had a very extensive practice amongst the middle classes. He had in early life been a pupil of the celebrated Cruikshank, whom he afterwards assisted in his anatomical demonstrations, and lived with at his house in Leicester Place, Leicester Square. He subsequently married a daughter of Cruikshank, and succeeded his father-in-law as tenant of the house in Leicester Place, in which he practised for nearly half a century.

Mr. Thomas, as far as I know, made no contribution to the profession. He was courteous and able as an examiner, dignified as President, but he had no genius; there was nothing suggestive, nothing of *clan* about him. He was perfect in the sick-room; cool, attentive, kind, and in medical cases an excellent practitioner. Personally he was the *beau-ideal* of a physician—a tall and slender form, slightly bowed; a face sedate but kind; a forehead, though somewhat sunken, denoting great perceptive power; and a calm, somewhat subdued voice. He dressed truly "professionally"—black dress coat, waistcoat, and trousers, black silk stockings, and pumps; a spotless white cravat encircled his long neck; and a massive chain, with seals and keys, dangled from his watch-pocket. As I have said, he assisted Cruikshank in his anatomical lectures; but I am not aware that he was ever connected with any hospital or dispensary. He seemed to have a dread of operative procedure, though by no means in his palmy days a bad operator; but he would delay and delay surgical interference until his patient, tired out, would consult some more decided surgeon. He had a very extensive practice amongst licensed victuallers, and probably attended more members of that craft than any other surgeon of the present century.

Thomas died in 1846.

ROBERT KEATE.

Robert Keate was born in 1777. He was a younger brother of John Keate, the *plagiarist Orbitius*, who made his mark on the persons of so many of the future leaders in Church, State, and Society who passed under his birch at Eton. Robert Keate was apprenticed to his uncle, then surgeon-general to the army, and entered St. George's Hospital in 1793. In 1800 he was appointed assistant-surgeon to his uncle at St. George's, and thenceforward did nearly all his work. He retired from the army in 1810 with the rank of inspector-general of hospitals. In 1813 he succeeded his uncle as full surgeon at St. George's, and held the post until 1853. Keate spent his early professional life at sea. He was assistant-surgeon in the ship in which Prince William Henry, Duke of Clarence, was a midshipman. The Prince was grateful to him for his ministrations, and promised that if ever he became King of England he should be his body surgeon. The promise was fulfilled, and William the Fourth showed the same confidence in him when he was King as he had done when he was in the navy. In 1841 Keate was appointed sergeant-surgeon to Queen Victoria. He was proud of his appointments at Court, which he thought would be the basis of his fortune. He was President of the College in 1830, 1831, and 1839. But he said to Fernandez Clarke in 1853 or 1854:

My connexion with Royalty has been my ruin. I have attended four sovereigns and have been paid badly for my services. One of them, now deceased, owed me nine thousand guineas. The late King William IV always paid, but my journeys to Windsor to attend upon him and the Queen, as a rule, were a grievous loss to me. I have on many occasions, obeying a summons to the Royal residence, left a room full of patients anxious for my advice. The consequence eventually was that my practice declined, with respect to the public, and now that I am more than eighty years old I am a poor man. There is one exception, however, as regards my connexion with Royalty. That exception is the Duchess of Gloucester, who is my immediate neighbour. I visit her daily when she is in town, and the fees I receive in consequence from her form the staple of my income at present.

A characteristic story or two as to his relations with William IV may be quoted. He said:

I have no objection to relate to you one or two characteristic anecdotes of the late King. I was summoned down to Windsor to see the Queen. As it was "urgent" I immediately took post horses, and in two hours was at the Castle. I arrived so early that I was ushered into the breakfast room of the Royal

couple. The Queen was suffering from a pain in her knee, and she gave me a hint that the presence of the King might be dispensed with. According I said, addressing the King, "Will your Majesty be kind enough to leave the room?"

"Keate," said he, "I'm hanged if I go!"

I looked at him for a moment; I then said quietly but firmly, "Then, your Majesty, I will be hanged if I stay!" When I got to the door of the apartment, the King called me back.

"Keate," said he, "I believe you're right; I'll retire. You doctors do anything; but if a Prime Minister or a Lord Chancellor had presumed to order me out of the room, the next day I should have had to address his successor."

Once, said Mr. Keate, the Queen had determined to consult a homoeopathic practitioner.

"I hate humbug," said his Majesty, "and I won't allow any homoeopath to prescribe for my wife unless you are present."

"It is impossible, your Majesty," I said, "that I can meet Dr. D—; there is nothing in common between us."

"Well, then," was the rejoinder, "will you overhaul the prescription of the medicine which he orders for her, and see if she can safely take it?"

I promised to do so, and on the prescription being handed to me, I said, "Oh, your Majesty, she may take it for seven years, and at the end of that time she will not have taken a grain of medicine."

Keate contributed little or nothing to the literature of his profession, but, according to Fernandez Clarke, he was second to none of his time in the use of the knife. Clarke says his diagnosis was as a rule accurate, and he was a careful and sound practitioner. He was somewhat below the middle height, and his manner was bluff often to the degree of rudeness. This may have been acquired at sea. Although in later life he was irritable, he was incapable of any meanness of conduct either to a patient or to a brother practitioner. He died in 1857.

JOHN PAINTER VINCENT.

John Painter Vincent was born in 1776. He was appointed assistant surgeon to St. Bartholomew's Hospital, becoming full surgeon in 1816. He delivered the Hunterian Oration in 1829, and was President of the College in 1832 and 1840. According to the sketch of the Presidents appended to *Sir William MacCormac's Address of Welcome delivered on the Occasion of the Centenary Festival of the Royal College of Surgeons of England* on Thursday, July 26th, 1900, Vincent's opinion was highly valued by his colleagues in doubtful cases, especially by Lawrence. He was wonderfully skilful with his hands.

This was pre-eminently shown in his treatment of a case of strangulated hernia, which he often succeeded in reducing when others had failed. Over and over again the students, disappointed in their expectation of seeing him operate, would exclaim, "As usual old Vincent has tucked it up."

His deftness of touch was a natural gift, for Leigh Hunt, who was attended by him when a boy at Christ's Hospital, speaks of it. He describes Vincent as "dark like a West Indian." Clarke does not seem to have been so impressed by him as his colleagues. He says:

John Painter Vincent was occasionally called in for his opinion. He resided for many years on the north side of Lincoln's Inn Fields. Vincent was a peculiarly shy man, but was not without ability. People who did not understand him thought him slow and dull; yet he was a minute and careful observer, but he was not a good speaker. He failed to impress his patient, at first, certainly, with an idea of his real power. Those who knew him better had great confidence in him. In person just above the middle height, he walked quickly and somewhat clumsily. He had somewhat of the appearance and manner of a lawyer's clerk hastening to court. He dressed rather shabbily in black. His face denoted no great power. His features were regular, and he had a good forehead, but he never seemed to be on good terms with himself, and consequently was often not on good terms with others.

Vincent was the author of a volume entitled *The Principles of Surgery and of Observations on Some Points of Surgical Practice*. Mr. Skey said of him that he had a mind which revolted from any act of meanness or dishonour, and of whom it might be said without flattery he never sullied his integrity by a single ungenerous act during a long life of professional activity. He died in 1852.

GEORGE JAMES GUTHRIE.

George James Guthrie was born in London in 1785. He was early apprenticed to a surgeon, and worked as an assistant in the York Hospital; he became a Member of the College of Surgeons when not yet 16. He was almost immediately appointed assistant surgeon to the 29th

Regiment, and after five years in Canada he was ordered to the Peninsula, where he served almost uninterruptedly to the end of the war. He won the good opinion of the Duke of Wellington. In 1814 he retired on half-pay, and returned to London, where he worked under Bell, Brodie, and Abernethy. For two years he had charge of wounded men in the York Hospital. He is said to have been the first surgeon in England who used a lithotrite to crush a stone in the bladder. He founded the Royal Westminster Ophthalmic Hospital, to which he was chief surgeon. In 1823 he was elected assistant surgeon to the Westminster Hospital, becoming full surgeon in 1827. That appointment he held till 1843. He was President of the College in 1833, 1841, and 1854.

Guthrie lectured gratuitously for nearly thirty years on surgery to officers of the army, navy, and East India Company. His style was racy, and his teaching, being largely illustrated by his own experience on the battlefield and in the hospitals, was practical in the best sense. Fernandez Clarke says of him that he was brilliant as an operator, shrewd in diagnosis, and, though an uneducated man, he had all the natural attributes of a great surgeon. He died in 1856.

JOHN GOLDWYER ANDREWS.

John Goldwyer Andrews, the only one of the signatories whose name is not in the *Dictionary of National Biography*, was born in 1782, and was apprenticed at an early age to Sir William Blizard. He became a Member of the College in 1803. He was surgeon of the London Hospital, but contributed nothing to professional literature. He was President of the College in 1835 and 1843. He was a great collector of works of art. He died in 1849.

SAMUEL COOPER.

Samuel Cooper was born in 1780, and received his professional education at St. Bartholomew's Hospital. In 1806 he gained the Jacksonian prize at the College of Surgeons for the essay on "Diseases of the Joints," and in 1807 he published *First Lines of Surgery*, which went through seven editions. In 1809 appeared the first edition of his *Surgical Dictionary*, of which seven large and carefully-revised editions were published. After serving a year or two in the army, during which he was present at Waterloo, he devoted himself to the revision of successive editions of his two principal works, and also gained a considerable surgical practice. From 1831 to 1848 he was surgeon to University College Hospital and Professor of Surgery in the College. In 1845 he was elected President of the College of Surgeons. He died in 1848. Clarke calls him the Johnson of medical literature:

His great dictionary, though of a different stamp and written with a different object, was to surgery what Johnson's great work was to English literature; it is a monument to his memory illustrative of marvellous industry and marvellous erudition. The labours of no single man in our profession can be compared with those of Samuel Cooper in the compilation of his great work.

He was almost entirely unassisted, and the work was completed in three or four years. He rose early, and finished his literary labours before noon. Samuel Cooper is described as an excellent teacher; at the bedside he was painstaking, clear in diagnosis. As an operator he was careful, slow, and somewhat clumsy, but sure. Notwithstanding his lack of the brilliant qualities of his colleague, Robert Liston, he was a great favourite with the students.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.

THE annual general meeting of this society was held in the rooms of the Medical Society of London on May 27th, Dr. DE HAVILLAND HALL, Chairman of the Executive Committee, presiding.

The Chairman's Address.

Dr. DE HAVILLAND HALL congratulated the members on the excellent work done by the society. During the past year there had been 211 new proposals, the largest on record. There was a net gain of 140, bringing the total membership up to 2,723; of that total, 2,682 had insured for sickness benefit, 161 for life assurance, and 285 for

annuities. At the present time 28 members were drawing annuities, which amounted to over £1,000 a year. The amount paid in sickness claims had also created a record, being £14,447; the sickness experienced had been somewhat over the amount of the previous year; in fact, the sickness experience was gradually increasing. In the quinquennium ended 1898 the sickness experience was 75 per cent. of expectation; in the quinquennium ended 1903 it had reached 94, while in that just closed it was 97 per cent. of expectation. This, he thought, would afford an answer to certain members who suggested the extension of sickness provision beyond 65 years of age. If the sickness experience was growing under the present system, he was afraid that the sickness beyond 65 would prove something very startling. The Manchester Unity of Oddfellows showed that between 20 and 24 the sickness experience was 0.9 weeks a year, while between 65 and 69 it was 10.59 weeks a year, the Medical Assurance Society's experience worked out at about 1.2 days a year, if the society experienced ten weeks' sickness a year, the premium would have to be increased to such an extent that few members would be willing to pay it. The sickness fund now amounted to £126,126 as against £103,546 in the preceding year, a net increase of £22,579, but of this increase £9,557 was the share of the management and £7,827 the share of the investment fluctuation reserve fund. It had been decided that these two special funds should be merged into the Sickness Annuity and Life Assurance funds. The total funds of the society grew from £215,039 at the end of 1907 to £223,994 at the end of last year, an increase of £8,955. The members had all received the valuation report for the quinquennium just closed; it showed a satisfactory surplus in the sickness fund of £9,040 in addition to £6,306, the amount reserved against investment fluctuation. The surplus was sufficiently satisfactory to enable the committee to recommend the same rate of bonus to members retiring from the society at 65 as was paid in the last quinquennium—namely, ten guineas for each one guinea a week of sickness benefit assurance. The life assurance surplus of £4,303, with a reserve of £860, would allow a bonus of 15 per cent.; therefore, in future, all policies for £200 claimed during the present quinquennium would receive £230. In the annuity fund there was a small deficit of £2,781, which was more than covered by the reserve of £4,033. As was decided at the last general meeting, the sickness bonus would in future be paid out of the sickness fund, and not from the management fund. The result of the valuation was satisfactory, but as the rate of sickness experienced was steadily increasing, the society must be extremely careful to provide an ample margin for the future. At the last general meeting the question of the payment of members of the committee was referred to the committee for consideration, and he was glad to report that the whole of the committee felt that the work was a labour of love for their professional brethren, and that they did not wish to receive any pecuniary benefit; they were content with the thanks from the members of the society, and he hoped that the question would always be decided in the same way. As in the past, they were much indebted to the *BRITISH MEDICAL JOURNAL*, the *Lancet*, and the *Medical Press and Circular* for the notices published about the society's work. He tendered the warm thanks of the committee to Mr. Addiscott, their secretary, and Mr. Sutton, the assistant secretary, for the admirable way in which they conducted the business of the society. He also wished to express the thanks of the members to the auditor, and also to the trustees, who attended twice yearly at the bank to examine the investments; they were especially grateful to Mr. Hempton, who had given them useful suggestions about improved methods of showing how the society's funds were invested.

Report and Valuation.

The Chairman concluded his address by moving that the report of the committee and the audited accounts for the year ending December 31st, 1908, be received and adopted.

The CHAIRMAN, in reply to a question from Mr. GEORGE JACKSON, stated that the votes for Epsom College to which the society was entitled were confined strictly to the use of the children of deceased members.

The annual report was then adopted.

Two slight alterations of rules were adopted without discussion.

The CHAIRMAN then moved that the report of the actuary as to valuation of the society be received and adopted.

This motion was seconded by Dr. DICKINSON, and carried.

On the motion of Mr. GEORGE JACKSON, seconded by Dr. HAY, the officers for the year were elected.

Vote of Thanks to Chairman.

On the motion of Dr. BARKWELL, seconded by Dr. BRINDLEY JAMES, a hearty vote of thanks was accorded to the Chairman for presiding.

The reply of the CHAIRMAN brought the proceedings to a close.

MEDICAL DEFENCE UNION.

THE annual general meeting of the Medical Defence Union was held at University College, Bristol, on May 27th. Dr. STAMFORD FELCE, M.R.C.P., President, taking the chair at 4.30 p.m. There was a fair attendance of members, who listened with great interest to the excellent address on the work of the Union given by the President.

The annual report was adopted. The diversity of the claims for advice and assistance was shown by a schedule of some cases dealt with by the secretary, and by the legal report of the solicitor, Mr. Hempton. This set out the manifold nature of the matters referred to him: many of them had to be taken into court. It is interesting to note that of 128 matters placed in his hands, 40 were for libel and slander, 25 were claims for alleged negligence in treatment; 7 cases were in respect of suppression of unqualified practice, and the remaining 56 were matters as to appointments, partnership disputes, defence of members in actions under the Notification of Disease Act, and so on. Of the cases referred to the solicitor 70 were from the provinces, 45 from the metropolitan area, 4 from Scotland, 2 from Ireland, and 7 from Wales. Two cases were compromised at the special direction of the members concerned, and in one case an adverse verdict was given against the member concerned. In all other cases the Union was successful in its defence of the professional honour and reputation of the medical practitioner assailed. The statistics of the remarkable successes of the Union in the past have enabled the Council to make excellent terms with an insurance company of the highest reputation in the matter of indemnity insurance, the terms being within the means of all members of the profession. Those members who take out policies under the scheme of insurance set out in the annual report can congratulate themselves upon being in a position of great security; but the Council very properly cautions the members that there must be no relaxation in any way of the care and skill which should in all cases be exercised in dealing with the sick and suffering, and that the contract entered into between the insurer and insured presupposes that the same caution will be used in this respect as was used before indemnity insurance came into operation. With this caution we thoroughly agree. Insurance against third party risks is fully justifiable, and, as business as well as professional men, there is no reason why medical men should not secure for themselves indemnity for risks which, unfortunately, as the records of the Medical Defence Union have proved, are part of the professional life of medical practitioners. The security offered by the Defence Union is ample and satisfactory, and it is difficult to imagine what the loss to individual practitioners would have been had it not been constituted. As is pointed out in the Council's report, it can be said with absolute certainty that without the protection now afforded numerous practitioners would have been "greatly harassed and seriously embarrassed." The relief to those attacked, in being able to hand over their troubles to a skilled organization, amply equipped with special knowledge in dealing with medico-legal work, with ample funds and large experience, must necessarily be great.

The usual statutory resolutions were passed, and the report and minutes adopted. Dr. Stamford Felce, Dr. Victor Jaynes, and Mr. F. C. Larkin, F.R.C.S., were

unanimously re-elected members of the Council under Rule 28. A resolution directing the President to support the action of the General Medical Council in its endeavour to induce the Government to appoint a Royal Commission to inquire into the evils of unqualified medical practice was passed without any dissent. A vote of thanks to the President and Council for their arduous work for the protection of the members of the Union was carried unanimously, as was also a vote of thanks to the authorities of University College for the loan of the Library for the meeting.

ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1908.*

By the omission of a certain amount of statistical information it has been found possible to issue this report at an earlier date than in former years. The sectional reports have been summarized by the Deputy Chief Inspector, and this summary, combined with a good general index, makes the report for 1908 extremely convenient for reference.

The factory staff has been increased by 35, so that the total number of inspectors and assistants is 200. The number of places under inspection still continues to increase. At the close of 1908 there were 250,000 factories and workshops on the register. Owing to the general slackness of trade throughout the country the volume of employment shows a reduction. To this circumstance is partly attributed the decline in the year's total number of accidents.

White Phosphorus Matches.

Three years ago, at a conference in Berne, certain European countries decided to abolish the use of white phosphorus in the manufacture of lucifer matches, but the United Kingdom, and Sweden, Norway and Belgium did not fall in with the proposal. The times were not ripe for the adoption of the proposal, especially too as there had not been for three consecutive years in this country a case of necrosis, except in one factory. Subsequently, owing to an agreement among the manufacturers themselves, their attitude to this question became altered, especially in view of the absolute prohibition of the importation of phosphorus matches. The White Phosphorus Matches Prohibition Act was passed in December, 1908, and comes into force on January 1st, 1910. After this date white phosphorus matches may not be made or imported. When this Act comes into force all the special rules of 1899 will become obsolete.

Employment of Children in Scotland.

The Education (Scotland) Act, 1908, which came into force on January 1st of the present year, affects the employment of children and young persons. Previously certificates of exemption from school attendance could be granted to children between 12 and 14 years of age. By the new Act the age limit is extended to 16 years. The board is also empowered to make by-laws requiring the attendance at continuation classes of persons between 14 and 17 years of age who are not otherwise receiving a suitable education.

Laundries.

Laundries are now regarded as technically non-textile factories or workshops, accordingly as power is used or not, but they are subject to certain exceptions as to hours. Charitable and reformatory institutions also come within the influence of the Factory and Workshops Act, 1907.

Prison Employees.

The number of persons industrially employed in prisons in England and Wales is about 14,000: in "asylums" in England, Wales, and Scotland 10,000, and in inebriate reformatories in England, Wales, and Scotland 500. The figures for Ireland are not given.

Scheduled Diseases.

After the publication of the second report of the Industrial Diseases Committee the following further additions to the third schedule of the Workmen's Compensation Act, 1906, were ordered—namely, glass workers' cataract,

* Wyman and Sons, Fetter Lane, E.C. Price 2s 4d.

telegraphists' cramp, coxematous ulceration of the skin produced by dust or liquids, and ulceration of the mucous membrane of the nose or mouth produced by dust.

Employment of Mothers.

An inquiry is still proceeding as to the industrial employment of married women before and after childbirth, the results of which will appear in a forthcoming digest of the returns.

Sectional Reports.

In the Sheffield district there has been a decrease in the number of fatal accidents. Notwithstanding this circumstance, of the accidents which did occur 75 per cent. were preventable.

Although work in shipbuilding yards has been extremely slack, the number of accidents remains far too high. Many men were injured by articles falling upon them. A larger number of men were seriously injured by falls from staging, ladders, deck beams, etc. Although the attention of employers has been specially directed to this circumstance, no noticeable improvement has as yet been observed.

Cutlery Dust.

Messrs. C. Johnston and S. R. Bennett describe in an appendix the results of experiments undertaken with the view of devising means for the prevention of the inhalation of dust among operatives in cutlery. This paper, which was read at the Sheffield meeting of the British Medical Association in August last, is an indication of an earnest desire on the part of factory inspectors to participate in the various movements for the hygienic improvements of our industries so characteristic of our times.

The Flying Shuttle.

This appliance is still a cause of many serious accidents, for a perfect shuttle guard has not yet been invented.

Reports of the Lady Inspectors.

The lady inspectors have opportunities of eliciting information not always readily obtained by their colleagues. Many of the comments on industrial changes sent to Miss Anderson, the Principal Lady Inspector, deal with laundries. It would seem as if the day of the smaller laundries was drawing to a close. All over the country, not in the large towns alone, large laundries are being built.

With the small laundry will go many of the worst features of the trade; but will go also the small weekly wage of many a hard-working old woman who has kept herself off the parish or supported a sick husband by work in the smaller hand laundries.

The desirability of the air of workrooms being kept as pure as possible is shown by the tendency of the women to become anæmic and the possible development of tuberculosis. While work in a high temperature and a humid atmosphere is to be deprecated, a similar remark applies to work carried on in rooms wherein the temperature is little higher than that of the outside air.

As regards the industrial employment of children and young persons, attention is drawn to the greater loss of life in Belfast than in Manchester. At the age 15 to 20 the death-rate rises in Belfast to double that of Manchester, and yet the death-rate in the first five years of life shows that at this stage the chance of life is greater in Belfast. The higher death-rate in early womanhood is attributed to the strain of the long day in the hot and noisy mill or factory, leaving the workers no reserve of strength to support growth of mind and body.

The Report of the Medical Inspector.

Dr. T. M. Legge's report contains as usual much valuable information. During the year Dr. E. L. Collis was appointed an additional medical inspector of factories, a post to which he brings the experience gained during the ten years he acted as certifying factory surgeon for Stourbridge and surrounding districts. The appointment has been a most fortunate one, and has given general satisfaction. Already, in this 1908 annual report, there are indications of good work done by Dr. Collis.

Mention is made by Dr. Legge of the papers read and the discussions which took place in the Industrial Hygiene Section at the Sheffield meeting of the British Medical Association. Of the value of such a section at the annual

meeting there can be no doubt. It is anticipatory of, and complementary to, the work done by the Home Office.

Industrial lead poisoning shows an increase upon 1907. This may be due in part to the inclusion of lead poisoning in the third schedule of the Workmen's Compensation Act. The unhealthiness of some factories compared with others has long been known. This is well brought out by Dr. Legge. In one pottery the duration of employment for some women was only four months when plumbism supervened. There were 32 fatal cases of lead poisoning in 1908, 1 fatal case of arsenic poisoning out of 23 notified, and 47 cases of anthrax (7 of which were fatal), compared with 58 for 1907.

A short account is given of an investigation by Dr. Collis into the health of cotton operatives employed in card stripping, one of the dusty processes in a cotton factory.

Although known for decades of years it is only recently that the subject of deafness caused by certain occupations has formed the subject of careful inquiry. It is almost impossible for any person employed as a boilermaker to escape becoming deaf. To avoid the painful sensations caused by hammering, workmen are recommended to plug the ears with *plastiline* mixed with cotton. Not only will unpleasant sensations be thus prevented, but in all probability deafness as well. It is most desirable that this loss of hearing should, if possible, be prevented, for once established treatment is of no avail.

We have said sufficient in this brief review to show what a wealth of interesting information is contained in this report, and how favourably it reflects upon Dr. Whitelegge and his staff of competent inspectors.

THE SEVENTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

WITH a membership of some 3,000 and a programme divided up into seventeen sections, the Seventh International Congress of Applied Chemistry entered on its brief life on May 27th. Chemistry relating directly to medicine claimed attention in no less than five of the seventeen sections—namely, in the sections of physiological chemistry and pharmacology, of fermentation, of hygiene, of pharmaceutical chemistry, and of bromatology. In spite of the number of members, the attendance at the individual sections was not large, and in none of the five mentioned was there anything approaching a crowd. Photo-chemistry attracted a fair attendance, as did the sections dealing with analytical chemistry, explosives, and organic chemistry. The head quarters of the Congress were the University of London, and the rooms allotted to the various sections were well adapted to the requirements. A little difficulty was experienced by a few who desired to attend some interesting and instructive demonstrations given in connexion with the combined sections of physiological chemistry and fermentation at University College.

GENERAL ARRANGEMENTS.

An ideal congress, as far as we are aware, has never yet been held, although, according to all accounts, the Surgical Congress at Brussels last year came near to this. It is, therefore, not surprising that the present congress was by no means ideal, either from a scientific or from a social point of view. The sectional arrangements appear to have been carefully organized and fairly well carried out, especially in the matter of selection of important themes for discussion. There were, as usual, many, too many, papers in the programmes, but the number of absentees was unusually small. The practical nature of some of the subjects and their association with trade rendered it inevitable that a certain amount of puffing should be included. The young scientist, or would-be scientist, who is so fond of holding forth at the maximum permissible length at medical congresses to his own great satisfaction and to everyone else's discomfort was not freely represented, probably because those who had a real interest in bringing themselves into prominence were men of maturer years and vested property. A thoroughly friendly spirit pervaded the discussions, and while banter was not infrequently indulged in, a happy smile and international courtesy accompanied it. The wealthy potentate from both sides of the

Atlantic was accorded more time for his speeches than was wise on many occasions, and on more than one did the chairman fail even to keep such a speaker to his point. Long-winded effusions were tolerated in a measure which often was out of proportion to the interest of what was being said, but it should also be recorded that the audience was as much at fault as the chairman, for no signs of impatience or noisy interruption were indulged in.

The scientific value of the deliberations of the Congress can scarcely be estimated until some time has passed, but as far as the sections dealing with medical subjects were concerned, we would be inclined to believe that it was fair, certainly not below the average.

From a social point of view, we cannot congratulate the management. It would be difficult to imagine more confusion, less organization, and less comfort. Everything that should have been worked out and prepared a week before the Congress was hurried through at the eleventh hour. To start with, the information office had no information on any subject to give, save that tickets for this or that entertainment would probably be ready on the next day. Crowds of members of both sexes swarmed in the office, and the unfortunate officials were powerless to allay the wrath of those who failed to obtain what they considered they had a right to claim.

Part of the difficulty arose from the fact that the receptions at the Guildhall and Foreign Office were limited to 1,500 and 2,000 members respectively. It certainly appears unwise for a public body to issue invitations to a limited number of members. If the City of London or the Government of England wishes to entertain the members of a great international gathering, surely not much difficulty should be experienced in offering hospitality to 3,000. The banquet was arranged to take place at the Crystal Palace. We presume that a sufficiently large hall could not have been obtained more centrally, where over 2,000 persons could be fed sitting at tables. The distribution of the tickets for the banquet took place at a most inconveniently late and awkward hour. The plans of the tables bore numbers which were incorrect, and arrangements for the formation of parties were conspicuously absent. The feat of carrying this large number of ladies and gentlemen from Victoria to the Crystal Palace was performed quite creditably by the S.E. and C. Railway; but no one could have been pleased to learn that the trains would commence running at 6 p.m., so that those who did not live close to Victoria would have to break off work at an early hour to dress, journey to Victoria and find their train before that hour.

The private invitations extending hospitality to the members by a number of well-known and influential Londoners were better managed; any member desiring to attend one of the parties had to fill in an application form, and, provided that the number of invitations issued was not in excess of the number of guests arranged for, he received a formal invitation in the course of post.

THE ENTERTAINMENTS.

On Wednesday evening, May 26th, the Lord Mayor and Corporation of London received members of the Congress at the Guildhall. A number of distinguished personages were present, and a military band assisted in enlivening the preliminary proceedings. In the various apartments leading from the central Guildhall entertainments were given. The concert attracted a fair attendance, although our Continental friends could scarcely have regarded the performances as, musically speaking, high class. Dancing was indulged in by a few, while many looked on. The pictures, too, appeared to please a considerable section of the visitors.

On the evening of May 27th, His Majesty's Government, represented by Mr. Harcourt, received 2,000 members at the Foreign Office. Among those present were Lord Justice Fletcher Moulton, Lord Strathcona, various members of the Government and of the Governmental departments, and other members of Parliament.

On the evening of May 29th the Society of Chemical Industry entertained the whole Congress at the University of London, while in the afternoon a garden party was given at the Royal Botanic Gardens by the Ladies' Committee. Both of these entertainments were crowded and much appreciated. At the former, dancing, music, and refreshment—Wein, Wein und Gesang—assisted in enhancing the general enjoyment of those present.

THE BANQUET.

As has already been mentioned, the Congress Banquet took place at the Crystal Palace on Friday evening, May 28th. Over 2,000 guests were carried by special trains to the Palace, and on arriving found a suitable space reserved for promenading until the hour when the banquet was announced as ready. The President received the members shortly before 8 p.m., and at length the whole vast company was ushered into the central hall. Here a maze of tables was spread, but considerable difficulty was experienced in finding the allotted seats, as not only had a series of numbers been omitted altogether, but no names were attached to the places. Of the speeches, we regret that nothing can be said, as nothing could be heard. With difficulty the various speakers could be recognized as they rose, and it was curious to watch the gestures, without being able to perceive the least trace of sound. The band, conducted by a lady, and consisting of many ladies and a few mere men, performed the national anthems of the various countries, we presume in response to the toasts. At 10 o'clock a display of fireworks took place, and at about 11 o'clock the company, not much wiser, and certainly not in the least sadder, was conveyed in many specials back to London and bed.

THE INAUGURAL MEETING.

The Albert Hall is too vast a place for a gathering of under 4,000 persons. Its proximity to the London University, however, rendered the choice convenient, but there does not seem to be any reason why the public should not have been admitted to the balconies, if only to fill up the gaps which made so cold an impression in their naked, empty condition. At 3 p.m. Sir Henry Roscoe and Sir William Ramsay received Their Royal Highnesses the Prince and Princess of Wales at the entrance of the hall, while Sir Frederick Bridge played "God Bless the Prince of Wales" on the organ. As soon as Their Royal Highnesses had been conducted to the platform and had shaken hands with the chief delegates of the various countries attending the Congress, the Prince opened proceedings. He read a short speech, in the course of which he greeted the members not only in his and in the Princess's name, but also in that of the King. His Majesty was glad to think that the foreign representatives would visit Windsor Castle during their stay. Continuing, he said: "I fully appreciate the important part which chemistry plays in almost every branch of modern industry. We all recognize that without a scientific foundation no permanent superstructure can be raised. Does not experience warn us that the rule of thumb is dead, and the rule of science has taken its place?" He then declared the Congress open.

Sir HENRY ROSCOE in a short speech welcomed the foreign members in the name of British chemists, and thanked Their Royal Highnesses for gracing the meeting with their presence.

Sir WILLIAM RAMSAY made an excellent speech, delivered in clear tones, which could be well heard in every corner of the hall. He called attention to the fact that the King of Italy had filled the same position at the last Congress, held at Rome, as the Prince of Wales was filling. Professor Cannizzaro was the honorary president at the last meeting, and he was glad to think that this great man, whose work had done so much to make clear what was obscure and involved before, was still well and strong. Professor Paterno had been acting president at Rome, and he bade him a hearty welcome to England. Professor Witt, the acting president of the Fifth Congress, held in Berlin, was also present, and he extended a warm welcome to him also. After referring in sympathetic tones to the loss sustained by the decease of M. Berthelot and M. Moisson, he passed on to the discussion of the value of the association of scientific and technical chemistry. He pointed out that the chief difference between the pure science and its application consisted in an answer satisfactory to the technical chemist, but wholly irrelevant to the man of science, to the question, Will it pay? In conclusion, he said: "It has often been said that science is cosmopolitan, and knows no country. The existence of such a Congress as this is in itself a proof of the truth of this saying. We are favoured by the presence of representatives from every civilized State of the world. We are met together to discuss how best to develop the special branches of

chemistry to which we devote our lives; how to further their progress, and to mark the level to which they have already attained. A glance at our programme will reveal the many-sidedness of our endeavours. There is a city on the other side of the Atlantic whose motto, I think, is one of the noblest imaginable. It has the sanction of Scripture, and it is eminently practical. '*Philadelphiamanito*'—let brotherly love continue." Before resuming his seat, he spoke a few words of hearty greeting in French, German, and Italian, which evoked great and prolonged cheers.

Professor H. W. WILEY, Chief Chemist of the Agriculture Department of the United States of America, replied in the name of America. In touching on the importance of chemistry to the whole world, it was natural that he should give agricultural chemistry the first place. He stated that one service of chemistry was even more important than the service of applying science for the massing of wealth. That service was the development of prophylaxis in medicine. He instanced the problem of sanitation as one essentially chemical, including as it does the provision of pure food, pure air, pure water, ensuring pure activity of mind and body. Chemistry, he said, detects frauds and adulterations in all articles bought and sold. It exposes the manufacturer and the dealer who makes and sells any article deleterious to man, or under a false name or representation, to public scorn, and to the penalties of the law.

Professor ARMAND GAUTIER spoke in the name of France and particularly as the representative of the Minister of Public Instruction and of the chemists of his country. His colleagues across the Channel, he stated, held British chemists in high regard. The services rendered by Priestley, by Cavendish, by Dalton, by Humphry Davy, were mentioned in support of the statement that England had contributed very largely to the advance in the science. Next, he recalled the names of several great French and British chemists who had supplemented and improved each other's work, and by whose combined efforts marvellous strides had been accomplished. In conclusion, he acclaimed that the country of Lavoisier, Pasteur, and Berthelot offered that day a just tribute to the country of Cavendish, Davy, and Faraday, bringing to British science and activity the expression of its admiration and sympathy.

Professor Dr. OTTO WITT, President of the German Chemical Society, spoke in the name of Germany. Speaking in German in a voice which carried to the utmost corners of the vast building and with an enunciation which rendered each syllable distinct and clear, he bore greetings from his Government and from his society. Applied chemistry, he said, advanced in two distinct directions. It dealt with the chemical condition of raw material and advanced the interests of the industries of the world. The vivid interest which was being taken in this dual work was shown by the patronage of the rulers of the various lands, and in this connexion he offered his thanks to Their Royal Highnesses and to the King for their presence and sympathy.

Professor EMANUELE PATERNO, Vice-President of the Italian Senate, spoke in the name of Italy. Using his native language, and speaking with deliberation, after offering hearty greetings to the illustrious gathering of scientists and manufacturers, he passed in review the work done in England by many renowned chemists, and concluded by hoping that the endeavours of the Congress would be crowned with success.

The last speaker was Professor S. A. ARRHENIUS of Stockholm, who spoke in the name of all other countries. He spoke in English, and referred to England as the classical land of applied chemistry, and called attention to the fact that the study of hygiene had been very materially furthered by chemistry. He found that London has the lowest death-rate of all the large cities of the world, and believed that this was the fruit of applied hygiene. The present Congress included more biological chemistry than had been included in all of the former congresses, and in this fact he found a promise for the future.

The whole proceedings only occupied some forty-five minutes, and it must be regarded as a wise innovation to avoid a large number of speeches by innumerable delegates. On the present occasion Professor Arrhenius was entrusted with the task of replying for "Other Countries,"

so that the audience was spared a tedious and unprofitable couple of hours. The choice was one which may be taken as a compliment to the medical profession, since Professor Arrhenius has turned his attention to the chemical side of the study of immunity, and had certainly furthered our knowledge of immunity even if all his views are not acceptable to the majority of our profession.

The meeting broke up to the accompaniment of the National Anthem, during the playing of which Their Royal Highnesses left the hall.

THE SECTIONS.

The Theory of Colloids.

An interesting series of papers led to an animated discussion on the colloids in biology and medicine. Dr. HARDY opened with an account of the source of electric discharge on colloidal particles. Mr. BAYLES followed, and gave his views as based on his experiments on certain dye-stuffs. Working with Congo red, he found that solutions in water behaved as if in true solution. The osmotic pressure, however, demonstrated that the particles were in colloidal suspension, and that the dye exerted an electro-negative charge. The solution exhibited extraordinary sensitiveness to the action of electrolytes, but the osmotic pressure proved to be independent of any foreign electrolytic action. Ultramicroscopically, no particles could be discerned. The type of colloidal solution was therefore explainable on the assumption of large aggregates of infinitesimally small particles. He then spoke of the demonstration of the varying size of molecules when the solution was mixed with other colloids, and with calcium sulphate. The methods by which the osmotic pressure could be theoretically measured was described and adapted to changes in the solution, which follow when acids are added. All these observations, he claimed, lent considerable support to the kinetic theory of colloidal solution.

Dr. FREUNDLICH considered the whole phenomenon as one of adsorption. He gave a working formula, from which calculations could be made. Dr. BECHOLD and Dr. BOTTAZZI also read papers on the same subject, while Dr. GAUTIER and others took part in the discussion.

Titration.

Much amusement was afforded by the discussion on Dr. Friedenthal's paper on titration, with indicators, and the determination of reaction by the determination of hydrogen anions. The reader attempted to prove that his method gave more reliable results than those methods more commonly in use, and that since the results obtained under certain conditions by the other methods failed to tally with theory, it was justifiable to introduce new methods, so as to have control means of testing. He argued hotly against the acceptance of Ostwald's conceptions of the processes of ionization. Drs. DRUCKER and ROTHMUND contested the admissibility of his arguments, and elicited ready replies. Professor ARMSTRONG interposed with the stringent remark that he considered Ostwald's theory as "undiluted nonsense," and included the work of Arrhenius and Van t'Hoff in his caustic criticism.

Haemoglobin Reactions.

Dr. BUCKMASTER spoke of and demonstrated his pseudo-peroxydase reaction between haemoglobin and its derivatives and guaiaconic acid. The old guaiacum test, in which guaiacum and turpentine oil is used, demonstrated the presence of blood pigment, at all events when applied to the body fluids. Care must be exercised when testing urine in which iodides might be present. Since guaiacum is a substance of unknown composition and is variable, he found that disadvantages occurred in its use. Solutions of aloin acted in the same way. The leucobase of malachite green reacted in the presence of traces of hydrogen peroxide and iron-containing derivatives of blood pigments. Pure haematoporphyrin and haematoidin, being free from iron, did not give this reaction, nor did they give the usual guaiacum or aloin tests. The leucobase acted on blood solutions which had been heated to 200° C. for three hours, and this he regarded as proof that the reaction was not due to peroxydase.

Alcoholic Fermentation.

Drs. HARDEN and YOUNG demonstrated the processes determined in alcoholic fermentation. The action of yeast

juice, by which they mean the juice expressed from yeast cultures after grinding up with kieselguhr or sugar, depended on the presence of the enzyme, which is thermostable and non-dialysable, and the co-enzyme which is thermostable and dialysable. The using up of either or both of these constituents is followed by the cessation of the fermentation. They further found that yeast juice fermented glucose more rapidly in the presence of phosphates than in its absence. Yeast juice, however, contained a certain amount of phosphate, so that they were inclined to believe that the phosphate was a necessary condition for the fermentation. Attempts had been made to free the juice from phosphate, but this had not been completely successful. Samples of yeast juice deprived of the greater part of their phosphates exerted only a very faint fermentative action on sugar. If phosphate in certain proportions were added to the juice, the increase of fermentation on sugar, as evidenced by the production of carbonic acid, could be calculated from the amount of phosphate added. The curve of the action showed that the rate of ordinary juice fermentation proceeded very gradually, while when phosphate was added the curve rose rapidly, and, after a short time, when all the extra phosphate had been exhausted, again returned to the original rate. The authors were thus enabled to work out a formula, according to which sugar acted on by yeasts which must contain phosphate forms a compound of phosphate, which they term hexose-potassium phosphate. The enzyme reacting on this complex phosphate after the fermentation has been completed hydrolyzes the latter, and a sugar and free phosphate is again formed. If the phosphate be added in excess inhibition of fermentation is seen. From these observations it appears that phosphate is essential for alcoholic fermentation. The demonstration proceeded with extraordinary smoothness, and the increase of production of carbonic acid gas was most striking.

Other Demonstrations.

A number of other demonstrations of a highly interesting nature were also watched closely by a number of members. These included the production of formaldehyde by light in the presence of chlorophyll, the estimation of phosphorus by Neumann's method by Drs. PLIMMER and KAYA, some methods of investigating the action of drugs on the heart by Professor CUSHNY, and a method of blood gas analysis by Dr. BARCROFT.

Standardization of Disinfectants.

Drs. SCHRIVER and LESSING described their method of determining the rate of putrefactive change in the presence of varying quantities of antiseptics by measuring the rate of change in the substrata. This measurement is carried out by recording the change in the electric conductivity. The method and its importance have already received full consideration in the pages of the JOURNAL. Dr. RIDEAL and Mr. ORCHARD followed. The communication resolved itself into a reply to the paper published in the *Journal of Hygiene* by Drs. Martin and Chick. This paper has also been fully dealt with in the pages of the JOURNAL. The authors dealt with the suggested modifications of the Lister Institute test by (1) introducing large quantities of organic matter in solution or in suspension. This they regard as unwise, since under ordinary conditions of sewage the quantities of faecal material are never present in the quantities which are suggested, that is, 3 per cent. In sewage effluents, the Commission on Sewage recommends that not more than 3 parts in 100,000 should be permissible, so that the percentage suggested must appear inordinately high. (2) It is suggested that the test should be carried out at an optimum temperature of 20°C. The Rideal-Walker test is prescribed at a temperature with a range of from 15 to 17°C. that is, at room temperature. Disinfection is greater at higher temperatures, and therefore the suggestion departs from the conditions usually met with in practice. (3) The Lister Institute test requires the adoption of one definite time of contact for the valuation, and (4) requires that the time during which the disinfectant is allowed to act be lengthened to thirty minutes. The authors consider that in practice a disinfectant is required to destroy unknown cultures of different organisms in various kinds of media of unknown reaction at different temperatures and in the quickest possible time. The majority of disinfectants show increasing carboic coefficients with longer times of contact, but between two and a half and fifteen minutes

lies within the limits of experimental error. The authors further disagree with the deductions made by Martin and Chick in regard to the action of mercuric chloride, the action of which is arrested after a given time by the application of sulphuretted hydrogen.

Dr. CROEN interposed a paper on the disinfectant action of peroxide of hydrogen, in which it was maintained that this drug is more active in acid or even alkaline solutions than in neutral solution. Alkaline solutions were not taken into account on account of their instability. The action was weak at low temperatures, but rose rapidly with increase of temperature. Peroxide, he concluded, therefore, was not suitable for disinfection of drinking water or sewage, but was eminently suitable for the sterilization of instruments, hands, and other objects in surgical practice.

Dr. WYNTER BLYTH considered that bacteriological tests could not be used alone for standardization purposes, owing to the want of agreement in results obtained by different bacteriologists using the same standard method. In this direction he especially dealt with the Rideal-Walker test, which he stated gave extremely varying results. He found that heated organism tests did not always expose worthless or fraudulent disinfectants, and that chemical analysis combined with bacteriological tests appeared to be required for the proper control of disinfectants. He thereupon described his method of testing the commercial emulsions. The method depends on the de-emulsifying of the soap disinfectants by means of acetone, and subsequent treatment with ether and soda solutions. The details are somewhat complicated, and cannot be given in this place. More difficulty is experienced in de-emulsifying albumen emulsions, but this can also be done with acetone, and the liquid is then dealt with by petroleum ether. Professor KENWOOD also spoke of the variable results obtained by the Rideal-Walker test. In his reply, Dr. Rideal sought to show that the admission that the simpler test yielded variable results indicated that the time had not yet arrived to introduce a more complicated one.

Legislation.

Quite apart from those sections which might have been expected to contain matters of interest to the medical man, there were several papers read in other sections bearing directly or indirectly on medical subjects. This was especially true of the section devoted to Law, Political Economy, and Legislation affecting Chemical Industry. On the first day's session the chief business done was the carrying of a motion to the effect

That the committees of the various countries party to the International Convention for the Protection of Industrial Property be requested to consider the desirability of adopting the following provision: "The manufacture in one country of the Union protects the patentee against the revocation of his patent in all countries of the Union."

The meeting on May 29th was devoted chiefly to technical points of patent law, but several of the French members present pressed for a motion proposed by M. Fourneau, forbidding more than one registration in respect of the same pharmaceutical substance. German and English members, however, pointed out that this was an impossibility in their respective countries and of purely local interest for France. The motion, after an animated discussion, was withdrawn and reserved for the next Congress.

On May 31st an interesting and important paper was brought forward on behalf of Dr. C. A. von Martins on the transport of dangerous goods in merchant vessels. The author contended that the cases of damage by fire on board merchant vessels had considerably increased during the last few years, and quoted the following table, drawn up by the German Lloyd, showing that the packing, stowage, and declaring of dangerous goods left much to be desired. Between the years 1903 and 1907 inclusive the following cases of damage by fire were reported:

	1903.	1904.	1905.	1906.	1907.
Totally destroyed ...	29	25	35	34	42
Of these, parcelled goods ...	4	4	3	2	6
Partially destroyed ...	333	337	320	317	334
Of these, parcelled goods ...	95	94	101	103	127

The author had intended to propose that Great Britain should be invited to call a conference of maritime States interested to draw up and ratify suitable regulations. In his absence, however, the motion was not proposed.

In the afternoon, following a paper read by Professor BASKERVILLE (New York), a motion was proposed for the appointment of an International Commission to establish uniformity in the control of the escape of noxious gases.

At the last session M. HENRI TAFFE proposed that milk sellers should be obliged to supply only a certain minimum percentage of dry extract and butter in milk, and at the same time that the presence of a centrifugal cream separator near a dairy, as indicating fraudulent intent, should be regarded as a penal offence.

Starch.

In the other sections there was no lack of similar material. In the Starch Industry Section papers were read on various processes for the bleaching and conditioning of flour. Mr. R. WYMPER contributed a remarkable paper on the microscopic changes occurring in starch granules during the germination of wheat. The paper was based on a microscopic examination of grains extended over a period of growth of fourteen days. Inspection showed that thirty-six hours after the grain had become thoroughly moist the larger starch granules nearer the germ began to show signs of pitting. After three days the grains swelled, and in the centre of the flanks were considerably swollen, and in many cases were pitted by enzyme action. At this stage long oval starch granules, more resistant than the usual round form appeared, and by the ninth day the majority of the starch granules were of the oval form. As a result of these observations the author concluded that the larger and more mature starch granules were the more easily assimilated as plant food. On investigation by means of diastase and other reagents it was found that no general relation existed between their size and the ease with which they were attacked, but that it was almost universally true that the larger granules of any one starch succumbed more quickly to attack than the smaller granules of the same kind.

Oxidation of Atmospheric Nitrogen.

Saturday was the great day of the Electro-Chemistry and Physical Chemistry Section, when a full-dress debate was held on the possible means of the oxidation of atmospheric nitrogen, with an experimental demonstration by Professor BERNSTEIN. The room at the Central Technical Institute was crowded, and several members of the Congress were unable to gain admission. Other aspects of this important national problem were also dealt with by Messrs. N. CARO and C. WEISS. Throughout the week the agricultural chemists discussed various aspects of the same nitrogen problem, considering the value of the different nitrogen manures and the possibility of substituting biological for chemical methods.

Photography.

In the photo-chemistry department Mr. F. W. T. KROHN had a most sympathetic hearing when he argued in favour of the establishment of an international standard method of marking the speed of photographic dry plates and a definition of the standard conditions under which such speed tests should be carried out.

Other Sections.

To a certain extent the papers read in the Fermentation Section covered the same ground as those in Bromatology, for among the questions considered were various points in connexion with the analysis of brandy and of wines. Partly owing to the omnipresent influence of Dr. Wiley the question of standardization entered into the Section on the Industry and Chemistry of Sugar, where the standard temperature of 20° C. was recommended as the most suitable for taking all polarization readings of raw and refined sugars.

In the Explosives Section several important papers were read on the subject of mining explosions, dealing, for the most part, with the old question of the explosibility of coal dust mixed with air. Among the chief recommendations were the watering of the mines liable to be affected, the replacing of the normal floor in patches by concrete, and the liberal distribution of hygroscopic

salts about the mines. Evidence was brought to show that as a result of proper precautions being taken in the Westphalian district the number of mining disasters had very greatly decreased in recent years.

Several papers touching on matters of medical interest were brought before the Section on Inorganic Chemistry and Allied Industries. Mr. G. HARKER described a method for fire extinction and disinfection in ships and in other enclosed places. Briefly, his proposal is to utilize the gases from the ships' funnels, to pump this in large quantities into the holds of a burning vessel, and so to starve the fire of the oxygen necessary for combustion to continue. In support of Mr. Harker's claim that he has invented a suitable apparatus it may be mentioned that a Select Committee of the New South Wales Parliament has investigated the apparatus and recommended that it should be fitted to the salvage steamer used for dealing with outbreaks of fire on ships lying in Sydney harbour. Mr. Harker described some of the very stringent tests applied while his method was still in the experimental stage.

A sensational debate took place on the ionic theory and on how far it could be legitimately applied to explain chemical phenomena. Professor ARRHENIUS spoke energetically in favour of the theory, and Professor ARMSTRONG subjected it to a fire of vigorous criticism.

(To be continued.)

Medical News.

A MEMORIAL to Theodor Schwann, whose name is intimately associated with the conception of the living cell, is to be unveiled at Neuss, his birthplace, on June 6th.

THE annual dinner of the British Balneological and Climatological Society is fixed for Friday, June 11th, at the Piccadilly Restaurant, the President, Dr. Ernest Solly, of Harrogate, being in the chair.

THE Bowman Lecture of the Ophthalmological Society of the United Kingdom is to be delivered by Mr. Nettleship, at 5 p.m. on Friday, June 11th, at 11, Chandos Street, Cavendish Square. Mr. Nettleship will deal with some diseases of the eye illustrating heredity.

THE annual meeting of the Royal Medical Benevolent Fund Society of Ireland will be held in the Royal College of Physicians, Dublin, on Monday, June 7th, at 4.30 p.m. The chair will be taken by Dr. Andrew Horne, President of the College.

THE summer dinner of the West African Medical Staff will take place on Monday, June 21st, at the New Gaiety Restaurant, London. Members of the staff desirous of being present should communicate without delay with Dr. Froust, C.M.G., 78, Rodney Street, Liverpool.

THE East Suffolk County Education Committee has issued two leaflets from the school medical officer, one on vermin in the heads of children and the other drawing attention to the importance of cleansing the mouth, and particularly the teeth, of children.

It is proposed to establish a medical school in China under the auspices of Harvard University. This step is being taken in response to invitations of the Chinese themselves, among them being His Excellency Tuan Fang, Viceroy of the Kiang Soo. The approval of other Chinese officials has been obtained. A Board of Trustees, which includes such well-known names as those of President Charles W. Eliot and Drs. A. T. Cabot and W. Councilman, has been formed to administer the endowment fund. Ten medical graduates of Harvard are preparing to go to the East to work in the school.

A DINNER of the Glasgow University Club was held at the Trocadero Restaurant, London, on May 25th, when the chair was taken by the Lord Advocate, Mr. A. Ure, M.P. A gift to the club from Dr. C. O. Hawthorne of a silver snuff-box for use in the old Scottish style and fashion at the club dinners was gratefully accepted. The chairman, in proposing the toast of "The University and the Club," described the successful career of the club and its present satisfactory condition. Sir Donald MacAlister, in proposing a toast to "The Guests," referred to Sir Patrick Manson's important services in the sphere of public health work in the tropics. The toast was duly acknowledged by Sir Patrick Manson. After Mr. C. S. Dickson, M.P., had given "The Health of the Chairman" and that gentleman had replied the proceedings terminated.

British Medical Journal.

SATURDAY, JUNE 5TH, 1909.

MILK AND DAIRIES BILL.

THE regulations under which milk is produced and distributed vary in different parts of England and Wales. The requirements of the Dairies, Cowsheds, and Milkshops Orders apply to the whole country. They refer to the registration of dairymen, to water supplies, to the sanitary state of dairies and cowsheds, and to the prevention of the contamination of milk. The Local Government Board can make certain regulations by Orders, but it rests entirely with the authority to decide whether such regulations shall be made. In those districts in which the Infectious Disease (Prevention) Act has been adopted, the sanitary authority possesses the power to prohibit the sale of milk under conditions which are likely to cause the spread of infectious disease. Lastly, the councils of a few of the large county boroughs, including London, have special powers for the prevention of the supply of milk from tuberculous cows.

Those who are engaged in the dairying industry have over and over again urged that this exceptional treatment of particular districts should cease, and this is what the Milk and Dairies Bill, just introduced by Mr. Burns, seeks to provide. An abstract of the main provisions of the Bill will be found on page 368 of the SUPPLEMENT. It may be regarded as a codification of existing enactments and regulations with important additions. The machinery for preventing, without undue delay, the continued distribution of milk which is causing or likely to cause disease will be very much simplified. In cases of urgency, a medical officer of health may require a dairyman to stop a supply of milk for a period of ten days or less, and may agree upon what terms this course should be carried out. Where urgency is not indicated, a prohibition order may be made, on the report of a medical officer of health, by a sanitary authority. From this order there is an appeal to the Local Government Board, or, in certain circumstances, to the Board of Agriculture and Fisheries. An officer appointed by one of the Boards will hear the appeal, and, if he considers the order to have been unreasonable, full compensation will be paid the dairyman.

The clause of the bill which will meet with the greatest criticism is that which empowers the Local Government Board, after consultation with the Board of Agriculture and Fisheries, to make orders for specific purposes. Many of these purposes are quite legitimate, but there is at least one which should be looked upon with suspicion. It is that which places in the hands of the Board the power to say which are the authorities by whom the Orders are to be executed. This might in some conceivable instances

involve a question of principle which should not be decided by a Government department.

With the bill as a whole we are favourably impressed, and it may without presumption be claimed that this JOURNAL has had a very large share in preparing public opinion for the introduction of such a measure. The bill would indeed give effect to many of the most important recommendations made as the result of the inquiry into the methods of producing and distributing milk in England conducted by our special commissioner a few years ago. Among the omissions is one which must be regarded as very serious. It is apparently to be administered by the sanitary authorities and by the medical officer of health. One of the reasons why the bill is required at all is that the sanitary authorities have failed to carry out existing Statutes and Orders, and because the medical officer of health feels that if he presses for their enforcement he will be quietly relieved of his appointment. The omission in the bill is a failure to provide for its efficient administration. No greater security against capricious dismissal at the hands of members of district councils who may also be dairy farmers or the friends of dairy farmers, is given to medical officers of health, and, although the county council may take over the duties of a defaulting sanitary authority, it can only do so after a complaint has been made to it by four householders, or by a parish council, or by the sanitary authority of a district in which milk is received from the area of the defaulting district. It is true that the Local Government Board is empowered under certain conditions to make an Order directing an authority to carry out its duties, but the Order can only be enforced by *mandamus*. If an authority is so far neglectful of its duties as to become a defaulter, it will not be alarmed by a threat of *mandamus*. Alternatively the Board may make an Order empowering some person to carry out the duties of a defaulting authority at the cost of the authority. We cannot forget, however, that the Board has possessed this power since 1875 with respect to those sanitary authorities who have made default in providing their districts with sufficient sewers or with a supply of water—but there are still a large number of districts very ill supplied with water and where sewerage is urgently needed.

PHYSIOLOGY AND THE UNIVERSITIES.

PROFESSOR MAX RUBNER, whose researches on body heat are famous throughout the world of medical science, recently reviewed the position of physiology in university education in the opening address which he gave at the new Institute of Physiology in Berlin on May 4th.¹ Purkinje, in Breslau, was the first to found a laboratory of natural science; then followed the chemical laboratory which was built for Liebig in Giessen. The Institute of Physiology, the founding of which is coupled with the name of du Bois-Reymond, has a history of fifty years behind it—no more. But what an astonishing outgrowth of physiological science has occurred in that time! Think of the rise of bacteriological research and the separation of bacteriology as a separate science, and the enormous service rendered to man by such discoveries as those of Pasteur, Lister,

¹ Berl. Min. Woch., May 17th, 1909, p. 909. The address has been reprinted in a pamphlet, *Ueber die Stellung der Physiologie in Universitätsunterricht*. Berlin: Hirschwald. Price 60pf.

Koch, Behring, Manson, Ross, Bruce, Wright, and others, by which the world has been freed from the greater risks and pains of surgery, the heavy toll of diphtheria; taught how to expel malaria, yellow fever, sleeping-sickness from infected lands, a lesson which, learnt and put into practice, has rendered possible the greatest economic revolution of modern days; lastly, by which the world has gained an extension of the vaccination method of combating infection. Think of the extension of physiological chemistry, and the aids to diagnosis and treatment, the exact knowledge which has grown up, for example, about foods, metabolism, and the principles of dietetics. Think of the marvellous unravelling of the structure of the nervous system, and the foundations now laid for the science of neurology; of the rise of experimental pharmacology, the standardization, the discovery of the action and the synthesis of drugs.

If there is one of the numerous offshoots of physiology—shoots which in the last half-century have expanded into new sciences—if there is one which has led to least development when most was expected from it, it is the electrical physiology which seemed to du Bois-Reymond and his disciples the most likely to solve the riddle of life. The discovery of radio-activity has now revolutionized the whole of chemistry and physics, the atomic theory is shaken to its foundations, if not overthrown, and we must recognize henceforth that molecular construction is not the sole basis of metabolism and that other and unknown valences are at work in the living substance. Vast untrodden fields of research lie before us. Professor Rubner draws attention to two dangers of modern times—extreme specialization by which men are trained to work at some little piece of science and never gain that perspective of the whole by means of which great imaginative advances alone can be made. The second danger is the overproduction and publication of books and papers, nine-tenths of which are either rehashes of old material, often by the same pen, or contain accounts of poorly conceived, ill-conducted, and unco-ordinated inquiries carried out to maintain the outward signs of activities of laboratories which are continually being multiplied in number. It is impossible to keep in touch with the literature, to winnow the chaff from the grain, and the only way in which the difficulty can be met is by there being two sets of workers, one which chiefly experiments and has the imaginative faculty to conceive and the handicraft to perform, the other which specializes in some branch and chiefly reads, correlates, and publishes monographs dealing with the experimental advances made. The first group of men would find out what others have done in their line of research from the labours of the second group. The Germans, fortunately, are by nature well fitted to carry out more particularly the work of the second group—to the great content of the scientific world. Men of the first group are rare in any country, for the imaginative faculty is a gift of the gods.

In the new Institute of Physiology in Berlin there are the following departments: Chemical, physical—including photographic, operative, nutrition and calorimetry—bacteriology and microscopy. Much the same kind of division is made in the new Physiological Institute of University College, London, and at Oxford and Cambridge. Professor Rubner points out that suitable provision of instruments, which must

periodically be scrapped with advancing knowledge, is as necessary to medical education as armaments are to an army; he also points out that while for theoretical teaching it is no more costly to lecture to a hundred than to one, for practical instruction the cost in apparatus is multiplied a hundredfold. When will the Government of this country recognize this and adequately support our medical schools with grants for apparatus and laboratories, without which the training for the most important service in the country cannot be adequately given?

SPEECH FRIGHT.

EVERY one knows what stage fright is, and most of us who have had to recite speeches at school or have taken part in private theatricals have experienced the unpleasant and often paralysing feeling. It is not the raw novice who suffers most; it might almost be said that the greater the actor, the more frightened he is, especially at a first performance. One of the most celebrated of living actresses used to suffer so much on first nights that it was difficult to keep her from throwing up her part, and one of the most distinguished of living actors is in such a state of nervous trepidation and irritability when he is about to assume a new part that his friends dare hardly speak to him for some days before the first night. Orators are subject to the same infirmity. Cicero confessed that he could never mount the rostrum without a feeling that his knees were giving way under him. In his *Sixty Years in the Wilderness* Mr. W. H. Lucy relates the following examples of similar nervousness on the part of famous speakers of our own day: "On a night in 'June in the session of 1877 I observed Bright 'seated on the front Opposition bench hour 'after hour. The subject was a proposal to 'abolish capital punishment, and Bright had 'evidently intended to speak, and might, of course, 'have chosen his own time. He missed chance after 'chance, deferred his rising till after midnight, 'when the debate was about to collapse. Chancing 'to meet him at dinner the next night I made some 'remark about his delayed interposition, when he 'told me there had come upon him a species of stage 'fright that possesses all new members on first 'addressing the House. Even Mr. Gladstone was subject 'to this influence. This would be incredible to 'observers of his later manner were it not affirmed 'by his own testimony. In the diary of his second 'session he records how, preparatory to making a 'speech, he silently 'offered earnest prayer for 'Divine assistance.'" Lord Beaconsfield, we believe, impassive as he looked, was no stranger to the sensation.

In this country, where platform or post-prandial oratory is forced by national usage or social exigencies on so many reluctant victims, speech fright naturally is common. To some, indeed, public speaking is a task beyond their powers. They need not be ashamed of this. Many of the greatest masters of language might say with Alphonse Daudet, when invited to deliver an address: "Je n'ai jamais pu 'proférer une parole devant une audience quel- 'conque." But, except to those who deliberately shun social gatherings, there comes a time when they are called on to make a speech. What certain persons go through on such occasions amounts to

agony, and their hearers suffer in sympathy or are irritated by their struggles. Charles Darwin tells us that, when he was a student at Edinburgh, "one evening a poor young man got up, and after 'stammering for a prodigious length of time, blushing crimson, he at last slowly got out the words, 'Mr. President. I have forgotten what I was going to say.' The poor fellow looked quite overwhelmed. And all the members were so surprised that no one could think of a word to say to cover his 'confusion.'"

We have received a piteous appeal from a medical practitioner on behalf of a patient of his who occasionally has to speak in public, and who suffers at such times from "extreme nervousness and an 'all gone' feeling accompanied by palpitation"—in short from the symptoms of speech fright. The question is, Can medical art give relief in such a case? Our experience is that in many cases it can. In the particular case referred to, the administration of 20 grains of potassium bromide an hour before the dreaded moment has not been of much use. Our correspondent asks if a small hypodermic injection of morphine, not sufficient to cause drowsiness, would do good. We have no experience of this treatment, but it is within our knowledge that the great actress who has been mentioned was enabled to face the trying ordeal of the first night by means of seven drops of laudanum. She learnt to rely confidently on this medicine, which never failed of its effect. As the drug was given only on these special occasions she never contracted the opium habit. Years after learning empirically this method of preventing stage fright, we read that John Hunter, who disliked public speaking, never gave the first lecture of his course without nerving himself for the trial by taking thirty drops of laudanum; this gave him courage to face his audience. We think it likely that laudanum is used as a preventive of stage fright more frequently than might be supposed. Lord Erskine, the celebrated advocate, who suddenly appeared in the course of the trial of Queen Caroline, disconcerted the prosecuting counsel, for a great speech was naturally expected; after saying a few words, however, he fell into the arms of Lord Stanhope, who was sitting next to him. As Erskine was an old man at the time, it was thought that the strain and the excitement had proved too much for him. The truth, however, appears to be that he had drugged himself for the effort with opium, and had taken an overdose. Our readers do not need to be told that this method of conjuring away speech fright must be used with the strictest precautions against abuse.

We have seen it stated that an American professor was in the habit of giving 10 drops of fluid extract of gelsemium three times a day to students about to offer themselves as a sacrifice to examiners; the effect is said to have been that "all feeling of uneasiness was abolished during the ordeal, and the students were able to tell just what they knew." This treatment would equally well apply to speech fright, but we cannot testify to its efficacy from personal knowledge. As it is harmless, however, it might be given a trial. The very worst method of preparing oneself to speak in public is the arousing of "Dutch courage" by means of alcoholic stimulants.

As speech fright is a common affliction, and may seriously interfere with a man's success, we have thought it worth while to discuss the subject. Perhaps some of our readers will give us the benefit of their experience.

THE MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.

THE Medical Sickness, Annuity, and Life Assurance Friendly Society is well known to many of our readers. Its objects are described in the rules as the payment of a weekly allowance during sickness or disablement, of quarterly sums in old age, and of sums on the death of a member. The scope of the society's business, however, was restricted by a resolution passed in 1894, when it was decided to undertake no new liabilities under the heads of life assurance and deferred annuities, and its main scope now is provision for sickness or disablement.

The quinquennial valuation of the society's assets and liabilities as at December 31st, 1908, has been made by the secretary, Mr. F. Addiscott, F.I.A., and his report is now before us. In making the valuation the mortality and sickness tables of the Manchester Unity of Oddfellows have been used, and the rate of interest assumed has been $2\frac{1}{2}$ per cent. for the sickness fund and 3 per cent. for the life assurance and deferred annuity funds.

The number of persons assured against sickness has grown from 2,231 in 1903 to 2,682 in 1908, and the gross premiums have increased from £15,151 in the former year to £18,774 in the latter. The amount of the sickness fund stands at £323,625, as compared with £259,496 five years ago.

Notwithstanding the stringency of the basis of valuation of this fund, the results shown are satisfactory. The experienced sickness was less than the expected sickness by 3 per cent., and a surplus of £9,040 exists in the fund. It is, however, pointed out that this surplus has not arisen entirely during the past quinquennium, but is due to the allotment to the Sickness Fund of its share of the accumulated savings of the Management Fund. We refer below to the position of this latter fund.

During the five years ending 1908 the number of chronic cases of sickness—that is, of members who are permanently incapacitated—has just doubled, having grown from 23 in December, 1903, to 46 on the last day of 1908. All these persons are entitled to substantial annuities until they reach the age of 65. At each valuation of the society's funds a large extra reserve is stated to be made in respect of these chronic cases for the Medical Sickness Society is almost alone among assurance institutions in making a feature of this class of business.

The Life Assurance Fund is being gradually reduced as liabilities are discharged, and will eventually disappear altogether. At the date of valuation there were 161 members, as compared with 191 five years ago. A surplus of £4,303 has been found to exist in this fund, the amount of which stood on December 31st, 1908, at £22,670.

The Deferred Annuity Fund is not in quite so happy a position. Like the Life Assurance Fund, it is approaching a moribund condition, the number of members being 378, as compared with 435 at the previous valuation. A deficit of £702 was found to exist in this fund in 1903, and this has increased to £2,781 in 1908. The present deficit is more than covered by the Investment Reserve of £4,033 (5 per cent. of the fund), and is not considered by the Secretary to be large as compared with the funds in this branch. Whether this fund will ultimately prove sufficient to meet all claims is a question which only the future can determine, and depends to a considerable extent on the price of securities and the rate of

interest earned. It is by no means improbable that future movements of prices may be in an upward direction, in which case the deficit may be reduced or disappear altogether.

In accordance with the rules of the society, 10 per cent. of the full premiums is placed to the credit of the Management Fund. The actual cost of management, however, is little more than 5 per cent. of the premiums received, and there is now an accumulated balance of £14,382 in this fund. This balance has been divided *pro rata* among the three benefit funds, and, as stated above, accounts for nearly the whole of the surplus in the Sickness Fund.

Bonuses are recommended to be granted as follows: To every sickness member reaching the age of 65 during the current quinquennium, £10 10s. for every £1 ls. per week of sick benefit which he has secured during his membership; and, in the life assurance branch, an addition of 15 per cent. to all assurances which become claims during the present quinquennium. The bonus to sickness members is the same as that declared in 1904: that in the life assurance branch is 50 per cent. higher than the bonus declared five years ago.

In addition to the printed valuation report, we have been furnished with a list of the society's assets as at the date of the valuation. These are made up of £104,062, loans to various local authorities (over forty in number); £116,215 invested in Corporation, Colonial Government, and railway stocks; and £3,716 cash at bank and in hand. It is satisfactory to notice from the prices at which the stocks stand that the society is at present earning interest on its investments at rates which are well above those assumed for the purposes of the valuation. A report of the annual general meeting of the society on May 27th is published at p. 1371, where many of these facts will be found, but it has seemed well to call special attention here to the result of the quinquennial valuation; it shows that the society is in a sound financial condition.

With regard to life assurance, which the Medical Sickness Society is giving up, it may be added that the Medical Insurance Committee is able to arrange with an old and well-established office for life insurance for medical men on specially favourable terms, particulars of which can be obtained on application to Mr. Guy Elliston, the agent of the committee, at 429, Strand, W.C.

A "HOSPICE" FOR HEALING BY PRAYER.

WE learn from the newspapers that a "hospice" for the practice of "healing by prayer and the laying-on of hands" has been opened in London. The "hospice" has been established under the auspices of the Society of Emmanuel, the President of which is Mr. J. M. Hickson, whose name doubtless is by this time familiar to some of our readers. Among those present at the opening ceremony was Dr. Mylne, formerly Bishop of Bombay, whose account of the cure of a remarkable case of cancer—which was clearly proved not to have been a cancer—was quoted in the JOURNAL of May 22nd, p. 1253. Mr. Hickson was good enough to state to a representative of the *Daily Chronicle* that he has no antipathy to doctors; indeed, the hospice is to have two doctors on its staff. The healer thinks it is always desirable that the complaint from which a patient is suffering should be properly diagnosed; he likes to know the seat of the

trouble. Why a doctor should be needed to make the diagnosis before the prayer can be effectual seems a trifle mysterious; we do not wish to be profane, but it almost seems as if Mr. Hickson believed that Providence required to be told the nature of the case before the prayer of the healer can be answered! Mr. Hickson is reported to have said that he has another case of "cancer of the throat" under his care; the patient had undergone two operations before going to him, and is now apparently getting well. It is not clear whether the improvement is due to the surgical treatment or to the prayers of Mr. Hickson; however that may be, we should be glad to have full particulars of so interesting a case. But we doubt whether they will be forthcoming. In the *Evening News* we find an account of the cure of a cancer, which was furnished by a lady member of the society. The patient was a Bishop of the Church of England. "The doctors abandoned all hope of a cure." Then Mr. Hickson took the case in hand. He "arrived on the morning of a day on which the sufferer had to undergo an operation. Mr. Hickson prayed with him and anointed him, followed by a laying-on of hands. In the afternoon the surgeon arrived and made his examination. He was greatly surprised. 'This case puzzles me,' he said. 'There is the mark of a new wound, but the cancer has gone.'" "The cleric in question," added the lady, "is now perfectly well, and was with us the other day, but I believe the surgeon has not yet recovered from his surprise." We confess to sharing his surprise: we should have expected the prayer cure to work without making a wound. It is sometimes alleged that surgeons are too fond of the knife, but, granting that prayer may be more effectual, it would appear to act by the same method. Surgical prayer is surely a novelty even in spiritual healing. Once more we invite Mr. Hickson to give particulars of his cures sufficient to allow them to be tested in accordance with the ordinary rules of evidence. We do not wish to be understood as denying the power of prayer in relieving sufferers; without trespassing on the domain of theology, we need only say that to any one who knows the influence of the mind on the body, it is easily conceivable that an earnest prayer may bring about its own fulfilment in certain cases by the very intensity of the suggestive force which it calls into play. But we feel it our duty to point out that Mr. Hickson and the members of his society take upon themselves a heavy responsibility when they claim to have cured cancer and other organic disease without vouchsafing anything in the nature of proof.

THE TUBERCULOSIS EXHIBITION IN LONDON.

THE Tuberculosis Exhibition arranged by the National Association for the Prevention of Consumption was opened at the Whitechapel Art Gallery by the President of the Local Government Board on June 2nd. Mr. Burns delivered an interesting speech, which in its earlier parts was much interrupted by suffragettes. After they had been removed he proceeded to develop his thesis that while very much had been done to reduce the amount of tuberculosis in the country it is still a terrible drain on human vitality, especially during the working years of life, for 56 per cent. of the total deaths from consumption occurred between the ages of 20 and 45 years—the prime of life physiologically, economically, and reproductively. One-seventh of the total deaths among members of friendly societies was, he said, due to this cause, from 25 to 30 per cent. of all deaths between the ages of 20 and 45 in many large friendly societies being due to tuberculosis. That, Mr. Burns

said, meant wages wasted, contributions dissipated, and homes destroyed; one out of every three widows under 65 was either on the Poor Law or on some public fund, and it was difficult to estimate the economic waste and the loss to society, to relatives, to trade unions and friendly societies by the sickness, death, and disability which tuberculosis caused. Speaking generally, the disease was the child of poverty, the daughter of ignorance, the offspring of drink, and the product of carelessness. The statistics of London alone proved the truth of this, for whereas the general death-rate from consumption in London was 132 per 100,000, it was only 78 in Hampstead, but 215 in Finsbury with its one and two roomed tenements, its low wages, and its irregular work. London was saved from a worse position, and compared favourably with Berlin because of its system of small houses, but to obtain further improvement workmen must realize that to reciprocate the advice of a doctor, the State and the municipality, and of associations like the National Association for the Prevention of Consumption, they must spend their wages more wisely, selecting better food and paying higher rent, and also they must learn better to utilize the space at their disposal. The workman's front parlour was a fetish, a mausoleum for wax fruit, stuffed birds, and china dogs, which the children dare not enter, and where even the father would be a trespasser. If it was used it would add 25 per cent. at least to the breathing space of every workman's home. In new houses being built in London damp and dirty basements would not be found, and the intolerable cellar dwelling was doomed; wherever there was little light, damp air, dirt, and laziness, consumption found its lair, and in his judgement a good kitchen was the best pharmacy, a good table the best doctor, and cleanliness the best cook. He hoped soon to follow up the Notification of Tuberculosis Order by a circular to Poor Law authorities dealing with the conditions under which relief should be given to outdoor consumptive paupers, suggesting methods of self-treatment, and extending help in the direction of cure and prevention. Consumption was a house disease, almost a bedroom disease, and for its elimination he looked to higher wages, with wiser spending, less drink, and less betting, the money being spent on giving the wife and family better food and more house room. It was true that Parliament could do much, and municipalities could do more, but the individual could do more than both by personal attention. A vote of thanks to Mr. Burns was moved by Sir John Brunner, and seconded by the Mayor of Stepney, the Hon. Harry Lawson. Afterwards the company inspected the exhibition, which contains many interesting models, pictures, and diagrams, including one of an open-air school for consumptive children; there is also a collection of pathological specimens showing the effects of tuberculosis on various tissues and organs.

THE DANGERS OF SPINAL ANAESTHESIA.

At least 33 cases have been published in which paralysis of an ocular muscle has followed the injection of local anaesthetics into the spinal cord. In most of these examples the sixth pair was affected, in one case the fourth, once the third and sixth together, and in one patient there was complete ophthalmoplegia externa. The paralysis of the sixth nerve has, except in two cases, been unilateral. It makes its appearance from the fourth to the twentieth day, and usually disappears in from five to forty days. In one case published by Vossius it lasted for six months. The complication is not very rare. Ashe gives the figures as 4 in 400 anaesthetics, or 1 per cent. Werner and

Degreave as 2 per cent., Chapat and Pascalis as 1 in 258. Ricchi, of Boulogne, now adds another case to this long list.¹ The patient, a woman, received an injection of 2.5 c.cm. of a 4 per cent. solution of novocain for an operation upon the foot. Diplopia appeared two days later, and a squint developed. The paper is somewhat obscure as to the duration of the trouble, but it was more than twenty days.

THE FUNCTION OF THE PROSTATE.

THE physiology of the prostate gland can scarcely be said to be a closed chapter. The biological and chemical characteristics of the prostatic secretion are little understood, and apparently few physiologists have been able to determine the essentials of a healthy gland as opposed to one whose functions are impaired. The connexion between the prostate and the testes has long been recognized, and indeed in the last decade of the nineteenth century this was made the basis of operative treatment. Prostatic hypertrophy was treated freely by castration, but apparently with unsatisfactory results. With the development of the operation for the extirpation of the gland, the importance of the exact functions of this organ becomes evident. It is, therefore, a highly satisfactory circumstance that Professor C. Posner² has considered this subject from its scientific point of view. He started with the idea that, as in the case of the thyroid, the physiological importance of the prostate might be deduced from the symptoms noted after the complete removal. The matter, however, proved to be less simple, since those persons who are subjected to prostatectomy are usually advanced in years, and since the prostate gland is intimately connected with the sexual life, the loss of functional activity would not be apparent in persons who had lost this function as a result of increasing age. In a few cases in which sexual potency existed up to the time of the operation its loss may reasonably be ascribed to an accidental or unavoidable disturbance of the efferent ducts. That the prostate has nothing to do with the complete closure of the bladder is clearly shown by the results of prostatectomy, as well as by the experience of eunuchs, in whom the prostate atrophies early in life. Animal experiment has been resorted to to throw some light on the problem, and Posner states that although the work of Disselhorst, Steinach, Albarran, Serralach, and Pares cannot be accepted as bringing absolutely convincing proof, it may afford a basis for acceptable hypothesis. With regard to the relation between the vesiculae seminales and the prostate it appears that when the one is small or absent, the other takes on a compensatory growth. Removal of the seminal bladder and prostate in dogs, rats, and other animals, leads to interruption in the production of semen and abrogates sexual appetite. Feeding with prostate substance, however, stimulates these lost functions. The spontaneous reappearance of sexual power and semen containing spermatozoa which has been observed in a few cases after prostatectomy must be ascribed to the growth of traces of gland left. Posner therefore accepts the hypothesis that the prostate is a gland with an internal secretion, and that its functions are definitely of a sexual order. Professor Posner finds that diagnostic puncture of the testes, which he and Cohn have introduced, may be useful in deciding the question whether spermatozoa are formed and merely prevented mechanically from appearing in the ejaculation. He has observed a number of cases of true

¹ *Revue d'Ophthalmologie*, February, 1902.

² *Brit. Med. Jour.*, November 2nd, 1908.

azoospermia—that is, cases in which no sperm cells can be found in the puncture fluid—and found that the prostate gland in these cases was small, atrophic, or aplastic. This would mean that the prostate had been developmentally inhibited simultaneously with the testes, or that the cause lay in the prostate itself. Although he is not in a position to produce definite evidence in support of his contention, he believes that many of these cases result from a previous prostatitis, whether gonorrhoeal, due to a colon bacillus infection, or of the type spoken of as “aseptic.” Stern has found that chronic prostatitis is just as common a complication of diabetes as hypertrophy of the prostate. It might be of use to treat such cases with prostate substance or spermin. The results of implantation of prostate after extirpation of the gland, which Haberer is carrying out, may supply corroboration of this view. In conclusion, Professor Posner deals with the analogy between the prostate and the “rut” glands of some mammalian animals. It has been shown that the substance possessing the sexually stimulating smell in the hedgehog is derived from the prostate and not from the cloacal glands, as in the majority of other animals. In this respect, the function of the prostate would be less important to man than to the lower animals, and the stimulating quality of the prostatic secretion would be comparatively rudimentary.

INTERSTITIAL ECTOPIC GESTATION.

GESTATION in the portion of the Fallopian tube which passes through the uterine wall, known as interstitial or tubo-uterine pregnancy, is specially dangerous, as it is liable to early rupture, and gynaecologists teach that a pregnancy of this kind cannot proceed to term. Mr. Carr Roberts turned attention to this form of gestation in a report in the *JOURNAL*, vol. ii, 1882, p. 736, where he described a typical acute fatal case. The uterus and appendages were presented by Mr. Carr Roberts to the Museum of the Royal College of Surgeons, and were figured and described with notes on other cases in the museums of hospitals in London, by Mr. Alban Doran in the twenty-fifth volume of the *Transactions of the Obstetrical Society of London*. The specimen is figured in Bland-Sutton's and Hubert Roberts's well-known textbooks. Much has been learnt since Carr Roberts's case appeared in our columns. In a discussion on a memoir to which we will presently refer, Lovrich stated that there is a specimen in the museum of the University of Budapest illustrating an instructive case of interstitial gestation. The patient had died suddenly from rupture of the sac, and the midwife who attended her was accused of criminal abortion. Von Kubingi reported an instance in which a woman died in the fourth month after the uterus had been cleared of an “abortion,” but at the necropsy ruptured interstitial gestation sac was discovered. This discussion followed the reading by Dr. Windisch of a case in which interstitial gestation continued after death of the fetus at term.¹ He had enjoyed the great advantage of observing the pregnancy from the fifth week to the eleventh month. A healthy woman aged 25, who had already borne children, consulted Windisch at the end of September, 1906, for crampy pains and haemorrhages ten days after the period was due. She appeared to be about five weeks pregnant, and was advised to be careful lest abortion should set in. The pregnancy, however, went on undisturbed, and the fetal movements were first felt in the middle of December. The patient

expected her confinement at the end of May, 1907, but false labour pains set in, and the fetal movements ceased. There was much milk in the breasts in May. Then the abdomen grew smaller. Windisch suspected gestation prolonged over term, and operated on July 27th, 1907. He removed a big fetal sac containing a macerated female fetus over 20 in. in length. This sac encroached on the right cornu of the uterus, a portion of the uterine cavity was laid open, when the sac was removed and the breach in the uterus was closed by sutures. Windisch insisted that the gestation had primarily developed in the uterine portion of the right Fallopian tube, and brought forward microscopic evidence supporting his view. He considered that the isthmic and ampullar part of the tube had slowly dilated and allowed more room for the fetus. Tauffer, in discussing the case, agreed about the primary seat of the ectopic gestation, but considered that the sac had ruptured and a secondary abdominal pregnancy developed. He denied that the Fallopian tube ever dilates beyond the limits of the fetal sac, and most gynaecologists will, we suspect, agree with him. Several specimens illustrating early rupture of an interstitial sac have been added to museums in London since Carr Roberts's paper appeared in the *JOURNAL*, but the case above related is of special interest and should not be forgotten.

MEDICAL TESTIMONY AS TO CHRISTIAN SCIENCE.

It is by no means easy to bring the “testimonies” of healing by Christian Science to the touch as the accounts of its cures are generally so meagre and so vague that they cannot be accepted as proving anything but the credulity of the witness. It is interesting, therefore, to get some evidence that offers prima facie assurance not only of good faith, but of such knowledge of disease as to make the testimony worth considering. One of the medical men who have abandoned their profession to follow Mrs. Eddy is Mr. Walter Wilding, M.R.C.S., L.R.C.P., sometime medical officer of health for Hindley, Lancashire. Writing in the *Outlook* for March 28th, 1908, he states that he had periodically under his care for six or seven years a case of valvular disease of the heart complicated with diseased conditions in other organs, the ravages of each year leaving the patient in a worse condition, until a fatal termination appeared terribly near. “At this stage “of apparent helplessness and hopelessness,” Mr. Wilding goes on to say, “the prayers of a Christian Scientist were called for, and through them the patient was healed. The healing was complete, has been permanent, and the life has since then been “one of great physical energy and activity, full “of brightness, happiness, and joy. A Christian Scientist healed it by a purely mental process, “by that understanding of the efficacy of prayer “typed by Jesus at the tomb of Lazarus: ‘Father, “‘I thank Thee that Thou hast heard Me’—the prayer “of faith—the prayer that knows the availability of “the omnipotent power and goodness of our Heavenly “Father—God, from whom man derives all he is.” Mr. Wilding adds that while still practising medicine he witnessed the healing by Christian Science of several other cases of disease. “One was a young “man, whose knee-joint was quite disorganized by disease to little more than a pulp, “and the surgeons of one of our largest hospitals “urged that the knee-joint be cut out completely, as the only remaining hope of saving “his leg. Dreading this, he turned to Christian “Science, and was healed instantaneously.” Mr.

¹ Report of meeting of the Gynäkologische Section des Kgl. ungar. Ärztevereins, *Zentralbl. f. Gynäk.*, No. 19, 1909, p. 655.

Wilding says he examined the knee the day before and again the day after the healing, and, finding the cure perfect, it brought him to a crucial (*sic*) conviction that Christian Science is able "to improve on surgery as well as on medicine." He has seen "consumption healed in more than one case, the failing sight of old age return, paralysis in various forms disappear, a fracture of the large bone of the lower leg, after being ununited for four months, knit firmly together without any splint, first the crutch, next the stick, and, lastly, the 'limp' being discarded, and all in a fortnight." Mr. Wilding states, further, that Christian Science has brought seven years of health, strength, and freedom to his daughter in exchange for a condition of tuberculous disease in joints and lungs, which was rapidly carrying her to a grave. Now, we do not for a moment call in question Mr. Wilding's professional competence. He speaks with evident candour of that which he thinks he has seen. But if the events which he narrates really happened, we have got far beyond the region of suggestion and have entered the domain of the frankly miraculous. To the instantaneous *restitutio ad integrum* of a joint destroyed by disease there is scarcely a parallel to be found in the records of the most famous shrines of healing. Mr. Wilding's other cases, though wonderful enough, are not so entirely beyond human experience. But as to all of them our attitude is that of Dr. Johnson with regard to the immortality of the soul. When asked if he did not think there was evidence enough, he replied: "Sir, I should like to have more." Doubtless Mr. Wilding could easily supply more evidence of the cases which he relates; it would be interesting to the profession and useful to mankind if he could see his way to report the cases with all the details required in a medical report.

MINER'S NYSTAGMUS.

THIS important disease was the subject of a paper by M. Romi  e (Li  ge) to the Belgian Ophthalmological Society.¹ Last year the society devoted a whole sitting to a discussion on the same question,² which was duly abstracted in this JOURNAL. M. Romi  e's paper was an acrimonious polemic against M. Dransart, and the discussion which followed was evidently of a heated and personal character. The following data are, however, to be gathered from the papers read and the facts adduced by surgeons who joined in the discussion: (1) Miner's nystagmus is essentially a disease of the collier. (2) It is not found among miners in metal mines, who, equally with the collier, work in a bad light, and often in a cramped position, and who are obliged, as is the collier, to work with the eyes constantly elevated above the primary position. (3) It is never seen among boiler makers and repairers, who also work in a bad light, and in an even more strained position than the collier. (4) It is not more prevalent in gassy mines than in those free from firedamp. (5) Workers in photographic factories, who often work for hours in a feeble monochromatic light, and, where isochromatic plates are being made, in absolute darkness, never under any circumstances develop nystagmus. (6) The disease first appeared, or rather began to be described, at the time when the Davy lamp was introduced—that is to say, when the miner's light was reduced in intensity from 1 to 0.28. The lamps improved rapidly, the ordinary lamp now in use in Belgium—the Mueseler—giving a light of 0.44 candle power, and the Wolf

benzine lamp 0.87. (7) With the improvement in mining conditions, better ventilation, better light, and shorter hours of labour, the incidence of the disease shows a tendency to diminish. (8) It takes some years for the disease to develop, it being unknown in young miners. (9) About 20 per cent. of all colliers working underground are affected in a greater or a lesser degree, but only a small proportion of these men are incapacitated from work. (10) Hemeralopia is not a symptom of the disease, as has been stated by Court. Dransart, and others. If these statements are to be accepted as correct, then it would appear that nystagmus is not caused by position or by direction of regard alone, nor can it be due to feeble illumination alone, as Romi  e, Dransart, and others believe. Nor can the nystagmus be due to the action of the position on the semicircular canals. It appears that it is not inhibited, as Peters supposed, when the head is thrown back, unless at the same time the eyes drop. The only condition which remains over which is peculiar to colliers is the dead black surface with its crystalline fracture, and its myriad facets, which reflect and disperse the light in every direction. This environment is not present in the metal mine nor in the photographic dark room. It must in some degree be one of the causal factors. The *Bulletin* contains many statistics regarding the candle power of various safety lamps, which are of value to those interested in these lamps.

METHOD IN DIAGNOSIS.

EVERY one must often have felt discouraged by his failure to arrive at a correct diagnosis or indeed any diagnosis at all in cases which, regarded in the light of subsequent events and more highly-trained skill, appear perfectly simple. This loss of self-esteem is, of course, more frequently experienced by young practitioners who have not yet acquired the philosophical temper which comes with years and experience. It would be charitable to warn them at the onset that they will find diagnosis difficult or for the time being impossible in a not inconsiderable proportion of cases, while in a certain proportion the diagnosis at which they arrive will turn out to be wrong with consequent mortification and heart burning. From this point of view a lively correspondent suggests that the practice of medicine presents some resemblance to a game at billiards. If a man wish to learn to play well he must practise with more skilful players, and their services may not always be available. The great thing in medicine as at billiards is to be able to make sure of ordinary shots, and success cannot fail to accrue to the practitioner who never overlooks a lesion which he might reasonably be expected to recognize. If he will only make sure of this, if he will keep his standard of efficiency up to this by no means exorbitant level, his inability to accomplish feats of diagnosis need not disturb his peace of mind. There is, of course, no objection to his practising these strokes in his leisure moments, but he may miss them and still win the game. Gull used to say that mistakes in medicine are caused far more frequently by want of care than by want of knowledge, and want of care may usually be interpreted as want of method. Method in an observational science like medicine is what honesty is in daily life—a safeguard against wrong-doing. It should be cultivated for its own sake, without allowing discouragement at the occasional paucity of results to militate against its application. Then, in cases in which a consultation becomes necessary, the practitioner will not infrequently find his hesitation shared by the consultant; for in scientific medicine there can be no confident decision in the absence of the necessary data.

THE TENDER SPOT IN APPENDICITIS.

The significance and diagnostic value of a tender spot in association with appendicitis was discussed by Lejars a year ago, and Papin has recently analysed the views of various surgeons on this subject.¹ McBurney's spot, these French observers consider, indicates "an exaggerated precision" on the part of the surgeon after whom it is named, but they rightly add that his opponents go too far in the opposite direction in denying any appreciable value to this sign. It is certainly not pathognomonic of appendicitis; it is often absent in cases of that common disease, and may be present when the appendix is in its normal condition. In appendicitis pressure on McBurney's spot may cause pain referred to the umbilicus or epigastrium; whilst a tender area away from the "spot" is often observed when the inflamed appendix lies in its natural situation. Sonnenburg, Keith, Lanz, and Schröder make out that the "spot" corresponds more frequently to the ileo-caecal valve than to the base of the appendix; Keith, indeed, found that the base or point of insertion of the appendix lay about an inch below the "spot." Schröder, when assistant to Lanz, noted the tender spot in 119 cases operated upon by that surgeon. Within a few months 93 of the patients had no more tenderness over the "spot," but in the remaining 26 this was still tender on pressure. Lennander points out that as the abdominal viscera have no sensitive nerves, the parietal peritoneum is in appendicitis the seat of pain, most probably due to lymphangitis, or to adhesions involving the parietal peritoneum, and argues that on this account the tender spot cannot be well localized. Morris describes a tender point 4 cm., or 1½ in. from the umbilicus on a line drawn from the umbilicus to the iliac spine, and ascribes the tenderness to the effect of cutaneous pressure on the right sympathetic ganglion, which lies at this level. Often the pain in appendicitis is due to tension of the caecum distended by gas. Rovsing and Max make a diagnostic point of this fact. They press the caecum, and continue the pressure upwards along the ascending colon so as to drive the gas into the lower bowel; and this process is only painful when there is some caeco-appendicular affection. Lejars concludes that the careful clinical study of tender points is useful, but that no "spot" is pathognomonic. "Appendicitis," he warns us, "is not a disease to be diagnosed by the tip of the 'finger.'"

THE PRISON COMMISSION.

LORD ELGIN'S Committee on Scottish Prisons, which reported in 1902, expressed a very strong opinion that the presence of a medical member on the Prisons Board would greatly improve the administration and increase the confidence of the public. The recommendation was similar to that made with regard to England and Wales by Mr. Herbert Gladstone's Committee in 1895, and by the Grand Committee of the House of Commons on the Prisons Bill of 1897, to which the then Home Secretary gave effect on the first opportunity, and was similar also to that of Lord Cross's Commission on Irish Prisons, which resulted in the appointment of a Medical Commissioner. Lord Elgin's Committee was much impressed by the fact that in the great majority of instances in which difficulties have arisen in the management of prisons questions have been involved needing for their determination experience in medical requirements and practice. The recommendation has not been carried out in Scotland, which as a rule is able to boast that it precedes the sister countries in administrative reforms. An opportunity, however, is now afforded to the Secretary of State to

carry out this improvement, inasmuch as the chairmanship of the Scottish Prison Commission is now vacant. There was for long a kind of tradition that retired military officers made sufficiently good prison administrators, but this theory, which has not, so far as we are aware, been entertained outside the United Kingdom, has been condemned by results, and is now generally discarded. It is, therefore, very much to be hoped that, in the interests of efficiency, Lord Pentland will take this opportunity of carrying out the recommendations of Lord Elgin's Committee.

ON June 8th Convocation of the University of Oxford will be asked to make a decree gratefully accepting the gift of two sums of £2,500 each from Dr. C. Theodore Williams, who is an Honorary Fellow of Pembroke College, for the encouragement of the study of physiology and anatomy respectively. It will be proposed to establish two scholarships in physiology in relation to medicine, tenable for two years, one to be awarded in each year, and to establish one scholarship in human anatomy tenable for two years, to be awarded annually.

THE report of the Medical Officer of the Local Government Board for England for 1907-8 was issued this week. It contains the usual general articles on the administrative business of the department, on vaccination and the Government lymph establishment, on plague, and on cholera. The scientific investigations include an inquiry into the bacteria of sewer and drain air by Dr. Andrewes; on the defensive mechanism against pyogenic infection, by Drs. Andrewes and Horder; on the defensive mechanism in meningococcus infections, by Drs. Horder and Gordon; on mastitis in cows in relation to human sore throat, by Dr. Savage; and on *Streptococcus faecalis* and its endotoxin, by Dr. Sidney Martin.

General Medical Council.

NOTES.

The Business of the Council.—The General Medical Council concluded its session on Tuesday evening, at about 8 p.m., but it would not be quite correct to say that it had concluded its business by that hour. The greater part of the time of the Council during this session was occupied in hearing and considering two charges against medical practitioners, the one a charge of covering and the other of improper relations with a female patient—the decision in both cases being in favour of the accused practitioner—and in adjudicating on a rather long series of cases reported by the Dental Committee. There can be no doubt that the system rendered possible under the Dentists Act of making the Dental Committee a court of first instance, and the whole Council a court for final decision, very greatly economizes the time of the Council without in any way prejudicing the accused. Had this procedure not been in force, it is probable that the session would have occupied another day, or perhaps two. The Council did not sit on Monday—a bank holiday in England and Ireland, though not in Scotland, a circumstance which we believe aroused some dissatisfaction in the breasts of Scottish members. The reason for following this course, however, was, as we gathered from the President's address, that the printing establishment on which the Council depends for its daily programme and other necessary papers was closed on bank holiday, although, from our knowledge of the manners and customs of printers, we apprehend that this difficulty might have been overcome had the duration of the disciplinary inquiries been foreseen. As it was, several matters of general interest to the profession were inadequately dis-

¹ *Semaine Médicale*, March 11th, 1903; and *Rev. de Gynéc. et de Chir.* *Abd.*, January-February, 1903, p. 124.

cussed; in this connexion special reference may be made to the report of the Education Committee, which was really not discussed at all. We are glad to observe that the Council decided that the report of this committee should be on the agenda for the first day of its next session, which will commence at the end of next November.

Changes in Membership.—The death of Dr. Lindsay Steven, the representative of the Faculty of Physicians and Surgeons of Glasgow, and the retirement, on account of ill-health, of Dr. Pye-Smith, the representative of the University of London, and of Professor Young, the representative of the Victoria University of Manchester, led to the introduction of three new members: Dr. Knox, Dr. Frederick Taylor, and Professor Dixon Mann. This again led to certain alterations in the constitution of the committees, and it will be noticed with satisfaction that one of the direct representatives for England and Wales, Dr. Langley Browne, was elected a member of the Executive Committee, which may properly be looked upon as the most important committee of the Council since it meets on stated occasions at intervals between the sessions of the Council, and has most important functions in carrying on the work of the Council during these intervals and in giving general supervision to the preparation of business for the next ensuing session.

The Curriculum for the D.P.H.—During the session of the Council last November, Professor Thomson, the representative of the University of Oxford, drew attention to the regulation with regard to the Diploma in Public Health, which, while it laid down a curriculum of nine months, required an interval of one year before the candidate could present himself for examination, and argued that this was a hardship, especially to those graduates who might wish to proceed without delay to the Colonies. The point was referred to the Public Health Committee, which at this session presented a report strongly advising the Council not to alter the existing regulations. The main reason assigned was that the D.P.H. being a higher and post-graduate qualification, and one which had always been regarded in the light of an honours qualification, a sustained course of study was necessary and an interval of at least twelve months was commonly demanded by examining bodies between a pass examination and that for a higher qualification. It was pointed out further that the regulation is relaxed in the case of senior members of the profession, especially military and colonial officers serving abroad, who were permitted to complete their course in nine months. The Committee, however, considered that to extend this indulgence to junior candidates would be a retrograde step. Professor Thomson still adhered to his view that the regulation was unnecessary and even foolish, and met with a good deal of support, but the President pointed out that to carry out the curriculum adequately twelve months were still necessary, although, owing to a great deal of pressure, the Council had consented to the two half-years being telescoped, so that the curriculum could be completed in nine months. The view that it would be inexpedient to alter the period or alter the duration of the curriculum by recognizing the overlapping of the two periods of six months as a rule, prevailed, an amendment to refer back the report to the Public Health Committee was lost, and the report was approved.

Apothecaries' Hall in Dublin.—This body, through its representative, Dr. Adye Curran, announced that, notwithstanding the adverse expression of opinion by the General Medical Council, it was about to institute examinations of its own in preliminary general education, urging that it suffered by students who had taken their preliminary examinations under the auspices of the Royal College of Physicians and Surgeons in Dublin being thereby inclined to go to those bodies for their diplomas. The Council has no power to stop the Hall from carrying out its intention, which the President described as a purely domestic arrangement, as the examination was not recognized by the Council, and need not be accepted by any other licensing body. The perennial question of the reports upon the examinations of this body was raised also,

and it was urged that under the terms of the Act it was illegal for surgical examiners appointed by the Council to report to it, but that their functions were limited to the conduct of the examination. This point, it was urged, was emphasized by the fact that the new examiner in surgery is Sir Thomas Myles, a member of the Council. Reference was also made to the old Act of Parliament giving powers to the Apothecaries' Hall of Dublin, which elicited from Dr. Little, who also read from a copy of the Act, that the functions now assumed by this body were widely different from those laid down in the Act referred to.

Administration of Anaesthetics for Unregistered Dentists.—More than ten years ago, on December 1st, 1898, the Council adopted a resolution stating that: "Any registered medical practitioner who knowingly and wilfully assists a person who is not registered as a dentist in performing any operation in dental surgery, either by administering anaesthetics or otherwise, will be liable, on proof of the facts, to be dealt with by the General Medical Council as having been guilty of infamous conduct in a professional respect." A case in which a charge of this nature was made came before the Council during the recent session. The defendant admitted that he gave gas to a patient for an unregistered dentist on one occasion, but stated that the unregistered dentist was a patient, and that he was not aware when he went to the house that he would be asked to give an anaesthetic. He, however, further admitted that he had administered anaesthetics on a few other occasions, the last being during the autumn of last year, at a time when he was aware that the dentist in question was unregistered. The Council found the fact that the defendant had repeatedly given anaesthetics for an unregistered dentist proved, but on an expression of contrition and a promise never to repeat the offence, postponed judgement until its November session, informing the defendant that he would be required to produce evidence, particularly from his medical colleagues in the neighbourhood, as to his professional good conduct in the interval, and in particular that he had not repeated the offence as to which the complaint had been made.

Colonial Medical Legislation.—An ordinance has been enacted in Canada which prohibits, under penalty of £20, any person not registered from practising in the colony, whilst, in regard to dentists, it follows the lines of the home Dentists Act in merely prohibiting the assumption of titles. The difference in treatment may have arisen from the fact that it is the first step in dental legislation in the colony, whereas the 'medical enactment is not a new departure, but is a tightening up of existent legislation. In New Brunswick the Medical Act lately passed prohibits the act of practice. In both cases, therefore, a step in advance of our home Acts is to be noted. The New Brunswick Act, however, prescribes only a four years' curriculum, and makes no provision for the registration in the Province of practitioners whose names appear upon the British Register. Reciprocity with New Brunswick in the matter of medical qualification thus becomes impossible under the terms of our Act, and the union in this respect of the various Canadian provinces is not within sight. A new Act has been passed in Tasmania, but it is drawn somewhat closely on the lines of the home Acts, and only prohibits the assumption of medical titles by the unqualified.

The Charter of the British Medical Association.—The President in his address stated that the Lord President of the Council had forwarded to the General Medical Council a copy of the Draft Charter prayed for by the British Medical Association, with a request for any observations which the Council might have to make thereon. Sir Donald MacAlister suggested that the Executive Committee should examine the Draft Charter in consultation with the legal advisers of the Council, and report on any provision which might specially concern the Council. This course was, no doubt, followed, but no public announcement was made although the matter was, we understand, discussed in camera.

MANCHESTER AND DISTRICT.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN SALFORD.

THE medical inspection of school children in Salford receives special attention in the annual report for 1908 just issued to the Health Committee. The staff engaged in the work consists of the borough medical officer of health, who is also medical officer to the Education Committee; an assistant medical officer of health, the greater part of whose time is devoted to school work; and also a special ophthalmic medical officer, who attends at the education offices for two half-days a week to examine the sight of children specially sent to him. There are also two trained nurses, whose duties include the visitation of schools at such times as the medical officer of health may lay down, and six district sanitary inspectors, engaged in school work. The duties of the medical officer of health in connexion with the schools are chiefly organization, supervision, and preparation of reports, while the assistant medical officer, besides inspection of the children, has to report on the sanitary condition of the schools, to examine plans for any new school buildings and to report as to their sanitary arrangements, ventilation, and so on, to examine candidates for teacherships, and to give lectures on school hygiene to teachers.

Last October a scheme of inspection was submitted to the Board of Education under which each school department was to be visited by the medical officer three times a year. On two of these occasions he was to examine only new admissions and children to whom the teachers called special attention. On the third visit he was to be preceded by the nurse, who would inspect all the children and receive reports from the teachers, and then make a list of all children that required to be examined by the medical officer. In this scheme there was a careful distinction made between inspection and examination, and it was so obviously incomplete that the Board of Education pointed out that it did not comply with the regulations of the code, as it did not provide for medical examination of healthy children, but only for their examination by the trained nurses under medical inspection. A new scheme had therefore to be submitted which provides for examination by the medical officer at least once a year of all children between 5 and 6 years of age, and between 12 and 13 years of age, as well as for inspection of all the children and examination of cases selected by the nurses.

It would seem as if the Education Committee only proposed this latter scheme under compulsion from the Board of Education, for the report says that "almost half the time devoted to medical inspection will be spent in examination of children just about to leave school, and over whom little or no further influence can be exercised." There seems, in fact, to be some reluctance to carry out the full medical examination contemplated by the Board of Education. That the examination carried out was very incomplete is further shown by a note to the effect that in the statistics given of defects and diseases the figures do not include all cases.

More complete clinical examination would probably reveal an increased number, but the figures indicate those that require either medical treatment or special school treatment and as great a number of the milder cases as can be discovered by the examination which is practicable under existing conditions.

Thus it is quite impossible to know how far the statistics given represent the actual state of affairs. The fact is, and it might just as well be admitted, that the medical examination is imperfect; it is only "what is practicable under existing conditions," and with the present staff. If complete medical examination is to be undertaken, a larger staff will have to be appointed. The question then arises, Is a medical examination that simply detects well marked cases and a variable number of mild cases sufficient? On the one side it may be said that it is more statistics ought not to be the aim, that it is enough to detect cases that actually now need treatment, and that to examine medically every scholar to detect incipient disease would entail a prohibitive cost on the

rates. That seems to be the position taken by the Education Committee. On the other hand, it may be said that it is important to detect all the mild cases of every disease in order that they may be kept under individual supervision, as they are just the cases in which preventive treatment should be exercised, seeing that preventive treatment in mild cases, which can only be detected by careful medical examination, is quite as important as simple curative treatment of well-marked cases. This, of course, applies not only to Salford but to other towns, and there is some ground for believing that elsewhere as well as in Salford the cost of such medical examination is regarded as prohibitive.

Keeping in mind, then, the statement that all the mild cases are probably not included in the figures given, during the last four months of the year the following statistics were obtained, the number per 1,000 of scholars examined being given in each case: Well-marked tonsillar enlargement or adenoid growths were found in 25 per 1,000; suppurative middle-ear disease in 8.5; hernia in 0.85, all the cases being boys; rickets in 8.83, the proportion of boys to girls being as 3 to 2. The figure 8.83 for rickets is, perhaps, open to some doubt, for in an individual medical examination of 3,145 new admissions there were 20 per 1,000 showing rickets. Chorea was found in only 4 cases—that is, in 0.28 per 1,000; lateral curvature of the spine in 20; lung disease in 7.1; heart disease in 1.9; epilepsy in 0.85; tuberculous bones and joints in 1.7; tuberculous glands and cicatrices in 2.06; while enlarged glands "of an unimportant character" occurred in no less than 147 per 1,000. The feeble-minded children numbered 1.7 per 1,000. In the first eight months of the year pediculosis occurred in 30 per 1,000 boys and 45 per 1,000 girls, while in the later months of the year it was below 20 per 1,000 in each, the improvement being largely due to the inspection and to the firm stand that the teachers had been able to take. Careful directions had been given to parents for the treatment of *Pediculus capitis*, but there seems to be an ineradicable idea among parents that pediculi are caused by ill health or some idiosyncrasy, and there is the greatest difficulty in getting them to consent to cutting of the hair. Eye diseases and defects of vision were found in 44.5 per 1,000 during the last four months of the year, blepharitis being by far the commonest disease; 419 cases of defective vision were found and 400 pairs of spectacles prescribed. Of the refractive errors, compound hypermetropic astigmatism was the most frequent, accounting for 33 per cent. of the total; while simple myopic astigmatism was the least frequent, being only 2 per cent. of all errors. All these figures undoubtedly show good work by the present medical staff, and if more exact statistics are required the staff will have to be considerably augmented. Special attention has been directed to the teaching of hygiene, a series of evening lectures having been given to teachers and arrangements made for the teaching of elementary hygiene in all the schools. The syllabus of lectures appended to the report shows a careful selection of subjects on the whole, but there may be some doubt whether the treatment of sprains and wrenches, coughs, diarrhoea and sore throat ought rightly to find a place in such lectures.
